The section of active circulation and work of the descending meteoric waters between the surface and the ground-water level was called by Franz Posepny (1836–1895) the vadose or shallow region ("Genesis of Ore-deposits," *Trans. Amer. Inst. Min. Eng.*, xxiii., xxiv., 1893; reprinted as a book, 2nd ed., 1902). It has been long recognized by miners as the home of the oxidized ores, and the place of the work of the descending waters. The deep-waters are relatively motionless and their movements as far as visible are comparatively slow. But the really important feature of the ground-water as regards the filling of veins is the depth to which it extends. This remained a somewhat indefinite matter until L. M. Hoskins showed mathematically that cavities in the firmest rocks became impossibilities at about 10,000 metres. Down to some such limiting depth as an extreme the ground-water was believed by many to descend; to migrate laterally; to experience the normal increase of temperature with depth; the effect of pressure; the increased efficiency as a solvent peculiar to the conditions; and finally with a burden of dissolved gangue and ore to rise again, urged on by the "head" of the descending column. In its ascent it was supposed to fill the veins. Mining experience has, however, indicated that the known ground-waters are comparatively shallow and seldom extend lower than 500–600 metres. It is conceivable that during faulting and the formation of great dislocations this upper reservoir might be tapped into greater depths and set in limited circulations through deeper-seated rocks. But so far as these objections have weight they have greatly restricted the vertical range of the meteoric ground-waters as they were formerly believed to exist.

In contrast with the meteoric waters outlined above, other waters are believed by many geologists to be given off by the deep-seated intrusive rocks, and are generally called magmatic. We are led to this conclusion by observing the vast quantities of steam and minor associated vapours which are emitted by volcanoes; by the difficulty of accounting in any other way for the amount and composition of certain hot springs; and by the marked and characteristic association of almost all ore-deposits in the form of veins with eruptive rocks. That igneous masses have been connected with the formation of veins is further brought out by the following general consideration, which has hitherto received too little attention. Aside from pegmatites, veins rich enough to be mined and even large veins of the barren gangue-minerals are exceptional phenomena when we compare the regions containing them with the vast areas of the earth which have been carefully searched for them and which have failed to reveal them. As components of the earth's crust the useful metals except iron and aluminium are extremely rare. Some sharply localized, exceptional, and briefly operative cause must have brought the veins into being. The universal circulation of the ground-water of meteoric origin fails to meet this test, since if it is effective we ought at least to find veins of quartz and calcite fairly universal in older rocks. In North America, moreover, by far the greater number of veins which have been studied date from the Mesozoic and Tertiary times. The ore deposits of older date are chiefly of iron and manganese and can be satisfactorily explained in many cases by the reactions of the vadose region, or by crystallization from molten masses.

In summary it may be stated that the meteoric waters are of great importance and of unquestioned efficiency in the shallow vadose region, or, as named by C. R. van Hise, "the zone of weathering." In it the disintegration of rocks exposes them to the searching action of solutions, and the portions of ore-bodies already deposited undergo great modifications. The deeper and far more immovable ground-water probably extends to but moderate depth and is chiefly affected as regards movement by the head of waters entering heights of land and by local intrusions of igneous rocks. It is very doubtful if the normal increase of temperature with depth produces much effect. The meteoric waters are of altogether predominant importance in all surface concentrations of a mechanical character. The magmatic waters, on the other hand, seem to be of paramount importance and of great efficiency in producing the deposits of ores in the contact zones next eruptives, and in the formation of veins which are reasonably to be attributed to uprising heated waters in regions of expiring vulcanism. They start with their burden of dissolved metals and minerals under great heat and pressure, amid conditions favouring solution, and migrate to the upper world into cooling and greatly contrasted conditions which favour precipitation. Undoubtedly they are responsible for many low-grade deposits which have later been enriched by the action of descending meteoric waters. They are more copiously yielded, so far as we may judge, by acidic magmas than by basic ones.

The natural waterways are furnished by the cavities in rocks. They vary in size from very minute pores, where movement is slow because of friction, but where solution takes place, through others of all dimensions up to great fault-zones. The smallest cavities are the natural pores of minerals; cleavage cracks; the voids along the contacts of different minerals; cracks from crushing during dislocation; cellular lavas; volcanic necks; voids among the grains, pebbles, or boulders of fragmental rocks; joints; caves, and faults. So far as waters have deposited ores and yielded ore-bodies by subterranean circulations the latter are guided by some such controlling influence as these in all cases, and they will be selected as the governing principle in a large part of the scheme of classification. The types will be reviewed in the following order:—

I.—Of Igneous Origin.

A. Eruptive masses of non-metalliferous rock.
B. Basic segregations from fused and cooling magmas.
C. Deposits produced in contact metamorphism, most commonly by the action of intrusive masses on limestones.
D. Pegmatites.

II.—Precipitated from Solution.

A. Surface deposits.
B. Impregnations in naturally open-textured rocks.
C. Impregnations and replacements of naturally soluble rocks.
D. Deposits along broken anticlinal summits and in synclinal troughs.
E. Deposits in shear zones.
F. Deposits in faults.
G. Deposits in volcanic necks.

III.—Deposited from Suspension.

A. Placers.
B. Residual deposits.

IV.—Carbonaceous Deposits from Vegetation.

I. Of Igneous Origin.—A. *Eruptive Masses of Non-metalliferous Rock.*—Among the non-metallic objects of mining and quarrying which are of igneous nature, building stone is the chief. Granites, syenites, and other light-coloured rocks are the most important. These rocks occur as intrusive masses called bosses when of limited extent and diameter, and bathyliths when of vast, irregular area. The main point of importance is the jointing and cleavage, which should in each case yield blocks as nearly rectangular as possible so as to save tool treatment. Dark, basic igneous rocks in dikes, sills and surface flows are employed for macadam, and are often of excellent quality for this purpose.

B. *Basic Segregations from Fused and Cooling Magmas.*—A few ore-bodies, of which the best-known involve iron, are believed to result directly in the igneous processes by which molten rock cools and crystallizes. Thus magnetite, one of the common iron ores, is a widely distributed component in the eruptive rocks, rarely if ever failing in any variety. It is one of the first minerals to crystallize, and it possesses a much higher specific gravity than the other constituents. There is reason, therefore, to believe that, forming in some molten magmas in relatively large quantity, it sinks to or toward the bottom of the mass until the latter is at least greatly enriched with it, if not actually changed to iron ore. If the molten rock, after passing through a stage of partial crystallization, moves toward the surface of the earth, the body of ore may occupy almost any position in it other than the bottom. The flowing of the magma in original movements or from pressure sustained in subsequent metamorphic processes, or both, may give the ore the lenticular shape which is quite characteristic of magnetite bodies the world over. Almost all iron ores of recognized eruptive origin contain titanium oxide in amounts from a few units to over 40%. They are most frequently found in dark basic rocks. These ores are not at present of much commercial value because of the difficulties of treating titaniferous varieties in the modern blast furnace practice, but there is little doubt that in the near future they will be extensively mined.

Non-titaniferous magnetites, which often form lenses in gneissoid rocks of more acidic character than those with which the titaniferous are associated, are likewise believed by some observers to be of igneous origin, but there are equally positive believers in sedimentary deposition followed by metamorphism.

Besides magnetite, chromite is a characteristically igneous mineral and is always found in the richly magnesian rocks. Whether the relatively large masses which appear in serpentine are direct crystallizations from fusion, or whether they have segregated from a finely disseminated condition during the change of the original eruptive to serpentine, is a matter of dispute, but the general trend of later opinion is toward an original igneous origin. Although not strictly an ore, corundum is another mineral which is the direct product of igneous action.

A form of ore-body which marks a connecting and transitional member between those just treated and those of the next group is furnished by the sulphides of iron, nickel and copper which are found in the outer borders of basic igneous intrusions. Observers differ somewhat as to the relative importance to be attributed to reactions purely of the nature of crystallization from fusion or those brought about by the agency of gases or other highly heated solvents in the cooling stages. The most important example is afforded by the mingled ores of nickel and copper which are developed in their largest form in the region of Sudbury, Ontario, Canada, and are now the principal source of nickel for the world.[1] The ores are chalcopyrite and pyrrhotite, the latter containing throughout its mass at Sudbury the mineral pentlandite, a rich nickel-iron sulphide and the real source of the nickel. With the base metal there are also found minute traces of the metals of the platinum group. Wherever these ore-bodies have been observed they invariably occur in the borders of intrusive masses. The sulphides constitute an integral part of the rocky mass, which shows almost no signs of alteration or vein production in the ordinary sense. Only some slight rearrangements have subsequently taken place through the agency of water, but all this is a small factor in the total.

C. *Ore-Bodies produced by Contact Metamorphism.*—Great bodies of igneous rock have often been forced in a molten and highly heated condition through other rocks when at a distance below the surface of the earth. After coming to rest they have remained during the cooling stages for long periods in contact with the surrounding walls. All molten igneous magmas are more or less richly charged with aqueous vapour, doubtless in a dissociated state; with carbonic acid and probably with other gases, especially those involving sulphur. During the cooling stages the gases are emitted and carry with them silica, iron, alumina and metallic elements in less amount, of which copper is the commonest, but among which are also numbered lead, zinc, gold and silver. If the rock standing next the intrusive mass is limestone, the silica and iron, and to a less degree the alumina, combine with the lime to the elimination of the carbonic acid and produce extensive zones of lime silicates, of which garnet is the most abundant. Disseminated throughout these garnet-zones are large and small masses of pyrite and chalcopyrite, oftentimes in amounts sufficient to yield large ore-bodies. Again in the limestone outside the garnet-zones, but none the less closely associated with them, are bodies of sulphides containing copper. The copper ores of Bisbee and Morenci, Arizona, of Aranzazu near Concepcion del Oro, Mexico, and of many other parts of the world not yet studied in detail are of this type. The eruptive which most frequently produces contact zones is of a marked acidic or siliceous character, since among eruptives these are the ones most richly charged with gases. When the copper ores are of low-grade in their original deposition it often happens that processes of secondary enrichment, which are later described, are required to bring them up to a richness which warrants mining. Less often than copper appear lead, zinc or gold ores in the same relations.

D. *Pegmatites.*—One other phase of eruptive activity needs also to be briefly mentioned before passing to the discussion of the ore-bodies, which have hitherto chiefly occupied students of the subject. In the regions surrounding intrusive masses of granite we almost always see dikes or veins of coarsely crystalline quartz, felspar and mica radiating outward, it may be, for very long distances. They are believed to be produced by emissions from the eruptive similar to those which yield the garnet-zones just mentioned. The veins are technically called pegmatites. They are characteristic carriers of tin and of minerals containing the rare earths, and less commonly are known to yield gold or copper.

II. Precipitated from Solution.—A. *Surface Deposits.*—The chief ore-body under this type is furnished by iron. The peculiar chemical property possessed by this metal of having two oxides, a ferrous, which is relatively soluble, and a ferric, which is insoluble, leads to its frequent precipitation from bodies of standing or comparatively quiet waters. Ferruginous minerals of all sorts, but more particularly pyrite and siderite, pass into solution in the descending oxidizing or carbonated surface waters, either as ferrous sulphate, or as salts of organic acids, or ferrous carbonate, the last-named dissolved in an excess of carbonic acid. On being exposed to the atmosphere when the solutions come to rest, or to the breaking up of organic acids, or to alkaline reagents, or sometimes to fresh-water algae, the hydrated sesquioxide $2Fe_2O_3, 3H_2O$ is precipitated as the familiar beds of bog ore. The ore usually forms earthy aggregates or crusts and cakes, but may also, as in the interesting case of the Swedish lake deposits, yield small concretions. Bog ores are not very rich in iron and are apt to have much sand and clay intermingled. If subsequently buried under later sediments they may become dehydrated and changed to red hematite, as in the case of some of the Clinton iron ores of the eastern United States. These widely extended beds in the lower strata of the Upper Silurian are often oolitic red hematites, consisting of concentric shells of iron oxide and chalcedonic silica, deposited around grains of sand. The most extensive of all ore-beds of this type and the mainstay of the German and Belgian smelting industry, are the Jurassic ores, locally called minette, of Luxemburg and the neighbouring territories. Three principal and several subordinate beds are distinguished, which furnish a product ranging from 30 to 40 % of iron and between 1 and 2 % of phosphoric oxide (P_2O_5). They are generally believed to have been deposited on the bottoms of embayments of the Jurassic sea. The iron was furnished by the drainage of the land and was precipitated, according to Van Werweke, as silicate, carbonate, sulphide and as several forms of oxide. More than two billions of tons are believed to be available. Very similar deposits occur in the Cleveland district, England, in the Middle Lias.

---

[1] A. H. Barlow, "On the Sudbury Deposits," *Geol. Survey of Canada Ann. Rept.*, vol. xiv., part H; A. P. Coleman, *Ann. Report of the Ontario Bureau of Mines*, vol. xiv., part iii. (1905).

In the presence of much organic matter which creates reducing conditions, concretions and even beds of spathic ore or black-band may result and afford the ores of this type extensively utilized in the Scottish iron industry and formerly of some importance in the eastern United States.

The brown hematites often have more or less manganese, and manganese ores themselves may result by closely related reactions, since manganese is very similar to iron in its chemical properties. Aluminium is yielded by deposits of bauxite, the hydrated oxide, which in the states of Georgia and Alabama, of the United States, are the result of surface precipitations. In the depths it is believed that pyritous shales exist. The oxidation of the pyrite supplies sulphuric acid which takes into solution the alumina of the shales. Rising to the surface along a marked series of faults, the aluminium sulphate meets calcium carbonate in an overlying limestone, and the aluminium hydrate is precipitated as concretions at the vents of the springs.

Of scientific importance but as yet not of commercial value are the siliceous sinters deposited around the vents of hot springs which yield appreciable amounts of both the precious and the base metals. While surface precipitations in every particular, they are yet chiefly important in casting light on the processes of vein formation in the depths.

Non-metallic minerals which are deposited from solution on the surface of the earth are the salines, rock-salt, related potassium salts, gypsum and the rarer nitrates. The alkaline chlorides and gypsum are derived, in nearly all cases, from impounded bodies of sea-water, which, exposed to evaporation with or without constant renewal, finally yield beds of rock-salt and related minerals. Shallow estuaries cut off from the sea, it may be by the sudden rising of a bar during a heavy storm or brines impounded in deep bays with a shallow connexion as in the "bar theory" of Ochsenius, have given rise to the great stores of these minerals which are so extensively mined. The potassium compounds have only been found as yet in large quantities in the Stassfurt region of Germany, and seem to be due to the fact that in this locality the mother-liquors of the rock-salt deposits failed to escape, and were evaporated to dryness. The nitrates are chiefly obtained in northern Chile and are the result of the reaction of nitrogenous organic matter, upon alkaline minerals and under conditions where there is enough but not too much water.

Another very important mineral found in surface deposits formed from solution is asphalt. It has happened in various parts of the world, but especially in the island of Trinidad, in the Carribean Sea, that petroleum with an asphalt base has reached the surface, has evaporated, and has become oxidized so as to leave a residuum of asphalt suitable for street-paving or other purposes. So-called pitch-lakes are afforded which may be of great commercial value.

Again, if large sheets, crusts, stalactites and stalagmites are deposited from calcareous water by the escape of the solvent carbonic acid, beautiful ornamental stones are afforded, generally known as Mexican onyx.

B. *Impregnations in Open-textured Rocks.*—In a number of instances in various parts of the world naturally open-textured rocks have been discovered so richly impregnated with the metalliferous minerals as to be ores. The enriching minerals have been introduced in solution, and the solvent has found its way through the rock because of its natural character, and not because geological movements have opened it. Porous sandstones are one of the most common cases. Deposits of silver ores have been extensively mined at St George in southern Utah, consisting of films of argentite and cerargyrite, which have been precipitated upon fossil leaves, sticks, and in the sandstone itself. Over wide areas in the northern United States, copper in various minerals has been discovered in sandstones of Permian or Triassic age. At Silver Cliff, Colorado, silver ores have impregnated a volcanic tuff, while at the Boleo mines in Lower California tuffs yield copper ores. In at least two of the great copper mines on Lake Superior the native metal impregnates a conglomerate, and in a number of others it has enriched a cellular basalt, filling the blow-holes with shots and pellets. In the Commern district between Bonn and Aachen, sandstones of the Triassic Buntersandstein contain knots of galena, distributed over wide areas as impregnations. Organic matter is believed to have precipitated the galena by a reducing action upon percolating solutions of lead.

All these porous rocks have been fed by solutions which have entered along waterways, clearly due to faults or some extensive breaks which have provided introductory conduits. The solutions have then been tapped off from the main passages by the porous rock. They are, therefore, closely connected with faults.

Non-metallic minerals in the form of petroleum and asphalt may also impregnate sedimentary beds or other rocks of open texture. Many oil wells derive their supplies from lenticular beds of sandstone in the midst of impervious shales, and others, as those in the Mexican fields near Tampico, from volcanic tuffs. Asphalt may saturate both sandstones and limestones in such richness as to furnish a natural paving material when crushed, heated and laid. Brines are also yielded by porous strata and supply much of the salt of the world.

C. *Impregnations and Replacements of Naturally Soluble Rocks.*—Ore-deposits of great importance appear in different regions which can only be interpreted as having been formed by the replacement of some or all of a rock with the metallic minerals. The most common rock to yield in this way is limestone, because of its soluble nature, but important cases occur of others composed of silicates. Replacement implies the precipitation of the ore and gangue, molecule by molecule, in the position of the original minerals but without, as in pseudomorphs, the necessary reproduction of crystalline forms. Some waterway must of course introduce the ore-bearing solutions, but it may be slight compared with the great size of the resulting ore-bodies. Lead and zinc ores, often carrying some silver, are those most widely distributed, as they were also the earliest recognized in deposits of this character. More than any other metals their association with limestone is pronounced. The replacements may be found near the supply fissure as in the great zinc deposits near Aachen, or the supply fissures may be obscure as at Leadville, Colorado. While ores occur in the limestone, they are often close along its contact with some relatively impervious stratum, which seems partly to have directed the circulations, partly to have checked or stagnated them, while precipitation took place. With the lead and zinc sulphides, pyrites and chalcopyrite are commonly associated in greater or less degree, the copper increasing locally. All the sulphides are exposed to oxidation above the ground-waters and mining in the upper levels has been often directed against the carbonate and sulphate of lead, or the mingled carbonate and hydrated silicate of zinc.

A non-metallic deposit formed by replacement and of much scientific interest is furnished by sulphur when derived from gypsum, as in the Sicilian and other localities of Europe.

D. *Deposits along Anticlinal Summits and in Synclinal Troughs.*—When strata experience folding they are violently strained at the bends, and, if stiff or brittle like limestone, often crack in limited fissures, which in anticlines open upward and in synclines downward. They thus yield joints in relatively great numbers. Softer rocks, such as shales, are moulded by the strains without fracturing. Very gentle folds seem to have yielded such abundance of cracks in the lead and zinc district of the Upper Mississippi Valley as to cause the so-called "gash veins" which have been worked for many years. The crevices are not all vertical, but often run horizontally and are due to the parting and buckling of individual beds. The resulting ore-bodies are chiefly limited to a single great stratum, and are believed to have been formed by the infiltration of galena, blende and pyrite from overlying formations.

When strata are stiff enough to buckle under violent folding and part so as to produce openings of a crescentic cross-section which afterwards become filled, there result the "saddle-reefs" so remarkably illustrated in the gold veins of Victoria, Australia, and in pitching anticlines of a much larger character in Nova Scotia.

Of far the greatest importance of all the ore-bodies in troughs are the iron ores of the Lake Superior region, now the most productive of all the iron-mining districts. In a series of sedimentary formations, generally of Huronian age, and with associated eruptives, there occur strata consisting of a cherty iron carbonate, which were probably originally marine deposits akin to glauconite. They rest upon relatively impervious rocks, and are often penetrated by basaltic dikes. The entire series has been folded, so that the cherty carbonates, shattered by the strains, have come to rest in troughs of relatively tight, impervious rocks. The descending surface waters have next altered them, have taken the iron into solution, and have redeposited it in the troughs as a slightly hydrated red hematite. The silica has usually been precipitated elsewhere.

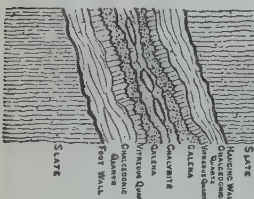
The most important of the non-metallics which occur along anticlinal summits are petroleum and natural gas, but it is true only in a very limited sense that they are introduced in solution. The general cause of the accumulation is, however, the same as that of the metallic minerals, *i.e.* that storage cavities are afforded. In the most productive oil-fields it is the general experience to find the oil and gas impounded in porous rocks, either sandstones or limestones, at the crests of anticlines and beneath impervious shales which do not shatter or crack with gentle folding.

E. *Deposits in Shear-Zones.*—It sometimes happens both in massive rocks and in sediments that strains of compression have been eased by local crushing along comparatively narrow belts without appreciable or measurable displacement of the sides such as would be required by a pronounced fault. The word shear-zone has become quite widely used in recent years as a descriptive term applicable to these cases.

The gold-bearing reefs of the Transvaal present a good illustration. Beds of conglomerate consisting chiefly of quartz and quartzite pebbles have experienced crushing and shattering, and have had their natural porosity much enhanced by these after-effects. Solutions of gold, coming through, have encountered pyrites and have had the gold precipitated upon the pyrites, which is itself often broken and granulated. In other regions shearing has led to sheeting and opening of the rocks by many parallel cracks but almost always with such marked displacement that the next type most correctly describes them. From any point of view the shear-zone is a natural transition to the fault and closely related to it.

F. *Deposits in Faults.*—This type of ore-body was one of the earliest established, and has always figured very prominently in the minds of students of the subject since the first systematic formulations of our knowledge. The dislocation of the earth's crust by faults has furnished either clean-cut fissure or else lines of closely set parallel fractures, whose combined displacement has been comparatively great. The faults go to relatively profound depths and they furnish therefore waterways of extended character, which may reach from regions of heat and pressure in depth to regions of cold and diminishing pressure above; thus from conditions favourable to solution below to conditions favouring precipitation toward the surface. Faults often occur, moreover, in connexion with eruptive outbreaks, and therefore in circumstances especially favourable to ore deposition. From all these reasons it is not surprising that the "true fissure vein" based on a profound fault has been the ideal of the prospector's search in many parts of the world, and has often been his reward. The historic veins of Cornwall and of Saxony are of this type, also the great silver veins of Mexico, the gold veins of California, the great silver-gold deposits of the Comstock lode, and many in South America.

Faulting often leads to great shattering of the country rock, and instead of being a clean-cut open cavity, there results a brecciated belt which may then be cemented by infiltrating ore and gangue. In the midst of this the richer ore occurs as bonanzes or chutes, which are succeeded by leaner stretches. The movement of the walls produces the polished surfaces specifically called "slickensides," parallel to which the ore-chutes often run. The change in the character of the entering solutions from time to time gives a banded character to the deposit, so that from both walls toward the centre corresponding layers succeed one another. At the centre the last layers may meet as interlocking crystals in the familiar comb-in-comb structure or they may leave cavities called "vugs" into which beautiful and perfectly formed crystals project (see fig.). Fault fissures swell and pinch affording wide and narrow places in the resulting ore-body. They often intersect each other and one may throw or heave another, according to the mechanics of faulting as set forth under the article on GEOLOGY.



While fault-fissures have in no way failed in later years to be appreciated by mining geologists, yet they do not hold that predominant place which in the days of more limited experience was theirs. On the contrary, other types such as contact zones, replacements and impregnations are found to be of scarcely inferior importance. Nevertheless the last two, at least, must usually owe to the fault-fissure the waterway which has brought in the solutions.

A very peculiar non-metallic deposit found in fault-fissures and imitating the ordinary veins in all essentials is furnished by the asphaltic minerals, often described as asphaltic coals and known in mineralogy as "grahamite," "albertite," "uintaite," "gilsonite," &c. Petroleums with asphaltic bases have percolated into fault-fissures and have there deposited on evaporation and oxidation their dissolved burdens. The black coaly mineral presents all the geological relations of a fissure vein and is mined like so much ore.

G. *Volcanic Necks.*—A very unusual ore-body is furnished by this type, which is only known in a few instances. In two mines, however, in Colorado, the Bassick and the Bull-Domingo, there occur chimneys of elliptical cross-section filled with rounded boulders, and believed with much reason to be the tubes of small explosive volcanoes. After brief periods of activity they became waterways for uprising heated solutions which filled the interstices with ore.

III. DEPOSITED FROM SUSPENSION.—The ores which result from this process are all formed upon the surface of the earth and through the action of water. They are primarily the result of the weathering of rocks and of the removal of the loose products thus afforded in the ordinary processes of erosion.

A. *Placers.*—Many useful minerals, including some of a metallic character, are very resistant to the agents of decomposition which cause the disintegration of the common rocks. Thus magnetite is a mineral present in a minor capacity in all eruptives and in fairly large percentage in many of the basic types. It is proof against protracted exposure to natural reagents, and it is heavy. Becoming freed by the disintegration of the containing rock it is mingled with the transported materials of running streams, and settles with other heavy minerals wherever the current slackens to a sufficient degree. Concentration may thus ensue and beds of black sand result. If again deposits of loose sand containing more or less magnetite are exposed to the surf of the ocean, or even to the waves of lakes, a similar sorting action takes place on the beach. The magnetite remains behind while the undertow removes the lighter materials. Iron sands of either of these varieties are usually too rich in titanium to be of commercial value, but with the magnetite may be gold or platinum in sufficient amount to be of value.

While magnetite is the commonest of the ores to be found in placers, gold is the metal which usually gives them value. Wherever systems of drainage have eroded gold-bearing rocks, the gold has passed into the streams with the other detrital materials, and, even though in very fine flakes, being yet very heavy has sunk to the bottom in the slackened water and has there enriched the gravel. The gold tends to work its way through the gravels even to the bed-rock, or to some bed of interstratified and impervious clay, and there to be relatively rich. It favours also the insides of bends and the heads of quiet reaches. When a small tributary stream joins a larger one and is both checked itself and checks the current of the large one, the gold, as in the Klondike, tends to settle in relatively great abundance.

Pot-holes, strangely enough, or related rock-cavities, often fail to yield the nuggets, apparently because the swirl of the water and grit has ground them to impalpable powder. The particles have then been washed elsewhere.

When the gold-bearing gravels are panned down a small residue is obtained of all the heavy minerals in the gravel. Magnetite is the commonest and gives the technical name of "black sand" to the concentrate. With it, however, there are almost always found garnet and other less familiar minerals. If the stream valley has been hunted over by sportsmen with shot-guns or rifles, the lost shot and bullets are commonly caught in the pan. Even diamonds have been rarely noted and they may, indeed, be specially sought in gravels.

Along sea-beaches where great beds of auriferous gravel have been attacked by the surf, concentrated bars carrying nuggets and flakes of gold in workable quantity have not infrequently resulted. Cape Nome, Alaska, is perhaps the most productive of all. The gold in the beach-placers is usually worn by the constant attrition into extremely fine particles, and the flakes or colours are more difficult to save than in the case of stream-placers.

In some regions of gold-bearing rocks, as in the south-eastern United States, the products of superficial decay of rocks may remain *in situ* and be sufficiently charged with gold to be washed for the yellow metal. They are different from the usual placer deposit although hydraulicked in the same way. They might be properly considered residual deposits under the next head.

Auriferous stream-gravels of ancient and long-abandoned systems of drainage may remain beneath lava flows or later sedimentary accumulations and be the objects of underground mining. Both in Australia, where they are called "deep leads," and in California, where they are called "buried channels" or "deep gravels," they have been for many years the objects of mining. In California the bed-rock is usually slate or schist and a series of technical terms have resulted descriptive of the rich streaks. The bed-rock is called the rim-rock; the pay-streaks which appear on its sides, bench-gravels, and the lowest one the channel-gravel. Tunnels are often very skilfully driven through the rim-rock to strike the channel-gravel and at the same time preserve the proper slope for drainage and extraction. The buried channels in California have proved of much scientific interest from the remains of prehistoric man, skulls, mortars and pestles which they have yielded.

Among the non-metallic minerals sought from placers, phosphates for fertilizers hold a position of great importance.

B. *Residual Deposits.*—As contrasted with the placers whose materials are derived by transport from a distance, we sometimes find heavy and resistant minerals, once contained in the rock but freed by the process of decay and disintegration. The lighter loose materials are washed away and deposited elsewhere. The heavy remain behind in a concentrated condition. Iron ores of this character are known, and chromite is set free in the same way by the decomposition of serpentine.

In the decay of ferruginous rocks like limestones the iron may be changed to the insoluble ferric hydrate, brown hematite, and remain as veinlets and crusts throughout a mantle of clay. The brown hematite may be freed by artificial washing and used as an iron ore.

IV. CARBONACEOUS DEPOSITS FROM VEGETATION.—Far the most important of the non-metallic minerals are those composing the coal series. They yield entire strata analogous to other sedimentary rocks, but in most cases from vegetation which has grown *in situ*. They are found in all stages from nearly carbonized leaves and woody tissue in peat, through much more altered materials in lignite and bituminous coal to extremes in anthracite and graphite. The prime necessity for their preservation from decay is furnished by water, in or near which they must grow, and beneath which they must be deposited, so that oxidation may be retarded. In instances they have been heaped together by rivers, especially when at flood. The method of origin is fully discussed under COAL and under

Mining, but it may be remarked here that once formed they undergo all the foldings, faultings and disturbances which have affected the sedimentary rocks of other kinds.

Bibliography.—The following are general works on the deposits of the useful minerals, in addition to Posepny's volume already mentioned: In English—J. A. Phillips, revised by Henry Louis, *Treatise on Ore-Deposits* (London, 1896); J. F. Kemp, *Ore-Deposits of the United States and Canada* (New York, 1900); Prime's translation of Von Cotta's *Ore-Deposits* (New York, 1870); H. Ries, *Economic Geology of the United States* (New York, 1906); W. H. Weed's translation of Beck's *The Nature of Ore-Deposits* (New York, 1905); *Genesis of Ore-Deposits* (American Institute of Mining Engineers, 1901); G. P. Merrill, *The Non-Metallic Minerals* (New York, 1904). MINERALOGY, the science which describes and classifies the different kinds of mineral matter constituting the material of the earth's crust and of those extra-terrestrial bodies called meteorites. The study of minerals is thus a branch of natural history, but one in which certain of the exact sciences find an application. The determination of the composition and constitution of minerals is a chemical problem; their optical and other physical properties are determined according to the principles of physics; the study of their crystalline form and structure belongs to crystallography; their modes of occurrence, origins, associations and changes come within the province of geology and petrology; while a consideration of the localities at which they are found requires some acquaintance with geography. Finally, there is the economic side, dealing with the mining and application of useful minerals, the extraction of metals from their ores, and the uses of minerals for building, decoration and jewelry.

In this article we shall treat only of the general characters of minerals; their special characters will be found in the articles on the individual minerals.

After a brief historical sketch the subject will be treated under the following headings:—

I. Characters of Minerals.
    1. Morphological Characters.
        a. Crystalline Form.
        b. State of Aggregation: Structure.
    2. Physical Characters.
        a. Optical Characters (Colour, &c.).
        b. Magnetic, Electrical and Thermal Characters.
        c. Characters depending on Cohesion (Hardness, &c.).
        d. Specific Gravity.
        e. Touch, Taste and Smell.
    3. Chemical Characters.
        Synthesis of Minerals.
II. Occurrence and Origin of Minerals.
    Alteration of Minerals: Pseudomorphs.
III. Nomenclature and Classification of Minerals.

History.—Owing to their numerous applications for useful and decorative purposes, minerals have attracted the attention of mankind from the earliest times. The stone and bronze implements of prehistoric man and many of his personal ornaments and charms were directly or indirectly of mineral origin. The oldest existing treatise on minerals is that written about 315 B.C. by Theophrastus (περὶ τῶν λίθων—*On Stones*, English version by John Hill, 1746), of which only a portion is now in existence. Minerals were then classed as metals, stones and earths. The last five books of Pliny's *Historia naturalis*, written about A.D. 77, treat of metals, ores, stones and gems. Some of the Arabian philosophers devoted themselves to the study of minerals, and about 1262 Albertus Magnus wrote his *De mineralibus*. In the 16th century Georgius Agricola published several large volumes, dealing more especially with the mining and metallurgy of metalliferous minerals, in which more exact descriptions were given of the external characters: he mentioned several minerals by names (*e.g.* blende, fluor, quartz) which are now in common use. About the same period there appeared the systematic treatise on minerals of K. Gesner (1565), and that on precious stones by Anselm Boethius de Boodt (1609). The remarkable researches of Erasmus Bartholinus on Iceland-spar were published in 1669, and J. F. Henckel's *Pyritologia* in 1725. Later came the *Systema naturae* of C. Linnaeus (1735). Although the importance of chemical properties was recognized by the Swedish chemists—J. G. Wallerius (1747) and A. F. Cronstedt (1758)—the external characters of minerals formed the basis of the mixed systems of classification of A. G. Werner (1774) and of other authors, and even as late as the *Natural History System of Mineralogy* of F. Mohs (1820).

It was not until the end of the 18th and beginning of the 19th century, when the foundations of crystallography were laid by Romé de l'Isle and R. J. Haüy, and chemistry had assumed its modern phase, that any real advance was made in scientific mineralogy. It was then recognized that chemical composition and crystalline form were characters of the first importance, and that external (natural history) characters were often more or less accidental. During this period numerous mineral substances were analysed by Scheele, Klaproth, Charles Hatchett, Vauquelin, Kirwan, Berzelius, Rose and other chemists, and many new mineral-species and chemical elements discovered. After W. H. Wollaston's invention of the reflecting goniometer in 1809, exact measurements of the crystalline forms of many minerals were made. The principles of isomorphism and dimorphism enunciated by E. Mitscherlich in 1819 and 1821 respectively cleared up many difficulties encountered in the definition of mineral-species. About the same time also the discovery by E. L. Malus of the polarization of light gave an impetus to the optical examination, by Sir David Brewster and others, of natural crystals. Later, the investigation of rocks in thin section under the microscope led to the exact determination, particularly by A. Des Cloizeaux (1867), of the optical constants of rock-forming minerals.

For a detailed account of the history of mineralogy (including crystallography), see F. von Kobell, *Geschichte der Mineralogie von 1650–1860* (München, 1864). The recent history of mineral-species may be well traced in the six editions of J. D. Dana's *System of Mineralogy* (1837–1892).

I.—Characters of Minerals.

A distinction is to be made between essential and non-essential characters. Essential characters are those relating to chemical composition, crystalline form, crystallo-physical properties and specific gravity; these are identical, or vary only within certain defined limits, in all specimens of the same mineral-species. Non-essential characters—such as colour, lustre, hardness, form and structure of aggregates—depend largely on the presence of impurities, or on the state of aggregation of imperfectly formed crystalline individuals. In an absolutely pure and perfectly developed crystal all the characters may be said to be essential, but such crystals are of exceptional occurrence in nature, and certain of the characters are subject to modification under different conditions of growth. For example: a well-formed crystal of haematite ("specular iron ore"), with its smooth black faces and brilliant metallic lustre, is strikingly different in appearance from a piece of massive haematite ("red iron ore"), which is dull and earthy and bright red in colour; the former is so hard that it can only with difficulty be scratched with a knife, while the latter is quite soft and soils the fingers. Both specimens will, however, be found on analysis to have the same chemical composition (Fe_2O_3), the same crystalline structure (as determined by the optical characters under the microscope in the case of the massive variety), and very nearly the same specific gravity (especially if this be determined upon finely powdered material, the effect of cavities being thus eliminated). The essential characters being identical, the difference between the two specimens lies in the state of aggregation of the material: with "specular iron ore" we have a single crystal, while with the "red iron ore" we are dealing with a confused aggregate of minute crystalline individuals, which have interfered with each other's growth to such an extent that no crystal-faces have been developed. Such differences do not therefore depend on the nature of the material, but only on the conditions which prevailed during its growth. (See *e.g.* QUARTZ and CALCITE.)

In the following enumeration of the more salient characters of minerals it is to be noted that many of the terms used for non-essential characters are purely descriptive and have no exact definition; on the other hand, essential characters can be expressed numerically and are therefore perfectly definite.

1. *Morphological Characters.*

a. Crystalline Form.—This most important character of minerals can, of course, be determined only when the material available is in the form of crystals (*i.e.* crystallized), which is not always the case. Massive aggregates of crystalline material are of much more frequent occurrence; when small fragments or thin sections of such material are transparent, the crystalline symmetry may be determined, within certain limits, by the help of the optical characters (see below). External crystalline form must not, however, be considered alone apart from all other characters, for crystals of substances quite different chemically, *e.g.* silver iodide, zinc oxide and zinc sulphide, are sometimes almost identical in crystalline form; further, in groups of isomorphously related minerals the degree of symmetry will usually be the same and the angles vary only slightly, and unless the crystals are perfectly developed and suitable for exact goniometric measurement no crystallographic distinction can be made between two such species.

All the six systems of crystals and most of the thirty-two symmetry-classes are represented amongst minerals (see CRYSTALLOGRAPHY). Crystals of the same mineral-species may differ very widely in general form or habit; *e.g.* crystals of calcite (*q.v.*) may be rhombohedral, prismatic, scalenohedral or tabular in habit. Other descriptive terms of the habit of crystals are pyramidal, acicular or needle-shaped (from the Lat. *acicula*, a needle), capillary or hair-like (from the Lat. *capillus*, hair), &c.; and these peculiarities of habit may sometimes be characteristic of certain minerals. Sometimes also there are characteristic kinds of groupings of crystals: thus parallel, divergent or radiating (*e.g.* scolecite), rosette-shaped (*e.g.* haematite—*Eisenrosen*), reticulated (*e.g.* rutile), or matted. The faces of natural crystals may be smooth, rough, striated, curved or drusy,[1] *i.e.* studded with small crystal faces and angles.

b. State of Aggregation: Structure.—According to the particular state of aggregation of a number of imperfectly developed crystals, which have grown together, various kinds of structure may be presented even by the same mineral species. The descriptive terms applied to these structures are almost self-explanatory: thus the structure may be granular (*e.g.* marble), fibrous (asbestos), radio-fibrous or stellated (wavellite), columnar (beryl), laminar or lamellar (talc), bladed (cyanite), &c., according to the relative shape and sizes of the individual crystals composing the aggregate. When the constituent crystals are invisible to the unaided eye the material is described as compact; incoherent aggregates are powdery or earthy. Minerals which are really amorphous, *i.e.* without any crystalline structure, are comparatively few in number (*e.g.* opal); many which are apparently amorphous are really microcrystalline (*e.g.* turquoise). The term massive is often used loosely for a crystalline mineral not showing crystal-faces. Crystal-aggregates often assume more or less accidental and imitative external forms to which the following descriptive terms are applied: dendritic or arborescent (*e.g.* copper, pyrolusite), mossy (copper), leafy (gold), wiry or filiform (silver), capillary (millerite), coralloidal (aragonite), globular (aragonite, with concentric structure; wavellite, with radiated structure), mamillary or with breast-like protuberances (arsenic), nodular (malachite), warty (menilite), botryoidal or resembling a bunch of grapes (from *βότρυς*, a bunch of grapes) (dolomite), reniform or kidney-shaped (menilite), amygdaloidal or almond-shaped (agate), stalactitic (calcite, chalcedony), &c.

2. *Physical Characters.*

a. Optical Characters.—The action of crystallized matter on transmitted light is a character of the highest importance in mineralogy. Even when the substance is opaque in large masses, it may be sufficiently transparent when in small splinters or in thin sections for the determination of the optical characters. The refractive indices, strength of the double refraction, optic axial angle, extinction angles on certain faces, &c., are characters capable of exact measurement and numerical expression, and are constant for each mineral-species. (See CRYSTALLOGRAPHY.)

In their "diaphaneity," or degree of transparency, minerals differ very widely even in the same species. Some, such as metals and most metallic sulphides are always opaque; while others may vary in different specimens from perfect transparency to perfect opacity (in the latter case, however, minute fragments will, as a rule, still be transparent). A good example of this is afforded by the varieties of quartz: rock-crystal is water-clear, chalcedony is translucent, and jasper opaque.

The "colour" of minerals is the character which first arrests attention; but being a character which may vary almost indefinitely in one and the same kind of mineral, it affords a typical example of a non-essential character. Thus, fluor-spar and quartz, when in well-formed and chemically pure crystals, are quite colourless and transparent; but it would be easy to collect a series of each of these minerals in which almost every shade of colour is represented. Crystals of fluor-spar of an emerald-green, purple, golden-yellow, bright pink or other colour are at first sight very different in appearance, and yet the difference is due solely to the presence of traces of colouring matters so small in amount that their exact nature is difficult or impossible to determine. The value of diamond, corundum and other gemstones depends largely on these accidental differences in colour. Such substances, which are essentially colourless and owe their colour to the presence of colouring matter as an impurity, are said to be "allochromatic": any colour they may possess is non-essential. In some other substances, known as "idiochromatic," the colour is a definite and essential character; for example, the yellow colour of gold, the red of cinnabar, &c.; but even here, owing to differences in the state of aggregation and the presence of various impurities, they may be wide variations in colour. Colour is thus a character of little determinative value, especially in minerals which are allochromatic; but it is sometimes a useful guide when taken in conjunction with other characters. An elaborate list of colour-names for descriptive use was drawn up by A. G. Werner in 1774.

An important character of transparent crystals is that of unequal absorption in different directions; so that light will, as a rule, be differently coloured according to the direction in which it has travelled through the crystal: this is known as dichroism or pleochroism (see CRYSTALLOGRAPHY). Certain minerals (*e.g.* zircon, almandine and those containing cerium) when examined with a spectroscope by transmitted light exhibit characteristic absorption spectra.

The colours of minerals may also be due to the interference of rays of white light at the surfaces of thin crevices or minute inclusions, either tabular or fibrous in form, in the mineral; for example, the play of colours of opal; the change of colours of labradorite; the bands of rainbow colours (Newton's rings) seen along cleavage cracks and irregular internal fractures (*e.g.* in quartz); the iridescent tarnish due to a superficial film of a decomposition product (*e.g.* "peacock copper ore"); or the bluish opalescence of moon-stone and cat's-eye.

The true colour of a mineral is best revealed by its "streak," *i.e.* the colour of its powder. This is obtained by scratching the mineral, or by crushing a fragment of it on a sheet of white paper, or rubbing it upon unglazed porcelain. The streak of allochromatic minerals is white, while that of idiochromatic minerals is coloured and is often of determinative value. Ores of iron may, for example, generally be distinguished by their streaks: that of magnetite being black; haematite, blood-red;

---

[1] This is from a German word, *druse*, originally meaning "brush," and applied by miners to hollow stones, lined with minute projecting crystals.

limonite, yellow; and chalybite, white. The streak of a mineral may be either shining (*e.g.* argentite) or dull.

Another character depending on light is that of lustre, which is often very characteristic in certain minerals, though it may be considerably modified by the state of aggregation. For example, the usual adamantine lustre of diamond is not exhibited by the compact aggregate known as carbonado; while earthy masses of any mineral will be devoid of lustre. Descriptive terms applied to the kinds of lustre are: metallic (*e.g.* pyrites), adamantine (diamond), vitreous (quartz), resinous (pyromorphite), greasy (elaeolite), waxy (chalcedony), pearly (talc, heulandite and other minerals with a perfect cleavage), silky (satin-spar), &c. The degrees of intensity of lustre are described as splendent, shining, glistening, glimmering and dull, and depend usually on the smoothness of the crystal-faces.

The phenomena of phosphorescence (*q.v.*), fluorescence (*q.v.*) and radio-activity (*q.v.*) are strikingly exhibited by some minerals. (See FLUOR-SPAR, DIAMOND, &c.)

b. Magnetic, Electrical and Thermal Characters.—These, as far as related to crystalline form, are discussed under crystallography (*q.v.*). Magnetite ("lode-stone") is the only mineral which is strongly magnetic with polarity; a few others, such as pyrrhotite and native platinum, possess this character to a much less degree. Many minerals are, however, attracted by the pole of a strong electro-magnet, while a few (diamagnetic) are repelled.

Most minerals with a metallic lustre are good conductors of heat and electricity; others are bad conductors. For example, graphite is a good conductor, while diamond is a bad conductor. Non-conductors of electricity become electrified by friction, some positively (*e.g.* quartz and topaz), others negatively (*e.g.* sulphur and amber). The length of time during which different gem-stones retain their charge of frictional electricity was made use of by R. J. Haüy as a determinative character. For the pyro-electrical and thermo-electrical characters of crystals see CRYSTALLOGRAPHY. Some minerals—for example, salt, sylvite and blende—are highly diathermanous, *i.e.* transparent for heat-rays.

The specific heat and melting point of minerals are essential characters capable of exact measurement and numerical expression, but they are not often made use of. Different minerals differ widely in their "fusibility": the following scale of fusibility was proposed by F. von Kobell:—

1. Stibnite	(525° C.)
2. Natrolite	(965° C.)
3. Almandine	(1265° C.)
4. Actinolite	(1296° C.)
5. Orthoclase	(1175° C.)
6. Bronzite	(1300° C.)
7. Quartz	(1430° C.)

The melting points given above in parentheses were determined by J. Joly. Stibnite readily fuses to a globule in a candle-flame, while quartz is infusible even on the thinnest edges before the ordinary blowpipe.

c. Characters depending on Cohesion.—Some minerals (*e.g.* a sheet of mica) are highly elastic, springing back to their original shape after being bent. Others (*e.g.* talc) may be readily bent, but do not return to their original form when released; these are said to be pliable or flexible. Sectile minerals (*e.g.* chlorargyrite) may be cut with a knife without being fractured: related characters are malleability (*e.g.* argentite) and ductility (*e.g.* silver). The tenacity, or degree of frangibility of different minerals varies widely: they may be brittle, tough, soft or friable. The fractured surface produced when a mineral is broken is called the "fracture," and the kind of fracture is often of determinative value; descriptive terms are: conchoidal (*e.g.* quartz, which may often be recognized by its glassy conchoidal fracture), sub-conchoidal, uneven, even, splintery (*e.g.* jade), hackly or with short sharp points (*e.g.* copper), &c.

In many cases when a crystallized mineral is broken it separates in certain definite directions along plane surfaces. This property of "cleavage" (see CRYSTALLOGRAPHY) is an important essential character of minerals, and one which is often of considerable assistance in their recognition. For example, calcite, with its three directions of perfect cleavage parallel to the faces of a rhombohedron, may always be readily distinguished from aragonite or quartz; or again, the perfect cubical cleavage of galena renders this mineral always easy of recognition.

"Hardness," or the resistance which a substance offers to being scratched by a harder body, is an important character of minerals, and being a test readily applied it is frequently made use of. It must, however, be remembered that the hardness of an incoherent or earthy aggregate of small crystals will be very different from that of a single crystal. A comparative "scale of hardness" was devised by F. Mohs in 1820 for the purpose of giving a numerical statement of the hardness of minerals.

Mohs's Scale of Hardness.

1. Talc.
2. Gypsum.
3. Calcite.
4. Fluor-spar.
5. Apatite.
6. Orthoclase.
7. Quartz.
8. Topaz.
9. Corundum.
10. Diamond.

These minerals, arbitrarily selected for standards, are successively harder from talc the softest, to diamond the hardest of all minerals: a piece of talc is readily scratched by gypsum, and so on throughout the scale. A mineral which is capable of scratching calcite and itself be as easily scratched by fluor-spar is said to have a hardness of $3\frac{1}{2}$. Some care is required to avoid error in the determination of hardness: it is best to select a smooth crystal-face, cleavage-surface or fracture on which to rub a sharp corner of the scratching mineral; the powder should be wiped off and the surface examined with a lens to see if a scratch has really been produced or only powder rubbed off the corner of the mineral with which the scratching was attempted. With a little practice a fair idea of the hardness of a mineral may be obtained with the use of a knife or file, which will scratch all minerals with a hardness of 6 or less. Thus iron-pyrites (H. = $6\frac{1}{2}$) and copper-pyrites (H. = $3\frac{1}{2}$), apatite (H. = 5) and beryl (H. = $7\frac{1}{2}$), or gem-stones and their paste imitations may be readily distinguished by this test. Talc and gypsum can be readily scratched with the finger-nail.

Planes of parting, etching figures, pressure- and percussion-figures are sometimes characters of importance in describing and distinguishing minerals. (See CRYSTALLOGRAPHY.)

d. Specific Gravity.—The density or specific gravity of minerals is an essential character of considerable determinative value. In minerals of constant composition it has a definite value, but in isomorphous groups it varies with the composition: it also, of course, varies with the purity of the material. It is a character which has the advantage of numerical expression: minerals range in specific gravity from 1·01 for copalite to 22·84 for iridium. The exact determination of the specific gravity of minerals is therefore a matter of some importance. Three methods are in common use, viz. hydrostatic weighing, the pycnometer, and the use of heavy liquids. The first two methods are only applicable when a weighable amount of pure material can be selected or picked out; this is, however, generally a laborious operation, since impurities are often present and usually several species of minerals are closely associated, and in selecting material it is often necessary to determine some other character to make certain that only one kind is being selected. For exact determinations the pycnometer method is usually to be recommended, using for material the pure fragments which have been selected for quantitative chemical analysis. With a single pure crystal or a faceted gem-stone the method of hydrostatic weighing is usually applicable, providing the stone is not too small. The most ready method, however, is that afforded by the use of a heavy liquid, and the most convenient liquid for this purpose is methylene iodide. This is a clear, mobile liquid with a specific gravity of 3·33, and by the addition of benzene, drop by drop, the specific gravity may be reduced to any desired amount. With such a liquid the specific gravity of the minutest fragment, the purity of which has previously been scrutinized under the microscope, may be rapidly determined. The liquid is diluted with benzene until the fragment just remains suspended, neither floating nor sinking; the specific gravity of the fragment will then be the same as that of the liquid, and the latter may be determined by hydrostatic weighing or, more conveniently, by means of indicators. Small recognizable crystals of the following minerals may be kept at hand as a set of indicators: gypsum (sp. gr. 2·32), colemanite (2·42), orthoclase (2·56), quartz (2·65), calcite (2·72), aragonite (2·93), rubellite (3·02), apatite (3·20), dioptase (3·32), &c. With a series of tubes containing mixtures of methylene iodide and benzene of different densities and suitable indicators, specific gravities may be rapidly and accurately determined. Values intermediate between those of the indicators may be estimated by a diffusion column of the liquid, or by noting the rate at which the benzene evaporates and the specific gravity of the liquid increases. For use with minerals of specific gravity greater than 3·33 various other heavy liquids have been suggested; the best being thallium silver nitrate ($TlAg(NO_3)_2$), which melts at 75° C. to a clear liquid with a density of 4·8, and is miscible with water.

e. Touch, Taste and Smell.—In their action on the senses of touch, taste and smell a few minerals possess distinctive characters. Talc is unctuous or soapy to the touch; tripolite and trachyte are respectively meagre and harsh. Some porous minerals (*e.g.* clays and hydrophane) adhere to the tongue. Gem-stones may often be distinguished from their glass imitation by the fact that they feel colder, since they are better conductors of heat. Bitumen and clays, when moistened, have a characteristic smell; pyrites and some other sulphides when rubbed emit a sulphurous odour. Minerals which are soluble in water have taste: *e.g.* saline (salt), alkaline (natron), bitter (epsomite), astringent (chalcanthite), &c.

3. *Chemical Characters.*

Chemical composition is the most important character of minerals, and on it all modern systems of classification are based. A mineral-species cannot, however, be defined by chemical composition alone, since many instances are known in which the same chemical element or compound is dimorphous or polymorphous (see CRYSTALLOGRAPHY). Thus both the minerals diamond and graphite consist of the element carbon; both calcite and aragonite consist of calcium carbonate; and rutile, anatase and brookite consist of titanium dioxide. In such cases a knowledge of some other essential character, preferably the crystalline form, is necessary, before the mineral can be determined.

All the known chemical elements have been found in minerals; and of many of them minerals are the only source. On the other hand, nitrogen, which is frequently present in organic substances, is rare in minerals; carbon has a wide distribution in mineral carbonates. It is estimated that the minerals of the earth's crust consist of about 47% by weight of oxygen, 27 of silicon and 8 of aluminium; silicates, and especially aluminosilicates, therefore predominate, these being the more important rock-forming minerals.

The chemical composition of minerals is determined by the ordinary methods of analytical chemistry. Since, however, minerals of different kinds usually occur intimately associated, it is often a matter of some difficulty to select a sufficiency of pure material for analysis. For this reason the exact composition and the empirical formulae of several minerals, particularly amongst the silicates, still remain doubtful. There are even cases on record in which the chemical composition and the crystalline form have been determined on different materials in the belief that they were the same. Whenever possible, therefore, the chemical analysis should be made on small pure crystals which have been previously determined crystallographically. For the qualitative chemical examination of minerals, when only a small amount of material is available, the methods of blowpipe analysis and microchemical analysis are often convenient. (See G. J. Brush, *Manual of Determinative Mineralogy*, 16th ed., by S. L. Penfield, New York, 1903; H. Behrens, *Manual of Microchemical Analysis*, London, 1894.)

The principle of isomorphism (see CRYSTALLOGRAPHY) is of the highest importance in mineralogy, and on it the classification of minerals largely depends. In some minerals (*e.g.* quartz) isomorphous or vicarious replacement is not known to occur; but in the majority of minerals one or other of the predominating elements (generally the base, rarely that of the acid radicle) may be isomorphously replaced by equivalent amounts of other chemically-related elements. In some isomorphous groups of minerals replacement takes place to only a limited extent, and the element which is partly replaced always predominates; while in other groups the replacement may be indefinite in extent, and between the ends of the series the different members may vary indefinitely in composition, with no sharp demarcation between species. Thus in the group of rhombohedral carbonates the different species are usually sharply defined. In well-formed crystals of calcite the calcium is replaced by only small amounts of magnesium, iron, lead, &c.; in chalybite, however, iron is often more largely replaced by calcium, magnesium, manganese, &c., and the "brown spars" are not always readily distinguishable. In the dimorphous group of orthorhombic carbonates isomorphous replacement is less frequent, and the different species (aragonite, cerussite, &c.) are quite sharply defined. In other groups of minerals, particularly amongst the silicates, isomorphous replacement of the basic elements is so general that the several members of the series vary almost indefinitely in chemical composition, and will scarcely be the same for any two specimens, though it may be reduced to the same type of formula. For example, the formula of all varieties of garnet may be expressed generally as $R''_3R'''_2(SiO_4)_3$, where $R'' = $ Ca, Mg, Fe, Mn, and $R''' = $ Al, Fe, Mn, Cr, Ti. Tourmaline affords another good example. In the plagioclase felspars (see PLAGIOCLASE) we have an example of the isomorphous mixing of two end-members, albite ($NaAlSi_3O_8$) and anorthite ($CaAl_2(SiO_4)_2$) in all proportions and with no sharp line between the several sub-species. In some other similar cases the end-members of the series are purely hypothetical: *e.g.* in the scapolite group (mixtures of $Ca_4Al_6Si_6O_{25}$ and $Na_4Al_3Si_9O_{24}Cl$) and in the micas and chlorites. In such instances, where the formulae of the two end-members differ in type, "mass effect" may have some influence on the isomorphism.

In addition to isomorphous series, there are amongst minerals several instances of double salts, which contain the same constituents as the members of isomorphous series: *e.g.* dolomite (*q.v.*) and barytocalcite (*q.v.*).

The manner in which water enters into the composition of minerals is often difficult to determine. In some cases, *e.g.* in the zeolites (*q.v.*), it is readily expelled at a low temperature, even at the ordinary temperature over sulphuric acid, and may be reabsorbed from a moist atmosphere or replaced by some other substances: it is then regarded as "water of crystallization." In other cases, when expelled only at a higher temperature, it is to be regarded as "water of constitution," forming either a basic salt (*e.g.* malachite, $Cu(OH)_2CO_3$) or an acid salt (*e.g.* dioptase, H_2CuSiO_4, and mica, *q.v.*). When present as hydroxyl it is often isomorphously replaced by fluorine (*e.g.* topaz, $[Al(F,OH)]_2SiO_4$). Sometimes the water is partly water of crystallization and partly water of constitution.

As to the actual chemical constitution of minerals the little that is at present known is mainly speculative. Dimorphous minerals, which have the same empirical formula may be expected to differ in constitution; and experiments have been made, for example on pyrites and marcasite, with the object of discovering a difference, but the conclusions of various investigators are not in agreement. More promising results have been obtained (by F. W. Clarke and others) by the action of various reagents on silicates, particularly on the more readily decomposed zeolites, and several substitution-derivatives have been prepared.

Synthesis of Minerals.—The production of minerals by artificial means is a branch of chemical mineralogy which has been pursued with considerable success, especially by French chemists. Most minerals have been obtained artificially in a crystallized condition, and many related compounds, not as yet found in nature, have also been prepared. Crystals of artificially prepared minerals, though usually quite small in size, possess all the essential characters of natural crystals, differing from these only in origin. The following are the principles of some of the methods which have been used: simple sublimation (*e.g.* arsenolite); interaction of gases (*e.g.* haematite, from steam and ferric chloride; cassiterite, from steam and stannic chloride or fluoride); action of gases on liquids and solids; slow cooling of fused masses, either with or without the presence of *agents minéralisateurs* (*e.g.* minerals in furnace slags); from aqueous solution sometimes at a high temperature and under pressure (*e.g.*, quartz); electrolysis; or even by subjecting dry amorphous material to enormous pressure. The chemical reactions by which various minerals have been obtained are often of considerable help in speculating as to their mode of origin in nature, though it must be born in mind that the same mineral may have been formed, both naturally and artificially, by more methods than one. In this direction important results have been obtained experimentally by J. H. van't Hoff and his pupils on the formation of oceanic salt deposits, and by J. H. L. Vogt with slags. Many minerals used as gem-stones have been prepared artificially, *e.g.* diamond and ruby (see GEMS: *Artificial*).

II.—Occurrence and Origin of Minerals.

While some minerals are of rare and sporadic occurrence in rock-cavities and mineral-veins, others are widely distributed as important constituents of rocks. The same mineral species may have several distinct modes of occurrence and origin, and be associated with different minerals in each case; facts which are well illustrated by quartz (*q.v.*).

Minerals of Igneous Rocks.—The rock-forming minerals of primary origin in igneous rocks have crystallized out from the magma, or fused silicate-mass, which on consolidation gave rise to the rock-mass. Magmas sometimes contain a considerable amount of water and are then in a state of aqueo-igneous fusion, rather than of dry fusion: in such cases very coarsely crystalline rocks (pegmatites) often result, and under these conditions minerals of many kinds are formed as well-developed crystals. Those minerals which are present in large amount in igneous rocks are distinguished as essential constituents, since it is on these that the classification of igneous rocks is largely based: the most important are quartz, felspars, pyroxenes, amphiboles, micas and olivines. Felspars of different composition are present in almost all kinds of igneous rocks, while quartz and olivine are characteristic of acid (*e.g.* granite, rhyolite) and basic (*e.g.* basalt, peridotite) rocks respectively. When the magma contains alkalies in relatively large amount the "felspathoid" minerals, nepheline and leucite, are formed (*e.g.* in nepheline-syenite, leucite-basalt, &c.). Other minerals occurring as primary constituents, but only in small amounts, are distinguished as accessory; thus small crystals of magnetite, apatite, zircon, &c., are of frequent occurrence disseminated in igneous rocks (see PETROLOGY). Sometimes these accessory constituents are concentrated by magmatic differentiation, important ore-deposits sometimes resulting in this manner (*e.g.* of chromite, or nickel-bearing pyrrhotite). The alteration of igneous rocks by weathering and other processes results in the alteration of some or all of the primary minerals with the production of others, which are spoken of as secondary minerals: thus felspars are often partly or wholly altered to kaolin, olivine to serpentine, pyroxene and mica to epidote, chlorite, &c.

Minerals are also formed by the vapours given off by igneous magmas. The gases emitted by volcanoes and solfataras may deposit directly by sublimation, or by their chemical interaction, such minerals as sulphur, sal-ammoniac, haematite, which occur, for instance, as incrustations on Vesuvian lava: the boric acid of the Tuscan lagoons has also originated in this way. The effects produced by the exhalations of deep-seated magmas are more complex in character, since the vapours, being more confined, have more opportunity of acting chemically not only on the surrounding rocks but also on the igneous rock-mass itself before its final consolidation. A good example of the "pneumatolytic" action produced by the vapours from a mass of granitic magma is afforded by veins of tin-ore, in which the ore (cassiterite) is associated with minerals containing boron and fluorine, such as topaz, tourmaline, lepidolite, fluor-apatite and fluor-spar. The production of such minerals may be accounted for by assuming the presence of stannic fluoride in the vapours, which by reacting on water vapour would deposit cassiterite with the liberation of hydrofluoric acid, and this would again react on other minerals. The topaz and tourmaline crystals often found in the cavities of granites and pegmatites have doubtless been formed in this manner. In a similar way the exhalations of basic magmas have given rise to chlor-apatite with associated sphene and ilmenite, as, for example, in the extensive apatite veins in connexion with gabbro in southern Norway.

Minerals of Metamorphic Rocks.—By the baking action of a deep-seated igneous mass on the surrounding rocks or on included rock-fragments, various new minerals are developed. By this process of thermal or contact-metamorphism well-crystallized examples of many minerals have often been formed; *e.g.* in calcareous rocks (limestones), especially those containing some magnesia and silica, vesuvianite, garnet, diopside, tremolite, wollastonite, &c., are developed; in argillaceous rocks (slates), chiastolite and staurolite are characteristic products; and in arenaceous rocks (sandstones), cordierite and sillimanite often result. The effects of pressure (dynamo-metamorphism) on rocks of various kinds, especially those of igneous origin, also result in the production of new minerals: *e.g.* pyroxene is transformed to amphibole, orthoclase to muscovite, plagioclase to zoisite, olivine to tremolite, &c. In gneisses and crystalline schists, quartz, felspar, mica, talc, amphibole, &c. are important constituents.

Minerals of Sedimentary Rocks.—By the weathering and disintegration of igneous and metamorphic rocks the various minerals set free and the products of decomposition of others supply the material of sedimentary rocks; thus sandstones consist largely of quartz, shales of kaolin and other clay minerals. Those minerals (*e.g.* gem-stones and gold) which resist the action of weathering processes are found as water-worn pebbles and grains in detrital deposits. Other sedimentary rocks consist of minerals deposited from solution either by chemical or organic agencies, from sea-water, lakes or springs: *e.g.* the calcite of limestones, deposits of bog-iron-ore (limonite), gypsum, rock-salt, &c.

Minerals Segregated in Veins and Rock-cavities.—Water percolating through rock-masses takes up mineral matter in solution, and the solutions so formed may further react on the minerals composing the rocks. Such solutions will deposit some of their dissolved material in rock-cavities with the production of various minerals. For instance, the amygdaloidal cavities of basic volcanic rocks (*e.g.* basalt, melaphyre), especially when the rocks are somewhat weathered, are frequently partly or completely filled with agate or beautifully crystallized zeolites, calcite, &c. The crevices and joint-planes of limestone become in this way coated with crystals of calcite, and those of siliceous rocks with quartz, giving rise to the abundantly occurring quartz-veins. In sedimentary rocks, pyrites, flint and other minerals become segregated round a nucleus of organic matter. The beautiful crystal-lined crevices in the crystalline rocks of the Alps have much the same origin, and so have the various types of ore-deposits, including metalliferous veins or lodes. In the latter cases, however, the solutions are no doubt sometimes of deep-seated origin and often connected with igneous and metamorphic processes. Metalliferous veins are storehouses of crystallized minerals of almost every kind, some being the ores themselves and others, such as quartz, calcite, barytes, fluor-spar, being gangue minerals. By the weathering of the metallic minerals of mineral-veins numerous other finely crystallized minerals result: for example, in the upper oxidized portion of veins of lead-ore (galena), crystals of anglesite, cerussite and pyromorphite are often met with; in veins of copper-ore the alteration of chalcopyrite gives rise to malachite, chessylite and cuprite.

Alteration of Minerals: Pseudomorphs.—Crystals which have been formed under one set of conditions of temperature and pressure and in the presence of certain solutions, will in many cases be unstable under another set of conditions. The crystals may then be corroded or even completely redissolved, or the substance may undergo a chemical or physical change and give rise to the formation of other minerals which are stable under the new conditions. The results of such changes and alterations of minerals are very frequently to be observed in nature, and several instances have already been cited in the preceding section. A good example of the secondary products which may result by the decomposition of a mineral is afforded by pyrites (FeS_2), of which two types of alteration may be distinguished. By oxidation in the presence of pure water it gives rise to ferrous sulphate (melanterite), free sulphur and sulphuric acid; the melanterite by further alteration gives various basic ferric sulphates (copiapite, &c.); and the sulphuric acid by acting on surrounding rocks (limestone, clay, &c.) gives rise to the formation of gypsum, aluminite and other sulphates. By the action of water containing oxygen and calcium carbonate in solution, pyrites suffers another kind of alteration: the sulphur is carried away in solution as gypsum and the iron is left behind as a ferric hydroxide (limonite) which preserves the original form of the crystals. We have then a pseudomorph (from ψευδής, false and μορφή, form) of limonite after pyrites; *i.e.* limonite with the external form of a crystal of pyrites.

Pseudomorphs are frequently met with in nature, and they are of considerable importance in studying the changes which minerals undergo. Several kinds of pseudomorphs are to be distinguished. When the alteration has involved no change in chemical composition of the material, but only in the internal crystalline structure and physical properties, the altered crystal is called a "paramorph." For example, crystals of aragonite are often altered to a confused granular aggregate of crystalline individuals of calcite, the change being accompanied by an increase in specific gravity but without change in external form: such a change may be effected artificially by simply heating a crystal of aragonite. Other examples of paramorphs are rutile with the form of anatase, and hornblende with the form of augite. An "epimorph" results from the encrustation of one mineral by another; the first may be afterwards partly or wholly dissolved out, leaving the second as a hollow shell (*e.g.* chalybite after fluor-spar). As instances of pseudomorphs in which there has been some chemical change the following may be cited: by the gain of chemical constituents, *e.g.* malachite after cuprite; by the loss of material, *e.g.* native copper after cuprite; or by an interchange of constituents, *e.g.* galena after pyromorphite and limonite after pyrites. In other cases there may be no evident chemical relationship between the two minerals, as, for example, in pseudomorphs of native copper after aragonite or quartz after calcite. Different minerals may also take the form of various organic remains.

III.—Nomenclature and Classification of Minerals.

A mineral species, or simple mineral, is completely defined by the statement of its chemical composition and crystalline form. When we are dealing with a definite chemical compound the limitation of species is easy enough; thus corundum, cassiterite, galena, blende, &c. are quite sharply defined mineral species. But with isomorphous mixtures the division into species, or into sub-species and varieties, must be to a certain extent arbitrary, there being no sharp lines of demarcation in many isomorphous groups of minerals. Thus in the mineral tourmaline the chemical composition varies indefinitely between wide limits, but no corresponding difference can be traced in the crystalline form or in the external characters save colour and specific gravity. Some authors have therefore questioned the advisability of separating minerals into species each with distinctive names, and they have attempted to devise chemical names for the different kinds of minerals. Owing, however, to the frequency of polymorphism and isomorphism amongst mineral substances such a system presents many practical difficulties. Thus the three modifications of titanium dioxide are more simply and conveniently referred to as rutile, anatase and brookite, while to give a purely chemical designation to such a mineral as tourmaline would be quite impracticable. Further, later investigations often show that such chemical names require revision, and hence confusion may arise.

The practice of giving distinct names to different kinds of minerals dates from very early times (*e.g.* diamond). The common termination *ite* (originally *itis* or *ites*) was adopted by the Greeks and Romans for the names of stones, the names themselves indicating some character, constituent, or use of the stone, or the locality at which it was found. For example, haematite, because of the blood-red colour; siderite, containing iron; alabaster (originally alabastritis), a stone from which a vessel called an *alabastron* was cut; magnesite, from the locality Magnesia. The custom of naming minerals after persons is of modern origin; *e.g.* prehnite, biotite, haüyne, zoisite. Unfortunately there is a lack in uniformity in the termination of mineral names, many long-established names being without the termination *ite*, *e.g.* beryl, blende, felspar, garnet, gypsum, quartz, zircon, &c. The termination *ine* is also often used, *e.g.* nepheline, olivine, serpentine, tourmaline, &c.; and many others were introduced by R. J. Haüy without much reason, *e.g.* anatase, dioptase, epidote, analcime, sphene, &c. (see A. H. Chester, *A Dictionary of the Names of Minerals*, New York, 1896).

The number of known mineral species differs, of course, according to different authors; roughly there may be said to be about a thousand. The total number of mineral names (apart from chemical names), many of them being applied to trivial varieties or given in error, amount to about 5000.

Minerals may be classified in different ways to suit different purposes; thus they may be classified according to their uses, modes of occurrence, system of crystallization, &c. The earlier systematic classifications, being based solely on the external characters of minerals, were on natural history principles and too artificial to be of any value. J. J. Berzelius, in 1815, was the first to propose a purely chemical system of classification: his primary divisions depended on the basic (electro-positive) element and the sub-divisions on the acid (electro-negative) element. Such a method of classification, though still in use for metallic ores, must be quite arbitrary or give rise to much duplication; since, apart from isomorphous replacement, many minerals contain more than one metal. The systematic classifications in use at the present day are modifications in detail of the crystallo-chemical system published by G. Rose in 1852. Here there are four main divisions, viz. elements; sulphides, arsenides, &c.; halogen compounds; and oxygen compounds: the last, and largest, division is subdivided into oxides and according to the acid (carbonates, silicates, sulphates and chromates, phosphates and arsenates, &c.); in each section isomorphous minerals are grouped together. The classifications adopted by different authors differ much in detail, especially in the large section of the silicates, which presents many difficulties and for which no satisfactory classification has yet been devised.

As an example of a systematic classification of minerals the following may be given. Except in a few details it is the classification of Dana's *System of Mineralogy* (6th ed., 1892). Only those minerals which are described under their respective headings in these volumes are included: the list therefore serves, at the same time, as an enumeration of the more common and important species and varieties of minerals, and as a system of classification it is necessarily incomplete. Species belonging to the same isomorphous group are bracketed together: varieties are given in parentheses after the species to which they belong. The chemical composition of each species is given by the formula; and the crystal-system by the initial letters C (cubic), T (tetragonal), O (orthorhombic), M (monoclinic), A (anorthic), H (hexagonal) and R (rhombohedral): when the crystal class is definitely known to be some other than the holosymmetric this is indicated by a number corresponding to those used in the article Crystallography, *e.g.* C2 for the tetrahedral class of the cubic system.

I.—NATIVE ELEMENTS.

1. Non-Metals.

Diamond (Bort, Carbonado)	C	C2
Graphite	C	R
Sulphur	S	O

2. Semi-Metals.

Arsenic	As	R
Antimony	Sb	R
Bismuth	Bi	R

3. Metals.

Gold	Au	C
Silver	Ag	C
Copper	Cu	C
Platinum	Pt	C

II.—SULPHIDES, ARSENIDES, TELLURIDES, ETC.

1. Of the Semi-Metals.

Realgar	AsS	M
Stibnite	Sb_2S_3	O
Bismuthite	Bi_2S_3	O
Tetradymite	Bi_2Te_2S	R
Molybdenite	MoS_2	R

2. Of the Metals.

A. Monosulphides, &c.

Argentite	Ag_2S	C
Galena	PbS	C
Copper-glance	Cu_2S	O
Blende	ZnS	C2
Cinnabar	HgS	R3
Covellite	CuS	H
Greenockite	CdS	R2
Millerite	NiS	R
Niccolite	NiAs	R
Pyrrhotite	$Fe_{11}S_{12}$	R

B. Intermediate Division.

Erubescite	Cu_5FeS_4	C
Chalcopyrite	$CuFeS_2$	T2

C. Disulphides, &c.

Pyrites	FeS_2	C3
Smaltite	$CoAs_2$	C3
Cobaltite	CoAsS	C3
Marcasite	FeS_2	O
Mispickel	FeAsS	O
Sylvanite	$AuAgTe_4$	M

III.—SULPHO SALTS.

Freieslebenite	$(Pb,Ag_2)_5Sb_4S_{11}$	M
Bournonite	$PbCuSbS_3$	O
Pyrargyrite	Ag_3SbS_3	R2
Proustite	Ag_3AsS_3	R2
Tetrahedrite	Cu_3SbS_3	C2
Stephanite	Ag_5SbS_4	O2
Stannite	Cu_2FeSnS_4	T2
Argyrodite	Ag_8GeS_6	C

IV.—HALOIDS.

1. Anhydrous.

Salt	NaCl	C
Sylvite	KCl	C4
Cerargyrite	Ag(Cl,Br,I)	C
Fluor-spar	CaF_2	C
Cryolite	Na_3AlF_6	M

2. Oxychlorides.

Atacamite	$Cu_2Cl(OH)_3$	O

V.—OXIDES.

1. Oxides of Silicon.

Quartz (Agate, Amethyst, Avanturine, Bloodstone, Cairngorm, Carnelian, Cat's-eye, Chalcedony, Chrysoprase, Heliotrope, Jasper, Mocha-stone, Onyx, Rock-crystal, Sard, Sardonyx.)	SiO_2	R3
Tridymite	SiO_2	O(?)
Opal	SiO_2+nH_2O	Amorphous

2. Oxides of the Semi-Metals.

3. Oxides of the Metals.

A. Anhydrous Oxides.

a. Monoxides.

Cuprite	Cu_2O	C4
Zincite	ZnO	R2
Melaconite	CuO	M

b. Sesquioxides.

Corundum (Asteria, Emery, Ruby, Sapphire.)	Al_2O_3	R
Haematite	Fe_2O_3	R
Ilmenite[1]	$FeTiO_3$	R4

c. Intermediate Oxides.[2]

Spinel	$MgAl_2O_4$	C
Magnetite	$FeFe_2O_4$	C
Franklinite	$(Fe,Zn,Mn)(Fe,Mn)_2O_4$	C
Chromite	$(Fe,Mg)(Cr,Fe)_2O_4$	C
Chrysoberyl (Alexandrite, Cymophane)	$BeAl_2O_4$	O

d. Dioxides.

Cassiterite	SnO_2	T
Rutile	TiO_2	T
Anatase	TiO_2	T
Brookite	TiO_2	O
Pyrolusite	MnO_2	?
Pitchblende[3]	$(U,Th)O_2$	C

B. Hydrous Oxides.

Diaspore	AlO(OH)	O
Goethite	FeO(OH)	O
Manganite	MnO(OH)	O
Limonite	$Fe_2O_3 . 3H_2O$	Amorphous
Bauxite	$Al_2O_3 . 2H_2O$?	,,
Brucite	$Mg(OH)_2$	R
Psilomelane (Wad)	$xMnO_2+yBaO+H_2O$	Amorphous

VI.—OXYGEN SALTS.

1. Carbonates.

A. Anhydrous.

Calcite (Satin-spar)	$CaCO_3$	R
Dolomite	$CaMg(CO_3)_2$	R4
Ankerite	$Ca(Mg,Fe)(CO_3)_2$	R
Magnesite	$MgCO_3$	R
Chalybite	$FeCO_3$	R
Rhodochrosite	$MnCO_3$	R
Calamine	$ZnCO_3$	R
Aragonite	$CaCO_3$	O
Alstonite	$(Ca,Ba)CO_3$	O
Witherite	$BaCO_3$	O
Strontianite	$SrCO_3$	O
Cerussite	$PbCO_3$	O
Barytocalcite	$CaBa(CO_3)_2$	M
Parisite	$(CeF)_2Ca(CO_3)_3$	H
Phosgenite	$(PbCl)_2CO_3$	T

B. Basic Carbonates.

Malachite	$Cu_2(OH)_2CO_3$	M
Azurite	$Cu_3(OH)_2(CO_3)_2$	M

2. Silicates.

A. Anhydrous Silicates.

a. Disilicates, $R''Si_2O_5$; *Polysilicates*, $R''Si_3O_8$.

		Petalite	$LiAl(Si_2O_5)_2$	M
Felspar Group.		Orthoclase (Moon-stone)	$KAlSi_3O_8$	M
		Microcline (Amazon-stone)	$KAlSi_3O_8$	A
	Plagioclase.	Albite	$NaAlSi_3O_8$	A
		Oligoclase (Sun-stone)	Ab_6An_1 to Ab_3An_1	A
		Andesine	Ab_3An_1 to Ab_1An_1	A
		Labradorite	Ab_1An_1 to Ab_1An_3	A
		Bytownite	Ab_1An_3 to Ab_1An_6	A
		Anorthite	$CaAl_2Si_2O_8$	A

b. Metasilicates, $R''SiO_3$.

	Leucite	$KAl(SiO_3)_2$	Pseudo-C
	Pollux	$H_2Cs_4Al_4(SiO_3)_9$	C
Pyroxene Group.	Enstatite	$MgSiO_3$	O
	Bronzite	$(Mg,Fe)SiO_3$	O
	Hypersthene	$(Fe,Mg)SiO_3$	O
	Diopside	$CaMg(SiO_3)_2$	M
	Augite (Diallage)	$Ca(Mg,Fe)(SiO_3)_2$ with $(Mg,Fe)(Al,Fe)_2SiO_6$	M
	Acmite	$NaFe'''(SiO_3)_2$	M
	Spodumene (Hiddenite, Kunzite)	$LiAl(SiO_3)_2$	M
	Jadeite	$NaAl(SiO_3)_2$	M
	Wollastonite	$CaSiO_3$	M
	Rhodonite	$MnSiO_3$	A
Amphibole Group.	Tremolite	$CaMg_3(SiO_3)_4$	M
	[Actinolite] (Asbestos, Nephrite)	$Ca(Mg,Fe)_3(SiO_3)_4$	M
	Hornblende	$Ca(Mg,Fe)_3(SiO_3)_4$ with $NaAl(SiO_3)_2$ and $(Mg,Fe)(Al,Fe)_4(SiO_6)_2$	M
	Crocidolite	$NaFe(SiO_3)_2 . FeSiO_3$	M
	Beryl (Aquamarine, Emerald)	$Be_3Al_2(SiO_3)_6$	H

c. Intermediate.

Iolite	$H_2(Mg,Fe)_4Al_8Si_{10}O_{37}$	O

---

[1] Often classed with the titanates.

[2] Often classed as aluminates.

[3] Usually classed as a uranate.

	d. *Orthosilicates*, R''_2SiO_4.		
	Nepheline	$K_2Na_6Al_8Si_9O_{34}$	H5
	Sodalite	$Na_4(AlCl)Al_2(SiO_4)_3$	C
	[Lazurite] (Lapis-lazuli)	$Na_4(NaS_3.Al)Al_2(SiO_4)_3$	C
	[Grossularite] (Cinnamon-stone)	$Ca_3Al_2(SiO_4)_3$	C
	Pyrope	$Mg_3Al_2(SiO_4)_3$	C
	Almandine	$Fe_3Al_2(SiO_4)_3$	C
	[Andradite] (Demantoid)	$Ca_3Fe_2(SiO_4)_3$	C
	Olivine (Chrysolite, Peridot)	$(Mg,Fe)_2SiO_4$	O
	Phenacite	Be_2SiO_4	R4
	Willemite	Zn_2SiO_4	R4
	Dioptase	H_2CuSiO_4	R4
	Scapolite	$mCa_4Al_6Si_6O_{25}$ $nNa_4Al_3Si_9O_{24}Cl$	T3
	Vesuvianite	$H_2Ca_6(Al,Fe)_3Si_5O_{18}$	T
	Zircon (Hyacinth, Jacinth, Jargoon)	$ZrSiO_4$	T
	Thorite	$ThSiO_4$	T
	Danburite	$CaB_2(SiO_4)_2$	O
	Topaz	$[Al(F,OH)]_2SiO_4$	O
	Andalusite	Al_2SiO_5	O
	Sillimanite	Al_2SiO_5	O
	Cyanite	Al_2SiO_5	A
	Datolite	$HCaBSiO_5$	M
	Euclase	$HBeAlSiO_5$	M
	Zoisite	$Ca_2(AlOH)Al_2(SiO_4)_3$	O
	Epidote	$Ca_2(AlOH)\ (Al,Fe)_2(SiO_4)_3$	M
	Axinite	$HCa_3BAl_2(SiO_4)_4$	A
	Prehnite	$H_2Ca_2Al_2(SiO_4)_3$	O2
	e. *Subsilicates.*		
	Humite	$Mg_5[Mg(F,OH)]_2(SiO_4)_3$	O
	Hemimorphite	$H_2Zn_2SiO_5$	O2
	Tourmaline (Rubellite)	$(H_2,Na_2,Mg)_3(Al,Fe)_6(BOH)_4Si_8O_{38}$	R2
	Staurolite	$HFeAl_5Si_2O_{13}$	O
	B. Hydrous Silicates.		
	Apophyllite	$H_7KCa_4(SiO_3)_8+4\frac{1}{2}H_2O$	T
Zeolite Group.	Heulandite	$H_4CaAl_2(SiO_3)_6+3H_2O$	M
	Phillipsite	$(K_2.Ca)Al_2(SiO_3)_4+4H_2O$	M
	Harmotome	$H_2(K_2,Ba)Al_2(SiO_3)_5+5H_2O$	M
	Stilbite	$(CaAl_2(SiO_3)_6+6H_2O$	M
	Chabazite	$(Ca,Na_2)Al_2(SiO_4)_2+4H_2O$,&c.	R
	Analcite	$NaAl(SiO_3)_2+H_2O$	C
	Natrolite	$Na_2Al_2Si_3O_{10}+2H_2O$	O
	Scolecite	$CaAl_2Si_3O_{10}+3H_2O$	M3
Mica Group.	Muscovite	$H_2KAl_3(SiO_4)_3$	M
	Lepidolite	$KLi[Al(OH,F)_2]Al(SiO_3)_3$	M
	Biotite	$(H,K)_2(Mg,Fe)_2Al_2(SiO_4)_3$,&c.	M
	Phlogopite	$[H,K,(MgF)]_3Mg_3Al(SiO_4)_3$	M
	Clintonite	$H_2(Fe,Mg)Al_2SiO_7$,&c.	M
	Chlorite	$H_8(Mg,Fe)_5Al_2Si_3O_{18}$,&c.	M
	Serpentine	$H_4Mg_3Si_2O_9$	M
	Talc	$H_2Mg_3(SiO_3)_4$	M
	Meerschaum	$H_4Mg_2Si_3O_{10}$	Amorphous
	Kaolin (Bole, Clay)	$H_4Al_2Si_2O_9$	M
	Pyrophyllite	$HAl(SiO_3)_2$	M?
	Allophane	$Al_2SiO_5+5H_2O$	Amorphous
	Chrysocolla	$CuSiO_3+2H_2O$	,,
	C. Titano-silicates, Titanates.		
	Sphene	$CaTiSiO_5$	M
	Perofskite	$CaTiO_3$	Pseudo-C
	3. NIOBATES, TANTALATES.		
	Columbite	$(Fe,Mn)(Nb,Ta)_2O_6$	O
	4. PHOSPHATES, ARSENATES, &c.		
	A. Anhydrous Phosphates, &c.		
	Monazite	$(Ce,La,Di)PO_4$	M
	Beryllonite	$NaBePO_4$	O
	Apatite (Phosphorite)	$[Ca(F,Cl)]Ca_4(PO_4)_3$	H2
	Pyromorphite	$(PbCi)Pb_4(PO_4)_3$	H2
	Mimetite	$(PbCl)Pb_4(AsO_4)_3$	H2
	Vanadinite	$(PbCl)Pb_4(VO_4)_3$	H2
	Amblygonite	$Li(AlF)PO_4$	A
	B. Basic Phosphates, &c.		
	Olivenite	$Cu_2(OH)AsO_4$	O
	Descloizite	$(Pb,Zn)_2(OH)VO_4$	O
	Clinoclasite	$Cu_3(OH)_3AsO_4$	M
	C. Hydrous Phosphates, &c.		
	Vivianite	$Fe_3(PO_4)_2+8H_2O$	M
	Erythrite	$Co_3(AsO_4)_2+8H_2O$	M
	Annabergite	$Ni_3(AsO_4)_2+8H_2O$	M
	Wavellite	$Al_3(OH)_3(PO_4)_2+4\frac{1}{2}H_2O$	O
	Turquoise	$[Al(OH)_2,Cu(OH),H]_3PO_4$	Amorph.
	Pharmacosiderite	$Fe_3(OH)_3AsO_4+5H_2O$	C2
	Childrenite	$(Fe,Mn)Al(OH)_2PO_4+H_2O$	O
	Liroconite	$Cu_3Al_4(OH)_{15}(AsO_4)_5+20H_2O$	M
	Torbernite	$Cu(UO_2)_2(PO_4)_2+12H_2O$	T
	Autunite	$Ca(UO_2)_2(PO_4)_2+12H_2O$	O
	5. BORATES.		
	Boracite	$Mg_7Cl_2B_{16}O_{30}$	Pseudo-C2

MINERAL WATERS. No absolute line of demarcation can be drawn between ordinary and mineral waters. There is usually in the latter an excess of mineral constituents or of temperature, but some drinking waters contain more mineral constituents than others that are called mineral waters, and many very pure waters, both cold and warm, have been regarded for ages as mineral springs.

As to the origin of mineral waters, there is much in what the elder Pliny said, that waters are such as the soil through which they flow. Thus in limestone and chalk districts an excess of lime is usually present; and the waters of a particular district have much resemblance to each other—as in the Eifel, in Auvergne, and in the Pyrenees. But this is only a partial explanation, for waters are by no means necessarily uniform throughout a particular geological formation. We do not know with any certainty the depth from which various mineral waters proceed, nor the various distances from the surface at which they take up their different mineral constituents.

The source of the temperature of thermal waters remains a subject of much uncertainty. Among the assigned causes are the internal heat of the globe, or the development of heat by chemical or electrical agencies in the strata through which they arise.

Their occasional intermittence is doubtless often dependent on the periodical generation of steam, as in the case of the Geysers. A few geological facts are certain, which bear on the origin of mineral waters. Such springs are most abundant in volcanic districts, where many salts of soda and much carbonic acid are present. They occur most frequently at meetings of stratified with unstratified rocks, in saddles, and at points where there has been dislocation of strata.

The diffusion of mineral waters is very extended. Pliny was quite correct in observing that they are to be found on alpine heights and arising from the bottom of the ocean. They are found at the snow in the Himalayas and they rise from the sea at Baiae and Ischia. They are to be found in all quarters of the globe, but more particularly in volcanic regions, as in the Eifel and Auvergne, in the Bay of Naples, and parts of Greece, in Iceland, New Zealand and Japan. But there are few countries in which they are not to be found, except in very flat ones, and in deltas of rivers—for instance, in the north of France, where they are very few, and in Holland, from which they are absent. France, Germany, Italy and Spain, as well as Greece, Asia Minor, and the Caucasus, are all rich in mineral waters. The British Isles have a fair though not very large proportion of them. There are a few in Sweden and Norway. They are abundant in the United States, less so in Canada. They are found in the Azores and in the West India Islands. Of their occurrence in the interior of Africa or of Australia we know little; and the same is true of South America. But they are met with in Algiers, in Egypt, and in the Holy Land. The vast Indian peninsula has for its size a comparatively small supply.

Mineral waters, when analysed, are found to contain a great many substances, although some of them occur only in very minute quantities: soda, magnesia, calcium, potash, alumina, iron, boron, iodine, bromine, arsenic, lithium, caesium, rubidium, fluorine, barium, copper, zinc, manganese, strontium, silica, phosphorus, besides extractive matters, and various organic deposits known under the name of glairin or baregin. Of gases, there have been found carbonic acid, hydrosulphuric acid, nitrogen, hydrogen, oxygen and ammonia. Of all these by far the most important in a therapeutic point of view are sodium, magnesia and iron, carbonic acid, sulphur, and perhaps hydrosulphuric acid. These substances, detected separately by chemists, are in their analyses combined by them into various salts, if not with absolute certainty, undoubtedly with a close approximation to it. Those combinations are very numerous, and some waters contain ten to twenty of them; but there are always some predominating ones which mark their character, while many of them, such as caesium, rubidium, or fluorine, occur in mere traces, and cannot be assumed to be of any real importance. Mineral waters therefore resolve themselves into weaker or stronger solutions of salts and gases in water of higher or lower temperature. For medical purposes they are used either externally or internally. As the quantity of salts present commonly bears but a very small proportion to that of the fluid containing them, water becomes a very influential agent in mineral-water treatment, about which it is therefore necessary to say something.

For the action of mineral-water baths see BALNEOTHERAPEUTICS. According to the most generally received opinion, the cutaneous surface does not absorb any portion of the salts in a mineral-water bath, although it may absorb a little gas (and alkaline water, for instance, at most acting as a slight detergent on the skin), and that neither salts nor gases have any action on the system, except as stimulants of the skin, with partial action on the respiratory organs.

It seems to be ascertained that drinking considerable amounts of cold water reduces the temperature of the body, diminishes the frequency of the pulse, and increases the blood pressure temporarily. Water when introduced into the stomach, especially if it be empty, is quickly absorbed; but, although much of the water passes into the veins, there is no proof that it ever produces in them, as is sometimes supposed, a state of fluidity or wateriness. Therapeutically, the imbibition of large quantities of water leads to a sort of general washing out of the organs. This produces a temporary increase of certain excretions, augmented diuresis, and a quantitative increase of urea, of chloride of sodium, and of phosphoric and sulphuric acids in the urine. Both the sensible and the insensible perspirations are augmented. A draught of cold water undoubtedly stimulates the peristaltic action of the intestines. On the whole water slightly warm is best borne by the stomach, and is more easily absorbed by it than cold water; and warm waters are more useful than cold ones when there is much gastric irritability. In addition to the therapeutic action of mineral waters, there are certain very important subsidiary considerations which must not be overlooked. An individual who goes from home to drink them finds himself in a different climate, with possibly a considerable change in altitude. His diet is necessarily altered, and his usual home drinks are given up. There is change in the hours of going to bed and of rising. He is relieved from the routine of usual duties, and thrown into new and probably cheerful society. He takes more exercise than when at home, and is more in the open air, and this probably at the best season of the year. So important has this matter of season and climate been found that it is an established axiom that waters can be used to the greatest advantage during the summer months and in fine weather, and during the periods most convenient for relaxation from business. Summer is therefore the bath season, but of late years provision has been made in many places, with the aid of specially constructed rooms and passages, for carrying out cures satisfactorily during the winter season, *e.g.* at Aix-la-Chapelle, Wiesbaden, Baden Baden, Baden in Switzerland, Dax, Vichy and Bath. The ordinary bath season extends from the 15th of May to the 20th or 30th of September. The season for baths situated at considerable elevations commences a month later and terminates some ten days earlier. Mineral waters may be employed at home, but patients seldom so use them; and this necessarily limits the time of their use. It is common to declare that the treatment should last for such or such a period. But the length of time for which any remedy is to be used must depend on its effect, and on the nature of the particular case. It is found, however, that the continued use of mineral waters leads to certain disturbances of the system, which have been called crises, such as sleeplessness, colics and diarrhoea, and to skin eruptions known as *la poussée*. This cause, and also certain peculiarities of the female constitution, have led to the period of three weeks to a month being considered the usual period for treatment. A certain after-treatment is often prescribed—such as persistence in a particular diet, visiting springs or climates of a different and usually of a tonic character, or continuing for a certain time to drink the waters at home. It may be added that the advantage of having recourse to mineral waters is often felt more after than during treatment.

Since improved methods of bottling have been discovered, and the advantage of an additional supply of carbonic acid has been appreciated, the export of waters from their sources has increased enormously, and most of the principal waters can now be advantageously used at home. It may be added that many of the artificial imitations of them are excellent.

The history of the use of mineral waters can only just be alluded to. They have been employed from the earliest periods, and traces of Roman work have been found at most of the European baths which are now in favour—at almost all the thermal ones. Occasionally new springs are discovered in old countries, but the great majority of them have been long known. Warm waters, and those containing small quantities of mineral constituents, appear to have remained more steadily in favour than any other class within the appropriate sphere of mineral waters, which is limited to the treatment of chronic disease.

The attempt has been made to range mineral waters according to their therapeutic action, according to their internal or external use, but most generally according to their chemical constituents so far as they have been from time to time understood; and a judicious classification undoubtedly is a help towards their rational employment. But their constituents are so varied, and the gradations between different waters are so finely shaded off, that it has been found impossible to propose any one definite scientific classification that is not open to numberless objections. Thus a great many of the sulphur waters are practically earthy or saline ones. Yet because they contain very minute amounts of such a gas as hydrosulphuric acid, an ingredient so palpable as always to attract attention, it is considered necessary to class them under the head of sulphur. The general rule is to attempt to class a water under the head of its predominant element; but if the amount of that be extremely small, this leads to such waters as those of Mont Dore being classified as alkaline or arseniated, because they contain a very little soda and arsenic. The classification in the following table, which is that usually adopted in Germany, has the merit of comparative simplicity, and of freedom from theoretical considerations which in this matter influence the French much more than the German writers. The more important constituents only are given. The amount of solid constituents is the number of parts to one thousand parts of the water; the temperature of thermal springs is added. The waters are classified as indifferent, earthy, salt, sulphuretted, iron, alkaline, alkaline-saline—with subvarieties of table waters and purging waters.

In addition to their solid constituents, gas is present in many waters in considerable quantity. There is a little oxygen and a good deal of nitrogen in some of them; the quantity of hydrosulphuric acid, even in strong sulphuric waters, is wonderfully small; but the volume of carbonic acid present is often very large—for instance, in the case of Kissingen, Schwalbach and Selters. The immediate effect of the carbonic acid which they contain is that of pleasant stimulation to the stomach and system. Extremely little appears to be known of its actual operation on the system: a part of what is swallowed is returned by eructation, and a part passes on to the intestines; whether any appreciable quantity reaches the blood is doubtful. There is no question that carbonic acid increases diuresis. Practically it is found to aid digestion, helping the functions of the stomach, and in a slight degree the peristaltic action of the intestines. The increased flow of urine may be caused by its favouring the absorption of water by the stomach. In some baths carbonic acid is so abundant that precautions have to be taken to prevent its tendency to accumulate on account of its heavy specific gravity. Carbonic acid gas, used as a bath, proves stimulating to the skin and to the general system; but its employment has not answered the expectations formed of it.

TABLE II.[1]—*Indifferent Waters.*

Locality.	Height in Ft.	Temp. °Fahr.	For what prescribed.
Evian, Lake of Geneva	1100	—	Nervous cases, dyspepsia, urinary affections.
Badenweiler, Baden	1425	—	For mild rheumatic treatment; a health resort.
Buxton, England	980	82	Gout and rheumatism (nitrogen present).
Schlangenbad, Nassau	800	80–87	Nervous cases, female disorders, skin.
Sacedon, Spain	1500	85	Rheumatism, gout, cutaneous affections.
Wildbad, Württemberg	1320	90–101	Gout and rheumatism, neuralgia, thickenings.
Pfeffers, Switzerland	2115	99	Do. do. do.
Ragatz, do.	1570	95	Do. do. do.
Panticosa, S. Pyrenees	5110	85–95	Do. (nitrogen present); special action in phthisis.
Teplitz, Bohemia	648	101–120	Gout, rheumatism, old injuries, joints or bones.
Gastein, Austria	3315	95–118	Do. do.; soothes nervous system.

Indifferent Waters scarcely vary in chemical qualities from ordinary drinking water; but they are usually of higher temperature. Their therapeutic action, which is mainly exercised through baths, has been explained on the theory of peculiarities of their electric or thermal condition, about which we know nothing definite, and on the presence in some of them of a large quantity of nitrogen. It has also been ascribed to the various organic substances in some of them; such as glairin, which when collected is sometimes useful as a cataplasm. These waters are not often much drunk, but any efficiency they may have in dyspepsia and perhaps in neuralgic diarrhoeas must be attributed to the favourable action of hot water on the digestion. The waters of this class, especially the hotter ones in the form of baths, are extremely useful in resolving the effects of inflammation, in thickenings of the joints and in chronic rheumatism and gout. They also are often effective, especially the cooler ones, in neuralgia and in some hysterical affections. They are sometimes prescribed in urinary affections, in which case they probably assist by dilution. The effects of many of these waters are aided by the baths often being situated at considerable elevations and in out-of-the-way spots, whence the Germans called them *Wildbäder*. They are very widely diffused, being found in all quarters of the globe, especially in volcanic districts. There are many in New Zealand; in America the hottest are in the west and in California.

---

[1] In this and the following tables a selection is given of some of the best-known mineral waters in various European countries that possess establishments. Their chief peculiarities of elevation, of temperature and constituents are briefly noted. The curative effects, necessarily alluded to very generally, are those usually attributed to them.

Earthy Waters.—These differ chiefly from the indifferent waters in containing an appreciable quantity of salts, among which sulphate or carbonate of lime or of magnesia predominates. The great majority of them are of high temperature. They produce the same effects as the indifferent waters, but are perhaps less efficacious in neuralgic affections, while they are more employed in some of the chronic scaly eruptions. There was formerly a tendency to consider these waters useful in urinary affections; but at the present day it is only the colder ones that have come into repute for the expulsion of gravel and biliary calculi and in the treatment of affections of the bladder generally. Some of them have also of late years been considered to exercise a favourable influence on scrofula, and to be useful in the early stages of pulmonary phthisis. This has been attributed to the salts of lime present in them, although it is known that most of its salts pass through the system unaltered. Many of these baths, such as Leuk and Bormio, enjoy the advantages of great elevation, but Bath, otherwise one of the best of them, lies low.

TABLE III.—*Earthy Waters*.

	Locality.	Height in Ft.	Temp. ° Fahr.	Therapeutic Action.
Cold.	Contrexéville, Vosges	1050	—	Special action in calculous affections.
	Lippspringe, N. Germany	—	—	Supposed to be useful in phthisis.
	Wildungen, do.	—	—	Special use in urinary complaints; contains iron.
	Weissenberg, Switzerland	2600	—	Resorted to for pulmonary affections.
	Pougues, France	600	—	Dyspepsia, diabetes, hepatic and urinary concretions.
Warm.	Baden, Switzerland	1180	117–122	Rheumatism, gout, paralysis, scaly eruptions.
	Leuk, do.	4400	93–123	Do., some female complaints.
	Bormio, North Italy	4400	86–104	Do. do.; old sprains.
	Lucca, Italy	—	108–122	Do. do. do.
	Bath, England	—	108–122	Do. do. do.
	Dax, south of France	1400	139	Do. do.
	B. de Bigorres, Pyrenees	1800	64–123	Do.; chlorosis, neuralgia.

Salt Waters are so called from containing a predominant amount of chloride of sodium. They also generally contain chlorides of magnesia and of lime, and occasionally small amounts of lithium, bromine and iodine. They further often contain a little iron, which is an important addition. The great majority of the drinking wells have a large supply of carbonic acid. There are cold and hot salt springs. Sometimes they are used for drinking, sometimes for bathing; and the double use of them is often resorted to.

The normal quantity of common salt consumed daily by man is usually set down at about 300 grains. The maximum quantity likely to be taken at any well may be 225 grains, but commonly not more than half of that amount is taken. The increase to the usual daily amount is therefore probably not much more than one-third. Still it may be presumed that the action of a solution of salt on an empty stomach is different from that of the same amount of salt taken with food. Salt introduced into the stomach excites the secretion of gastric juice and favours the peristaltic actions, and when taken in considerable quantity is distinctly aperient. We thus see how it is useful in dyspepsia, in atony of the stomach and intestines, and sometimes in chronic intestinal catarrh. Salt when absorbed by the stomach appears again in the urine, of which it increases the amount both of fluid and of solid constituents, especially of the urea. It seems, therefore, to be pretty certain that considerable quantities of salt taken into the circulation increase the excretion of nitrogenous products through the urine, and on the whole accelerate the transformation of tissue. Salt is thus useful in scrofula by stimulating the system, and also in anaemia, especially when iron is also present. In some German stations, as at Soden, carbonated salt waters are considered to be useful in chronic laryngitis or granular pharyngitis.

Baths of salt water, as usually given, rarely contain more than 3% of chloride of sodium, some of the strongest perhaps from 8 to 10%. Their primary action is as a stimulant to the skin, in which action it is probable that the other chlorides, especially that of calcium, and still more the carbonic acid often present, co-operate. In this way, and when aided by various processes of what may be termed water poultices and packing, they are often useful in removing exudations, in chronic metritis and in some tumours of the uterus, and generally in scrofula and rachitis, and occasionally in some chronic skin affections.

The French accord high praise to some of their thermal salt waters in paralysis, and some German ones are used in a similar way in spinal affections. The salt waters are sometimes so strong that they must be diluted for bathing. In other cases concentrated solutions of salt are added to make them sufficiently strong. These waters are widely diffused, but on the whole Germany is richest in them, especially in such as are highly charged with salt. The Kissingen springs may be considered as typical of the drinking wells, and sea-water of bathing waters. The air of salt-works and pulverization of the water are employed in German baths as remedial agents.

Salt springs are found in many quarters of the world, but the chief carbonated groups for drinking purposes occur in Germany, and at Saratoga in America, where very remarkable wells indeed are to be found. France and England have no springs of this class. The stronger wells, used chiefly for bathing, occur where there are salt-bearing strata, as in Germany, Galicia, Italy, Switzerland, France and England. Very powerful waters of this class are those of St Catherines in Canada.

TABLE IV.—*Salt Springs*.

	Locality.	Temp. ° Fahr.	Therapeutic Action.
Cold.	Soden, near Frankfort	—	Dyspepsia, anaemia, scrofula, special for throat and phthisis.
	Homburg, do.	—	Dyspepsia, slighter hepatic affections, chlorosis, gout.
	Kissingen, Bavaria	—	In all essentials the same.
	Pyrmont, North Germany	—	Better known for its iron; has a good salt drinking spring.
	Kreuznach, near Bingen	—	A salt well without carbonic acid; used in scrofula and anaemia; bathing more important.
Warm.	Wiesbaden, Nassau	155	Used in dyspepsia and gout; the bathing is most important.
	Baden-Baden	156	Still milder water; uses similar; gout.
	Bourbonne, Haute-Marne	114–149	Rheumatism, neuralgia, effects of malaria.
	Balaruc, South France	116·6	Do.; special for treatment of paralysis.
	Salins, Moutiers, Savoy (1480 ft.)	96	Scrofula, anaemia, loss of power, sexual disorders.
	Brides, Savoy (1700 ft.)	95	Act on liver and digestive canal; used for obesity.
	Acqui, North Italy	169	Rheumatism; special treatment with the bath deposit.
	Abano, do	185	Chiefly as baths; mud of bath used for poultice.
	Caldas de Mombuy, near Barcelona	153–158	Rheumatism, sciatica, old injuries.
	Cestona, Guipuzcoa, Spain	88–94	Rheumatism, indigestion, bronchitis.

Almost all the above stations have several springs of various strengths: the cold may be said to vary from 14 to 5·8% of chloride of sodium; the warm are generally weaker, perhaps varying from 6·8 to 1·6.

The presence of minute portions of *iodine* or *bromine* in salt waters is by no means infrequent, and they appear in considerable quantity in some few. It is, however, extremely doubtful whether any known spring contains a sufficient quantity of iodine, still more of bromine, to act specially on the system, even if that action were not necessarily superseded by the presence of the large quantity of other salts with which they are associated. Some of the best-known springs of the kind are: Challes, Wildegg, Castrocaro, Hall, Adelheid's Quelle, Krankenheil, Kreuznach, Woodhall Spa.

Iron or Chalybeate Waters.—Iron usually exists in waters in the state of protoxide or its carbonate, less frequently as sulphate or crenate, and very rarely, if at all, as chloride. The quantity present is usually extremely small. It may be said to vary from 0·12 to 0·03 in the 1000 parts of water. Some wells considered distinct chalybeates contain less than 0·03. Many wells, especially in Germany, have a rich supply of carbonic acid, which is unfortunately wanting in French and English ones.

It has long been the prevalent idea that want of iron in the blood is the main cause of chlorosis and of other anaemic conditions, and that these conditions are best relieved by a supply of that metal. Since the detection of it in haemoglobuline this view has been still more popular. It is pretty certain that the blood contains 37 to 47 grains and the whole system 70 to 74 grains of iron; and it has been calculated that in normal conditions of the system somewhat more than one grain of iron is taken daily in articles of food, and that the same amount is passed in the faeces; for although the stomach takes the iron up it is excreted by the alimentary canal mainly, it being doubtful whether any is excreted in the urine. It is possible by drinking several glasses to take in more than a grain of carbonate of iron in the day, equivalent to half that amount of metallic iron. It has further been ingeniously reckoned from practice that 10 to 15 grains of metallic iron suffice to supply the deficiency in the system in a case of chlorosis. It is thought probable that a portion of the iron taken up in water is in certain pathological states not excreted, but retained in the system, and goes towards making up the want of that metal. But whether this or any other explanation be satisfactory, there is no question as to the excellent effects often produced by drinking chalybeate waters (especially when they are carbonated), and by bathing in those which are rich in carbonic acid after they have been artificially heated. As regards the drinking cure we must not, however, forget that carbonate and chloride of sodium, and also the sulphate, are often present and must be ascribed a share in the cure. Thus chloride of sodium is a powerful adjuvant in the strong Stahl Quelle of Homburg and in the Putnam Well at Saratoga. A whole category of female complaints is treated successfully with these waters. Indeed, anaemia from any source, as after fever or through loss of blood, and enlargements of the spleen, are benefited by them. The stimulating action of the copious supply of carbonic acid in steel baths is a very important adjuvant; no one now believes in direct absorption of iron from the bath. Iron waters are scarcely ever thermal. They are extremely common in all countries—frequently along with sulphuretted hydrogen in bogs and near coal-measures. But such springs and non-carbonated wells generally are weak, and not now held in much esteem.

Muspratt Spring, Harrogate (chloride)	600	0·15	

It may be added that some of the strongest known iron wells are *sulphated* or *aluminated*. They are styptic and astringent, and can only be used diluted. They are sometimes useful as an application to ulcers and sores. Such springs have often been brought into notice, but never retain their popularity. They are known in the Isle of Wight, in Wales, in Scotland, as well as in Elba, &c.; and of late years the Bedford Alum and Oak Orchard Springs, U.S., have been brought into notice, the latter containing 10 grains of free sulphuric acid in the pint. All such springs have been considered useful in scrofula, anaemia and chronic diarrhoeas.

Sulphur Springs.—Waters having the odour of hydrosulphuric acid, however slightly, are usually called sulphur ones. They owe their smell sometimes to the presence of the free acid, sometimes to sulphides of sodium, calcium or magnesia, and sometimes to both. Sulphuretted hydrogen is absorbed more freely by cold than by hot water, and is therefore most abundant in cold springs. The sulphides decompose and give off the gas. Most of these springs occur near coal or shale measures, or strata containing fossils, or in moors and in places generally where organic matter is present in the soil or strata. Many of them contain so little mineral impregnation that they might as well be classed among the indifferent or earthy waters. One group contains a considerable amount of chloride of sodium, another of sulphate of lime, while a third has little mineral impregnation, but contains sulphides.

Sulphuretted hydrogen is a strong poison, and its action on the system has been pretty well ascertained. It has been assumed that the gas in mineral waters acts similarly, though in a modified degree; but there is next to nothing absolutely known of the action of the small quantities of the gas that are present in mineral waters, and which certainly have no toxic effect. It has been assumed that this gas has some special action on the portal system and so on the liver. On the connexion of metallic poisoning with the liver has been founded the idea that sulphur waters are useful in metallic intoxication. Drinking large quantities of these waters, especially of such as contain sulphates or chlorides of sodium or magnesia, combined with hot baths and exercise, may help to break up albuminates, but there is no proof of the action of the sulphur.

For similar reasons, and primarily to counteract mercurial poison, sulphur waters have been considered useful in syphilis. But it may be well to remember that at most baths mercury is used along with them. No doubt they are frequently, like other warm waters, useful in bringing out old eruptions, acting in this way as a test for syphilitic poison, and in indicating the treatment that may be required. Sulphur waters, both hot and cold, are used in gout and rheumatism, in dyspepsia, in hepatic and cutaneous affections; and of late years inhalation of them has been popular in phthisis and in laryngeal affections. They have long been popular remedies in cutaneous affections. While so much doubt has been cast on the action of the sulphur of these waters, it may be admitted that the sulphides are probably decomposed in the stomach and sulphuretted hydrogen generated. That gas is probably a slight stimulant

to the intestine. What sulphuretted hydrogen reaches the blood is eliminated by the lungs. There seems to be no doubt that the gas is absorbed in small quantities by the skin.

It is in sulphur waters chiefly that glairin and baregin occur. This peculiar organic substance has been found both in American and in European springs. Cold sulphur springs are very widely diffused throughout the world. Thermal ones are not so common. Perhaps the largest though not the strongest group of the latter is to be found in the Pyrenees. We may remark again how very little hydrosulphuric acid there is in many of the most favourite sulphur springs, including the very popular White Sulphur ones of Virginia. There seems to be something peculiarly unsatisfactory in the analysis of sulphur waters, and there has been difficulty in constructing the following imperfect tables.

Archena, Murcia, Spain	—	126	—	—

Some of the most powerful cold wells are those of Challes (with its very peculiar water), Leuk and Harrogate. Uriage has a very large amount of chloride of sodium in its springs. Cold sulphur waters are on the whole more used in liver and indigestion than warm ones. The general effects of warm sulphur waters differ so little at the various baths as to make it difficult to mention anything special to particular localities. Schinznach has a reputation in skin complaints, Cauterets, Eaux Bonnes and Challes in laryngeal affections, the two Aix, Luchon and Archena in syphilis.

Alkaline Waters are such as contain carbonate (chiefly bicarbonate) of soda, along with an excess of carbonic acid. Of the action of those carbonates it is known that when taken into the stomach they are neutralized by the gastric juice, and converted into chloride of sodium. On their introduction into the stomach they produce an increased flow of gastric juice. If given during or immediately after meals in any quantity, they impede digestion. They slightly increase peristaltic action, but only feebly, unless assisted by other salts. They act slightly as diuretics. Of the connexion between the biliary system and alkalies, which undoubtedly exists, not much is known with certainty. The alkalization of the blood by them is assumed by many, but not proved. It is very doubtful whether they reduce the quantity of fibrine in the blood, and thus induce a lowered state of the system, or whether they have any direct tendency to combine with fat and carry off a portion of superfluous adipose tissue. Their excess of carbonic acid, through its action on the stomach, favours the operation of alkaline waters. They have been classed as follows: (1) simple alkalines, where carbonate of soda is the main agent; (2) waters containing in addition some chloride of sodium; (3) waters containing sulphates of soda or of magnesia. All these classes may be said to be used in gout, lithiasis, affections of the liver, catarrh and obstructions of the gall ducts, in dyspepsia, chronic catarrh of the stomach and diarrhoea, in obesity and in diabetes. Some of the waters of the second class are supposed to influence bronchial catarrhs and incipient phthisis, while the more powerful sulphated waters of the third class are especially useful in catarrh of the stomach, and in affections of the biliary organs; of these only one of importance (Carlsbad) is thermal. The rival cold waters of Tarasp contain twice as much carbonate of soda. The cold ones are chiefly used internally, the thermal ones both internally and externally. The latter, besides acting as warm water, slightly stimulate the skin when the carbonic acid is abundant, and the carbonate of soda has some slight detergent effect on the cutaneous surface like soap. These waters are unknown in England. They are most abundant in countries of extinct volcanoes.

Classes I. and II. of alkaline waters may be said to have a subvariety in *acidulated* springs or carbonated waters, in which the quantity of salts is very small, that of carbonic acid large. These table waters are readily drunk at meals. They have of late years been so widely exported as to be within the reach almost of every one. Their practical importance in aiding digestion is in reality much greater than one could expect from their scanty mineralization. They are drunk by the country people, and also largely exported and imitated. They are very abundant on the Continent, and, although some of the best-known ones enumerated below are German and French, they are common in Italy and elsewhere: Heppingen, Roisdorf, Landskro, Apollinaris, Selters, Brückenau, Gieshübel, all German; St Galmier, Pougues, Chateldon, French.

Associated with Class III. is that of the strongly *sulphated* waters known in Germany as bitter or purging waters, which have of late deservedly come into use as purgative agents. They are almost wanting in France and in America, and there are no very good ones in England. The chief supply is from Bohemia and Hungary. The numerous waters of Ofen are the best known, and some of them are stronger than the Hunyadi, of which an analysis has been given in Table I. They are easily imitated. Some of the best-known are Ofen, Püllna, Saidschütz, Friedrichshall, Birmerstorff, Kissingen.

TABLE IX.—*Alkaline Waters.*

CLASS I.—*Simple Alkaline.*

Locality.	Carb. Soda.	Therapeutic Uses.
Vals, South France	7·1	Catarrh of stomach, gout, renal and biliary calculi, liver complaints, diabetes.
Bilin, Bohemia	4·2	Do. do. do.
Vichy, France (105° F.)	5·1	Do. do. do.
Neuenahr, Rhineland (92°–97° F.)	1·0	Mucous catarrh; diabetes specially.
La Malou, France (97° F.)	—	Do.; sedative effect on nervous system.
Vidago, Portugal	—	Do., gout, urinary affections—"The Portuguese Vichy."

CLASS II.—*With Chloride of Sodium varying from 4·3 to 1 in amount.*

Locality.	Height in Ft.	Temp. ° Fahr.	Carb. Soda.	Therapeutic Uses.
Luhatschowitz, Moravia	1600	—	8·4	Springs rich both in carb. soda and chl. sodium.
Tönnistein, Rhine Valley	—	—	2·5	Light antacid tonic to stomach.
Ems, Nassau	—	85–115	2·0	Special in female complaints and mucous membrane.
Ischia, Italy	—	up to 170	2·0	Specially rheumatism and female complaints.
Royat, Auvergne	1400	80–95	1·3	Do. and some skin affections.
Mont Dore, do.	3300	100–114	—	Asthma, chronic laryngitis.
Bourboule, do.	2800	107–125	—	Scrofula, rachitis, cutaneous affections.

CLASS III.—*With Sulphate of Soda varying from 5·2 to 2 in amount, and Carbonate of Soda varying from 3·55 to 0·51 in amount.*

Locality.	Height in Ft.	Therapeutic Uses.
Elster, Saxony	1460	Action on abdominal organs, female complaints.
Marienbad, Bohemia	1012	Do.; special use in obesity.
Franzensbad, do.	1293	Do.; specially a ladies' bath.
Tarasp, Lower Engadine	4000	Powerful action on abdominal viscera.
Carlsbad, Bohemia (121°–164° F.)	1200	Gout, liver affections, biliary and renal calculi, diabetes.

Two other classes of waters demand a few words of notice. The French have much faith in the presence of minute quantities of arsenic in some of their springs, and trace arsenical effects in those who drink them, and some French authors have established a class of *arsenical* waters. Bourboule in Auvergne is the strongest of them, and is said to contain $\frac{1}{12}$th of a grain of arseniate of soda in 7 oz. of water. Baden-Baden, according to Bunsen's latest analysis, has a right to be considered an arsenical water. It is, however, extremely doubtful whether the small amounts of arseniate of soda which have been detected, accompanied as they are by preponderating amounts of other salts, have any actual operation on the system. The following are among the most noted springs:

Bourboule, Mont Dore, Royat, Salies (Bigorres), Plombières, Baden-Baden.

Of late years *lithium* has been discovered in the waters of Baden-Baden; and various other places boast of the amount of that substance in their springs. Indeed a new bath has been established at Assmannshausen on the Rhine in consequence of the discovery of a weak alkaline spring containing some lithium. Not very much is known of the action of lithium in ordinary medicine, and it undoubtedly does not exist in medicinal doses even in the strongest springs. Among these springs are those of Baden-Baden, Assmannshausen, Elster, Royat, Ballston Spa, and Saratoga (U.S.).

	Designation and Locality.	Therapeutic Application.
Indifferent (Thermal).	Lebanon, Columbia co., N.Y. (73° F.)	
	Healing, Bath co., Va. (88° F.)	Scrofulous ulcers and ophthalmia, ozoena, chronic diarrhoea and dysentery, secondary and tertiary syphilis.
	Warm, Bath co., Va. (98° F.)	Chronic and subacute rheumatism, gout, neuralgia, nephritic and calculous diseases.
	Hot, Bath co., Va. (110° F.)	Chronic rheumatism, gout, diseases of liver, neuralgia, contractions of joints.
	Paso Robles, San Luis Obispo co., Cal. (122° F.)	
	Hot, Garland co., Ark. (93–150° F.)	Dartrous diseases of skin, functional diseases of uterus, chronic mercurial and lead poisoning.
Calcareous and Earthy.	Gettysburg, Adams co., Penn.	Calculus, gravel, catarrh of stomach or bladder, dyspepsia.
	Sweet, Monroe co., W. Va. (74° F.)	Gravel, dyspepsia (diuretic, diaphoretic).
	Berkeley, Morgan co., W. Va. (74° F.)	Neuralgia (restorative).
	Alleghany, Montgomery co., Va.	Purgative, diuretic.
	Bethesda, Waukesha co., Wis.	Diabetes mellitus, gravel, inflammation of bladder, dropsy, albuminuria (diuretic).
Sulphur.	Lower Blue Lick, Nicholas co., Ky.	Aperient and alterative.
	Sharon, Schoharie co., N.Y.	Do. do.
	White Sulphur, Greenbrier co., Va.	Dartrous skin diseases, diseases of the bladder, jaundice, dyspepsia.
	Salt Sulphur, Monroe co., W. Va.	Do.; scrofula and syphilis.
Epsom Salt.	Bedford, Bedford co., Penn.	Anaemia, gravel, calculus (strongly diuretic).
Common Salt.	St Catharines, Ontario, Canada	Rheumatism, gout, scrofula, neuralgia.
	Caledonia, Ontario, Canada	Rheumatism, gout.
	Hathorne, Saratoga, N. Y.	Dyspepsia, jaundice, abdominal plethora.
	Ballston, Saratoga co., N. Y.	Do. do. do.
Iron.	Oak-Orchard Acid, Genesee co., N. Y.	Ulcers, diseases of the skin, passive haemorrhages, atonic diarrhoea (has 10 grains of free sulphuric acid in the pint).
	Rawley, Rockingham co., Va.	Chlorosis and anaemia generally; tonic.
	Sweet Chalybeate, Alleghany co., Va.	Do. do. do.
	Rockbridge Alum, Rockbridge co., Va.	Scrofula, chronic diarrhoea.
	Cooper's Well, Hinds co., Miss.	Anaemia, chlorosis, chronic diarrhoea, dropsy.
Glauber Salt.	Crab Orchard, Lincoln co., Ky.	
	Midland, Midland co., Mich.	
Alkaline.	Bladen, Choctaw co., Ala. (carbonated alkaline)	
	Congress, Santa Clara co., Cal. (saline-alkaline)	
	St Louis, Gratiot co., Mich. (simple alkaline)	Dyspepsia, neuralgia, chronic and subacute rheumatism.

American Mineral Waters.—The number of springs in the United States and Canada to which public attention has been called on account of their supposed therapeutic virtues is very large, amounting in all to more than three hundred. Of this number comparatively few are in Canada, and of these not more than six (St Catharines, Caledonia, Plantagenet, Caxton, Charlottesville and Sandwich) have attained general celebrity. The first three belong to the saline class, the Caxton is alkaline-saline, and the last two are sulphur waters. The St Catharines is remarkable for the very large amounts of sodium, calcium and magnesium chlorides which it contains, its total salts (450 grains in the pint) being more than three times the quantity contained in the brine-baths of Kreuznach in Prussia. The Charlottesville and Sandwich springs likewise surpass the noted sulphur-waters of Europe in their excessive percentages of sulphuretted hydrogen, the former containing more than 3 and the latter 4·72 cub. in. of this gas in the pint.

The mineral springs in the United States are very unequally distributed, by far the larger number of those which are in high medical repute occurring along the Appalachian chain of mountains, and more especially on or near this chain where it passes through the States of Virginia, West Virginia and New York. The Devonian and Silurian formations which overlie the Eozoic rocks along the course of the Appalachian chain have been greatly fissured—the faulting of the strata being in some places of enormous magnitude—by the series of upheavals which gave rise to the many parallel mountain ridges of the Appalachians. In many places the springs occur directly along the lines of fault. The various classes of mineral waters are likewise very unequally represented, the alkaline springs, and those containing Glauber and Epsom salts, being much inferior to their European representatives. On the other hand, the very numerous and abundant springs of Saratoga compare very favourably with the Selters and similar saline waters, and among the many American chalybeate springs the subclass represented by the Rockbridge Alum is unequalled in regard to the very large percentages of alumina and sulphuric acid which it contains. Besides its greater amount of mineral constituents (135 grains per pint), the Ballston spring surpasses the similar saline waters of Homburg, Kissingen, Wiesbaden and Selters, in its percentage of carbonic acid (53 cub. in.). It is also remarkable for the very large proportion of carbonate of lithia, amounting to 0·701 grains. Thermal springs are specially numerous in the territories west of the Mississippi and in California. Those in the east mostly occur in Virginia along the southern portion of the Appalachian chain; in the middle and New England States Lebanon is the only important thermal spring. Subjoined is a list of thirty American springs, the design being to represent as many of the more noted spas as possible, while at the same time enumerating the best representatives of the classes and subclasses into which mineral waters are divided according to the German method of classification.

MINERVA, an Italian goddess, subsequently identified with Athena. She presided over all handicrafts, inventions, arts and sciences. Her oldest sanctuary at Rome was in the temple built by Tarquin on the Capitol, where she was worshipped with Jupiter and Juno. She had also a temple on the Aventine, which was the meeting-place for dramatic poets and actors, whose organization into gilds under her patronage dated from the time of Livius Andronicus (*q.v.*). The dedication day of the temple was the 19th of March, the great festival of Minerva, called *quinquatrus*, because it fell on the fifth day after the ides. All the schools had holidays at this time, and the pupils on reassembling brought a fee (*minerval*) to the teachers. In every house also the *quinquatrus* was a holiday, for Minerva (like Athena Erganē) was patron of the women's weaving and spinning and the workmen's craft. At a later time the festival extended over five days, the last four being chiefly occupied with gladiatorial shows—because Minerva was the goddess of war (Ovid, *Fasti*, iii. 809–834; Juvenal x. 115, with Mayor's note). The erection of a temple to her by Pompey out of the spoils of his eastern conquests shows that she was the bestower of victory, like Athena Nikē, and the dedication of a vestibule in the senate house by Augustus recalls Athena the goddess of counsel (βουλαία). Under Domitian, who claimed her special protection, the worship of Minerva attained its greatest vogue in Rome. The emperor Hadrian founded an educational institution, named after her the Athenaeum. The 23rd of March had always been the day of the *tubilustrium*, or purification of the trumpets used in the sacred rites, so that the ceremony came to be on the last day of Minerva's festival, but it is very doubtful whether it was really connected with her. There was another temple of Minerva on the Caelian Hill, where she was worshipped under the name of Capta, the "captive," the origin of which is unknown. Here a festival called the lesser *quinquatrus* was celebrated on the 13th–14th of June, chiefly by the flute-players (Livy ix. 30; Ovid, *Fasti*, vi. 651). As the Romans learnt the use of the flute from the Etruscans, the fact of Minerva being the patron goddess of flute-players is in favour of her Etruscan origin, although it may merely be a reminiscence of the Greek story which attributed the invention of the flute to Athena. A carved image of the goddess called the Palladium, said to have been brought from Troy to Lavinium, and thence to Rome by the family of the Nautii, was kept in the temple of Vesta and carefully guarded as necessary to the prosperity of the city. The older form of the name Minerva is Menerva (=Menes-va, Gr. μένος); it probably means "thinker."

MINGHETTI, MARCO (1818–1886), Italian economist and statesman, was born at Bologna on the 18th of November 1818. In 1846 he signed the petition to the Conclave for the election of a Liberal pope, and was appointed member of the state council summoned to prepare the constitution for the papal states. With Antonio Montanari and Rodolfo Audinot he founded at Bologna a paper, *Il Felsineo*. In the first constitutional cabinet, presided over by Cardinal Antonelli, Minghetti held the portfolio of public works, but after the allocution by Pius IX. against the Italian war of independence he resigned, and joined the Piedmontese army as captain on the general staff. Returning to Rome in September 1848, he refused to form a cabinet after the assassination of Pellegrino Rossi, and spent the next eight years in study and travel. Summoned to Paris by Cavour in 1856 to prepare the memorandum on the Romagna provinces for the Paris congress, he was in 1859 appointed by Cavour secretary-general of the Piedmontese Foreign Office. In the same year he was elected president of the assembly of the Romagna after the rejection of pontifical rule by those provinces, and prepared their annexation to Piedmont. Appointed Piedmontese minister of the interior, he resigned office shortly after Cavour's death, but was subsequently chosen to be minister of finance by Farini, whom he succeeded as premier in 1863. With the help of Visconti-Venosta he concluded (Sept. 15, 1864) the "September Convention" with France, whereby Napoleon agreed to evacuate Rome, and Italy to transfer her capital from Turin to Florence. The convention excited violent opposition at Turin, in consequence of which Minghetti was obliged to resign office. He took little part in public life until 1869, when he accepted the portfolio of agriculture in the Menabrea Cabinet. Both in and out of office he exercised his influence against an Italo-French alliance and for an immediate advance upon Rome, and in 1870 was sent to London and Vienna by the Lanza-Sella Cabinet to organize a league of neutral powers on the outbreak of the Franco-Prussian War. In 1873 he overthrew the Lanza-Sella Cabinet and regained the premiership, which, with the portfolio of finance, he held until the fall of the Right from power on the 18th of March 1876. During his premiership he inaugurated the *rapprochement* between Italy, Austria and Germany, and reformed the naval and military administration; and before his fall he was able, as finance minister, to announce the restoration of equilibrium between expenditure and revenue for the first time since 1860. After the advent of the Left, Minghetti remained for some years in Opposition, but towards 1884 joined Depretis in creating the "Trasformismo," which consisted in bringing Conservative support to Liberal cabinets. Minghetti, however, drew from it no personal advantage, and died at Rome on the 10th of December 1886 without having returned to power.

His writings include: *Della economia pubblica e delle sue attinenze con la morale e col diritto* (Bologna, 1859), and *La Chiesa e lo Stato* (Milan, 1878).

MINGRELIA, a former principality of Transcaucasia, which became subject to Russia in 1804, and since 1867 has belonged to the government of Kutais. The country corresponds to the ancient Colchis; and Sukhum Kaleh on the Black Sea coast, which was the capital under the Dadian dynasty (1323–1694), is to be identified with the ancient Dioscurias, a colony of Miletus. The Mingrelians, who are closely akin to the Georgians, numbered 241,000 in 1902, and belong to the Orthodox Greek Church (see further KUTAIS and CAUCASIA).

MINIATURE. The word "miniature," derived from the Latin *minium*, red lead, has been technically employed, in the first instance, to describe a picture in an ancient or medieval manuscript; the simple decoration of the early codices having been "miniated" or delineated with that pigment. The generally small scale of the medieval pictures has led secondly to a pseudo-etymological confusion of the term with "minuteness" and to its application to "paintings in little"; it is now used mainly in this sense, and is ordinarily applied to a painting on a very small scale, usually a portrait, and by analogy to anything on a very small scale.

1. *Miniatures in Ancient and Medieval MSS.*—The part played by the miniature in the scheme of the ornamentation of MSS., in the early centuries of the Christian era and in the middle ages, is dealt with in the article on ILLUMINATED MSS. In the present article will be discussed the development and changes which it underwent, in different ages and in different countries, both in its technical treatment and in its leading characteristics. The subject divides itself into two distinct portions, the classical and the medieval, between which there lies the great separating space of the early middle ages, which affords but scanty material to connect them. When, however, we have advanced into the middle ages, we are no longer at a loss; and we can follow the later development of the miniature through all its changes in the various schools of western Europe down to its transition into the modern picture.

The importance of the study of the miniature has perhaps hardly received in the past the recognition which it merits. The history of painting cannot be perfectly understood without a knowledge of the rise and progress of the art of miniature-painting in MSS; and examples of the art still survive in an abundance which frescoes and paintings in the large cannot rival. Modern methods of photography have brought within the reach of the student material which in earlier generations was not accessible; and consequently a juster conception can be formed of the position which the miniature holds in the history of art than was possible before.

The earliest examples that have descended to us are closely connected in style and treatment with the pictorial art of the later Roman classical period. In fact they are separated from that period by only two or three centuries, and they still follow its traditions. The oldest specimens of all are the series of coloured drawings or miniatures cut from an illustrated MS.

of the *Iliad* and now in the Ambrosian Library at Milan, which there is good reason for placing as early as the 3rd century. In these pictures there is a considerable variety in the quality of the drawing, but there are many notable instances of fine figure-drawing, quite classical in sentiment, showing that the earlier art still exercised its influence. Such indications, too, of landscape as are to be found are of the classical type, not conventional in the sense of medieval conventionalism, but still attempting to follow nature, even if in an imperfect fashion; just as in the Pompeian and other frescoes of the Roman age.

Of even greater value from an artistic point of view are the miniatures of the Vatican MS. of Virgil, known as the "Schedae Vaticanae," of the 4th century. They are in a more perfect condition and on a larger scale than the Ambrosian fragments, and they therefore offer better opportunity for examining method and technique. The drawing is quite classical in style, and the idea is conveyed that the miniatures are direct copies from an older series. The colours are opaque: indeed, in all the miniatures of early MSS. the employment of body colour was universal. The method followed in placing the different scenes on the page is highly instructive of the practice followed, as we may presume, by the artists of the early centuries. It seems that the background of the scene was first painted in full, covering the whole surface of the page; then, over this background were painted the larger figures and objects; and over these again the smaller details in front of them were superimposed. Again, for the purpose of securing something like perspective, an arrangement of horizontal zones was adopted, the upper ones containing figures on a smaller scale than those below.

It was reserved for the Byzantine school to break away more decidedly from the natural presentment of things and to develop convention. Yet in the best early examples of this school the classical sentiment still lingers, as the relics of the miniatures of the Cottonian Genesis, in the British Museum, and the best of the miniatures of the Vienna Dioscorides testify; and in the miniatures of the later Byzantine MSS., which were copied from earlier examples, the reproduction of the models is faithful. But on comparing the miniatures of the Byzantine school generally with their classical predecessors, one has a sense of having passed from the open air into the cloister. Under the restraint of ecclesiastical domination Byzantine art became more and more stereotyped and conventional. The tendency grows to paint the flesh-tints in swarthy hues, to elongate and emaciate the limbs, and to stiffen the gait. Browns, blue-greys and neutral tints are in favour. Here we first find the technical treatment of flesh-painting which afterwards became the special practice of Italian miniaturists, namely the laying on of the actual flesh-tints over a ground of olive, green or other dark hue. Landscape, such as it was, soon became quite conventional, setting the example for that remarkable absence of the true representation of nature which is such a striking attribute of the miniatures of the middle ages.

And yet, while the ascetic treatment of the miniatures obtained so strongly in Byzantine art, at the same time the Oriental sense of splendour shows itself in the brilliancy of much of the colouring and in the lavish employment of gold. In the miniatures of Byzantine MSS. are first seen those backgrounds of bright gold which afterwards appear in such profusion in the productions of every western school of painting.

The influence of Byzantine art on that of medieval Italy is obvious. The early mosaics in the churches of Italy, such as those at Ravenna and Venice, also afford examples of the dominating Byzantine influence. But the early middle ages provide but few landmarks to guide the student; and it is only when he emerges into the 12th century, with its frescoes and miniatures still bearing the impress of the Byzantine tradition, that he can be satisfied that the connexion has always existed during the intervening centuries.

When we turn to the farther-west of Europe, there also we find under the Carolingian monarchs a school of painting obviously derived from classical models, chiefly of the Byzantine type, but whether derived directly from the East, or, what is more probable, transmitted through Italian channels, must remain doubtful. The interest of that school for our present purpose is that it was the parent of the later miniature-painting in the countries of the West. For in the native schools of those countries decoration only was the leading motive. In the MSS. of the Merovingian period, in the school which connected Frankland and northern Italy, and which is known as Lombardic or Franco-Lombardic, in the MSS. of Spain, in the productions of the Celtic school of our own islands, figure-drawing was scarcely known, and where it was practised it was of a barbarous character, serving rather as a feature of decoration than as a representation of the human form. Hence in those native schools the miniature, in its true sense of a picture, may be regarded as non-existent.

From these native schools we exclude the Anglo-Saxon school, developed especially at Canterbury and Winchester, which probably derived its characteristic free-hand drawing from classical Roman models, scarcely influenced by the Byzantine element. The highest qualities of the miniatures of the 10th and 11th centuries of this school lie in fine outline drawing, which had a lasting influence on the English miniature of the later centuries. But the southern Anglo-Saxon school rather stands apart from the general line of development of the western medieval miniature. How far it was affected by Continental influence will be presently noticed.

Turning to the productions of the Carolingian school, which owed its origin to the encouragement of Charlemagne, it is seen that the miniature appears in two forms. First, there is the truly conventional miniature following the Byzantine model, the subjects being generally the portraits of the Evangelists, or portraits of the emperors themselves: the figures stiff and formal; the pages brilliantly and often coarsely coloured and gilded, generally set in architectural surroundings of a fixed type, and devoid of landscape in the real sense of the word. On the other hand, there is also the miniature in which there is an attempt at illustration, as, for example, the depicting of scenes from Bible history. Here there is more freedom; and we trace the debased classical style which copies Roman, as distinguished from Byzantine, models. The figure-drawing is sufficiently clumsy, but the type is Roman, or debased Roman, and the costumes are clearly derived from the same source. Here, too, there is a better attempt at landscape, which is not of the absolutely conventional deadness of the Carolingian-Byzantine type. But this second style of illustrative miniature appears only occasionally. The other was the characteristic miniature of the Carolingian school, and, accompanied as it was with profuse decoration in border and initial, it set the pattern for the later Continental schools of the West.

The influence which the Carolingian school exercised on the miniatures of the southern Anglo-Saxon artists shows itself in the extended use of body-colour and in the more elaborate employment of gold in the decoration. Such a MS. as the Benedictional of Aethelwold, bishop of Winchester, 963 to 984, with its series of miniatures drawn in the native style but painted in opaque pigments, exhibits the influence of the foreign art. But the actual drawing remained essentially national, marked by its own treatment of the human figure and by the peculiar disposition of the drapery with fluttering folds. Its fault was over-refinement, tending to an affected exaggeration and disproportion of the limbs. With the Norman Conquest this remarkable native school passed away.

The period immediately succeeding the Carolingian school in western Europe was one of extreme decadence in the miniatures of MSS. In the 10th and 11th centuries they were mere lifeless copies of earlier types. But with the awakening of art in the 12th century the decoration of MSS. received a powerful impulse. Although the artist of the time excels in the border and the initial, still in the miniature also there is vigorous drawing, with bold sweeping lines and careful study of the draperies. The artist now grows more practised in figure-drawing, and while there is still the tendency to repeat the same subjects in the same conventional manner, individual effort produced in this century many miniatures of a very noble character. The Norman Conquest had brought England directly within the fold of Continental art; and now began that grouping of the French and the English and the Flemish schools, which, fostered by growing intercourse and moved by common impulses, resulted in the magnificent productions of the illuminators of north-western Europe from the latter part of the 12th century onwards. But of natural landscape there is nothing, unless rocks and trees of a stereotyped character can be so regarded. Hence the background of the miniature of the 12th and immediately succeeding centuries became the field for decoration to throw into stronger relief the figures in the scene. And thus arose the practice of filling in the entire space with a sheet of gold, often burnished: a brilliant method of ornament which we have already seen practised in the Byzantine school. We have also to notice the conventional treatment of the sacred figures, which continue henceforward, from a sense of veneration, to be clad in the traditional robes of the early centuries, while the other figures of the scene wear the ordinary dress of the period.

It will be convenient, at this point, to follow the development of the miniature in the northern schools of England and France and the Low Countries, occasionally glancing at Germany, during the next three centuries, and to leave aside for the moment consideration of the Italian school and the schools allied therewith.

Entering the 13th century, we reach the period when the miniature may be said to justify the modern false etymology which has connected the title with minuteness. The broad, bold style of the 12th century gives place to the precise and minute. Books in general exchanged their form from the large folio to the octavo and smaller sizes. There was a greater demand for books; and vellum was limited in quantity and had to go further. The handwriting grew smaller and lost the roundness of the 12th century. Contractions and abbreviations in the texts largely increased in number. Everywhere there is an effort to save space. And so with the miniature. Figures were small, with delicate strokes in the features and with neat slim bodies and limbs. The backgrounds blaze with colour and burnished gold; and delicate diaper patterns of alternate gold and colour abound. Frequently, and especially in English MSS., the drawings are merely tinted or washed with transparent colours. In this century, too, the miniature invades the initial. Whereas in the earlier periods bold flowering scrolls are the fashion, now a little scene is introduced into the blank spaces of the letter. To compare the work of the three schools, the drawing of the English miniature, at its best, is perhaps the most graceful; the French is the neatest and the most accurate; the Flemish, including that of western Germany, is less refined and in harder and stronger lines. As to colours, the English artist affects rather lighter tints than those of the other schools: a partiality is to be observed for light green, for grey-blue, and for lake. The French artist loved deeper shades, especially ultramarine. The Fleming and the German painted, as a rule, in less pure colours and inclined to heaviness. A noticeable feature in French MSS. is the red or copper-hued gold used in their illuminations, in strong contrast to the paler metal of England and the Low Countries.

It is remarkable how the art of the miniature throughout the 13th century maintains its high quality both in drawing and colour without any very striking change. Throughout the century the Bible and the Psalter were in favour; and naturally the same subjects and the same scenes ran through the period and were repeated by artist after artist; and the very character of those sacred books would tend to restrain innovation. But towards the close of the period such secular works as the romances were growing in popularity, and afforded a wider field for the invention of the illustrating artist. Therefore with the opening of the 14th century a palpable change of style supervenes. We pass to more flowing lines; not to the bold sweeping strokes and curves of the 12th century, but to a graceful, delicate, yielding style which produced the beautiful swaying figures of the period. In fact the miniature now begins to free itself from the rôle of an integral member of the decorative scheme of illumination and to develop into the picture, depending on its own artistic merit for the position it is to hold in the future. This is shown by the more prominent place that the miniature now assumes, and by its growing independence of the decorative border and initial. But, at the same time, while the miniature of the 14th century thus strives to dissociate itself from the rest of the illuminated details of the MS., within itself it flourishes in decoration. Besides the greater elasticity of the figure-drawing, there is a parallel development in the designs of the backgrounds. The diapers become more elaborate and more brilliant; the beauty of the burnished gold is enhanced by the stippled patterns which are frequently worked upon it; the gothic canopies and other architectural features which it became the practice to introduce naturally followed the development of the architecture of the period. In a word, the great expansion of artistic sentiment in decoration of the best type, which is so prominent in the higher work of the 14th century, is equally conspicuous in the illuminated miniature.

In the early part of the century, English drawing is very graceful, the figures bending with a waving movement which, if they were not so simple, would be an affectation. Both in the outline specimens, washed with transparent colour, and in the fully painted examples, the best English work of this time is unsurpassed. French art still maintains its neat precision, the colours more vivid than those of England and the faces delicately indicated without much modelling. The productions of the Low Countries, still keeping to the heavier style of drawing, appear coarse beside the works of the other schools. Nor does German miniature art of this period hold a high position, being generally mechanical and of a rustic character. As time advances the French miniature almost monopolizes the field, excelling in brilliancy of colouring, but losing much of its purity of drawing although the general standard still remains high. The English school gradually retrogrades and, owing no doubt to political causes and to the wars with France, appears to have produced no work of much value. It is only towards the end of the century that there is a revival.

This revival, which is referred to in the article on ILLUMINATED MSS., has been attributed, with some reason, to a connexion with the flourishing school of Prague—a school which in the scheme of colouring suggests a southern influence—following on the marriage of Richard II. with Anne of Bohemia in 1382. The new style of English miniature painting is distinguished by richness of colour, and by the careful modelling of the faces, which compares favourably with the slighter treatment by the contemporary French artists. Similar attention to the features also marks the northern Flemish or Dutch school at this period and in the early 15th century; and it may therefore be regarded as an attribute of Germanic art as distinguished from the French style. The promise of the new development in English miniature painting, however, was not to be fulfilled. In the first quarter of the 15th century, examples of great merit were produced, but at a standstill in drawing and fettered by medieval convention. The native art practically came to a close about the middle of the century, just when the better appreciation of nature was breaking down the old conventional representation of landscape in European art, and was transforming the miniature into the modern picture. Whatever miniature painting was to be produced in England after that time was to be the work of foreign artists or of artists imitating a foreign style. The condition of the country during the Wars of the Roses sufficiently accounts for the abandonment of art. Thus the history of the miniature in the 15th century must be sought in the manuscripts of the Continental schools.

First we have to consider northern France and the Low Countries. As it passes out of the 14th and enters the 15th century, the miniature of both schools begins to exhibit greater freedom in composition; and there is a further tendency to aim rather at general effect by the colouring than neatness in drawing. This was encouraged by the wider field opened to the miniaturist. Books of all kinds were illustrated, and sacred books, Bibles and Psalters and liturgical books, were no longer the chief, if not the only, MSS. which were illuminated. And yet there was one class of MSS. which came into the greatest prominence and which was at the same time liturgical. This was the *Horae*, or Hours of the Virgin, &c., devotional books for individual use, which were multiplied in vast numbers and contained some of the finest work of the miniaturists. The decoration of these little volumes escaped in great measure from the conventional restraints which their religious character might have imposed. Futhermore, the demand for illuminated MSS. had by this time established a regular trade; and their production was not confined, as formerly, to the cloister with its narrow and limited views.

Early in the century the old conventional treatment of landscape still held its own; nor did the diapered and gilded background pass out of use. Indeed, in some of the finest French specimens of the time the diapered patterns are more brilliant than ever. But natural scenery in the second quarter of the century asserts itself more decidedly, although with faults in perspective. It was not until another generation had arisen that there was a true appreciation of the horizon and of atmospheric effect.

The miniatures of the French and Flemish schools run fairly parallel for a time, but after the middle of the century national characteristics become more marked and divergent. The French miniature began to deteriorate, though some very fine examples were produced by the more gifted artists of the school. The figure-drawing was more careless, and the painting tended to hardness without depth, which the artist endeavoured to relieve by an excess of gilt shading. The close of the century brought with it the end of the French miniature; for the extravagant productions of the 16th century cannot be counted as worthy of consideration.

The French miniature went down before the Flemish school, which in the latter part of the 15th century attained to its highest excellence. The Flemish miniature affected extreme softness and depth of colour; also an ever-increasing carefulness in the treatment of details, of the draperies, of the expression of the features: the Flemish type of the Virgin's face, for example, with its full, high forehead, can never be mistaken. In the best Flemish miniatures of the period the artist succeeds in presenting a wonderful softness and glow of colour; nor did the high standard cease with the 15th century, for many excellent specimens still remain to attest the favour in which it was held for a few decades longer.

In the foregoing remarks what has been said in regard to the careful treatment of details applies still more to the miniatures executed in *grisaille*, in which the absence of colour invited an even stronger accentuation of that treatment. This is perhaps most observable in the *grisaille* miniatures of northern Flanders, which often suggest, particularly in the strong angular lines of the draperies, a connexion with the art of the wood-engraver.

The Flemish miniature did not, however, hold the favour of western Europe without a rival. That rival had arisen in the south, and had come to perfection concurrently with the miniature of the Low Countries in the 15th century. This was the Italian miniature; and the history of its development now claims a brief notice. We return to the 13th century, where we suspended examination of the work of the school of the miniature painters of Italy; but we are not in a position, from lack of material, to follow so closely the development of the Italian miniature. Yet there is enough to show that it passed through the same stages as the miniatures of England and France and the Low Countries. Intercommunication between the countries of Europe was too well established for the case to be otherwise. In Italian MSS. of the normal type the influence of Byzantine art is very manifest during the 13th and 14th centuries. The old system of painting the flesh tints upon olive green or some similar pigment, which is left exposed on the lines of the features, thus obtaining a swarthy complexion, continued to be practised in a more or less modified form into the 15th century. As a rule, the pigments used are more opaque than those employed in the northern schools; and the artist trusted more to colour alone to obtain the desired effect than to the mixture of colour and gold which gave such brilliant results in the diapered patterns of France. The vivid scarlet of the Italian miniaturists is peculiarly their own. The figure-drawing does not bear comparison with the contemporary art of English and French MSS., the human form being often stunted and thick-set. In general, the Italian miniature, before its great expansion in the 14th century, is far behind the miniatures of the north. But with the 15th century, under the influence of the Renaissance, it advanced into the front rank and rivalled the best work of the Flemish school. The use of thicker pigments enabled the miniaturist to obtain the hard and polished surface so characteristic of his work, and to maintain sharpness of outline, without losing the depth and richness of colour which compare with the same qualities in the Flemish school.

The Italian style was followed in the MSS. of Provence in the 14th and 15th centuries. It had its effect, too, on the school of northern France, by which it was also influenced in turn. In the MSS. of southern Germany it is also in evidence. But the principles which have been reviewed as guiding the development of the miniature in the more important schools apply equally to all. Like the miniature of the Flemish school, the Italian miniature was still worked to some extent with success, under special patronage, even in the 16th century; but with the rapid displacement of the manuscript by the printed book the miniaturist's occupation was brought to a close.

For *Authorities* see under Illuminated MSS. (E. M. T.)

2. *Miniatures as separate Small Pictures.*—In Europe the later development of the miniature, applied almost exclusively to portraits, is to a large extent English, and the greater number of the chief masters in the art have been Englishmen or have lived in England. Several great portrait painters are said to have worked occasionally in miniature, and there are paintings, small in size attributed with good reason to Holbein, Antonio Moro, John Shute, Cleef, Stretes, Teerlinck, Zucchero, John and T. Betts, and with less probability even to Van Dyck. There is a fine signed work by Shute (see Lomazzo's *Trattato dell' arte della pittura*, trans. Heydock, 1598) in the Pierpont Morgan collection; examples by Betts at Montagu House and Madresfield Court, and portraits, by Lavina Teerlinck in the collections of Mr George Salting and Mr J. Pierpont Morgan.

The first portrait miniaturist about whom anything definite is known was Nicholas Hilliard (*c.* 1547–1619), whose work partakes of the characteristics of illuminated manuscripts. The colours are opaque; gold is used to heighten the effect; while the paintings are on card. They are often signed, and have frequently also a Latin motto upon them. It has recently been proved that Hilliard worked for a while in France, and he is probably identical with the painter alluded to in 1577 as "Nicholas Belliart." Nicholas Hilliard was succeeded by his son Lawrence (d. 1640), some works by whom are in the Pierpont Morgan and Madresfield Court collections. His technique was similar to that of his father, but bolder, and his miniatures richer in colour. Isaac and Peter Oliver succeeded Hilliard. Isaac (*c.* 1567–1617) is said to have been the pupil of Hilliard and Zucchero. Peter (1594–1647) was the pupil of Isaac. The two men were the earliest to give roundness and form to the faces they painted. They signed their best works in monogram, and painted not only very small miniatures, but larger ones measuring as much as 10 in. by 9 in. They copied for Charles I. on a small scale many of his famous pictures by the old masters. Several of these copies are at Windsor and at Montagu House. At about the same date Gerbier, Poelemberg, Jamesone, Penelope Cleyn and her brothers, were workers in the art. John Hoskins (d. 1664) was the master of Samuel Cooper, the greatest English miniaturist. The work of Cooper can best be studied in the collection at Ham House. He was followed by a son of the same name, who was known to have been living in 1700, since a miniature signed by him and bearing that date is in the Pierpont

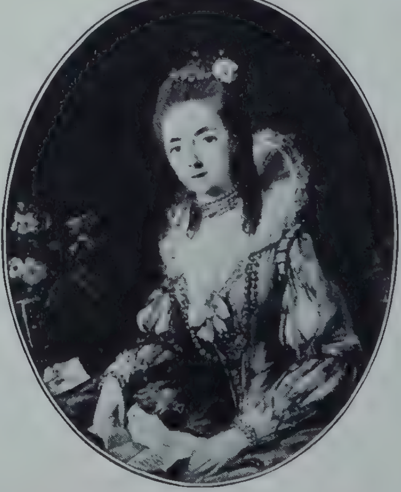
FIG. 9.—LADY. By HORACE HONE.



Collection of the King of Sweden.

FIG. 10.—THE COUNTESS D'EGMONT. By P. A. HALL

Nos. 2, 3, 4, 5, 6 and 8 are all from the Collection of Mr J. Pierpont Morgan.

Morgan collection. It represents the duke of Berwick. Samuel Cooper (1609–1672) was a nephew of Hoskins. He spent much of his time in Paris and Holland, and very little is known of his career. His work has a superb breadth and dignity, and has been well called "life-size work in little." His portraits of the men of the Puritan epoch are remarkable for their truth to life and strength of handling. He painted upon card, chicken skin and vellum, and on two occasions upon thin pieces of mutton bone. The use of ivory was not introduced until long after his time. His work is frequently signed with his initials, generally in gold, and very often with the addition of the date. Flatman (d. 1688); Alexander Cooper (d. 1660), who painted a series of portraits of the children of the king and queen of Bohemia, now belonging to the German emperor, and several of whose best miniatures are in the collections of the queen of Holland and the king of Sweden; David des Granges (1611–1675) whose work can be seen at Ham House and Windsor Castle; R. Gibson (1615–1690); Mrs Rosse, his daughter, who so cleverly imitated the work of Samuel Cooper, and Charles and Mary Beale, deserve notice at this period. They are followed by such artists as Lawrence Crosse (d. 1724), Gervase Spencer (d. 1763), Lens, Nathaniel Hone and Jeremiah Meyer, the latter two notable in connexion with the foundation of the Royal Academy. The workers in black lead (plumbago, as it was called at that time) must not be overlooked, especially David Loggan, Faithorne, White, Forster and Faber. They drew with exquisite detail and great effect on paper or vellum. The 18th century produced a great number of miniature painters, of whom Richard Cosway (1742–1821) is the most famous. His works are of great beauty, and executed with a dash and brilliance which no other artist equalled. His best work was done about 1799. His portraits are generally on ivory, although occasionally he worked on paper or vellum, and he produced a great many full-length pencil drawings on paper, in which he slightly tinted the faces and hands, and these he called "stayned" drawings. Cosway's finest miniatures are signed on the back; there is but one genuine signed on the face; very few bear even his initials on the front. George Engleheart (1750–1829) painted 4900 miniatures, and his work is stronger and more impressive than that of Cosway; it is often signed "E" or "G.E." Andrew Plimer (1763–1837) was a pupil of Cosway, and both he and his brother Nathaniel produced some lovely portraits. The brightness of the eyes, wiriness of the hair, exuberance of colour, combined with forced chiaroscuro and often very inaccurate drawing, are characteristics of Andrew Plimer's work. John Smart (1741–1811) was in some respects the greatest of the 18th-century miniaturists. His work excelled in refinement, power and delicacy; its silky texture and elaborate finish, and the artist's love for a brown background, distinguish it. Other notable painters were Ozias Humphry (1742–1810), Nixon (1741–1812), Shelley (*c.* 1750–1808), whose best pictures are groups of two or more persons, William Wood, a Suffolk artist (1768–1808), Edridge (1769–1821), Sullivan, Sheriff, Crosse, Bogle, Daye. In the 19th century J. C. D. Engleheart (1784–1862), nephew of George: Andrew Robertson (1777–1845), Beaumont, Behnes, Harlow, Heaphy and Mrs Mee must be mentioned. Sir Thomas Lawrence painted a few miniatures, and Raeburn some in his early days; but the art may be said to have died out with Sir William Ross, the Chalons and Newton, although some works by Landseer in this form are in existence, some small paintings of flowers by George Lance, and one portrait by Rossetti. Towards the end of the 19th century came a revival of miniature painting, but without producing any masters of the same calibre. Alyn Williams and Lloyd amongst Englishmen, J. W. von Rehling-Quistgaard, the talented Danish miniature painter, and Bess Norris, an Australian artist, deserve mention.

From about 1650 onwards many fine miniatures were executed in enamel. Petitot (1607–1691) was the greatest worker in this material, and painted his finest portraits in Paris for Louis XIV. His son succeeded him in the same profession. Other artists in enamel were Boit (d. 1727), Zincke (d. 1767), Hurter (1734–1790), Thouron (1737–1789), Liot, Prieur, Spicer, Dinglinger, Vouquer, Bain and Thienpondt. Many of these artists were either Frenchmen or Swiss, but most of them visited England and worked there for a while. The greatest English enamel portrait painter was Henry Bone (1755–1839), the finest of whose productions are now at Kingston Lacy. A great collection of his small enamel reproductions of celebrated paintings is in Buckingham Palace.

The earliest French miniature painters were Jean Clouet (d. *c.* 1540), his son François, Jean Fouquet, Jean Perreal and others; but of their work in portraiture we have little trace at the present day, although there are many portraits and a vast number of drawings attributed to them with more or less reason. The seven portraits in the manuscript of the *Gallic War* (Bibliothèque Nationale) are assigned to the elder Clouet; and to them may be added a fine work, in the Pierpont Morgan collection, representing the Maréschal de Brissac. Following these men we find the two Strèsors, St André, Cotelle and Massé; the fine draughtsmen Picart, Vauthier and Chéron; and then, later on, we know of miniatures by Largillière, Boucher, Nattier, Montpetit, Desfosses, Drouais, Charlier, Thouron, Perrin and Dubourg; but the greatest names are those of Hall the Swede, Dumont the Frenchman, and Füger the Austrian. The tiny pictures painted by the von Blarenberghe family are by many persons grouped as miniatures, and some of the later French artists, as Prud'hon, Constance Meyer and Dubois, executed miniature portraits, while others whose names might be mentioned were Werner (1637–1710), Rosalba (1675–1757), Chatillon, Pasquier, Marsigli, Garriot, Sicardi and Festa. The most popular artists in France, however, were Augustin (d. 1832) and Isabey (d. 1855). Their portraits of Napoleon and his court are exceedingly fine, and perhaps no other Frenchman painted miniatures so well as did Augustin. The Spanish painter Goya is known to have executed a few miniatures.

Miniatures are painted in oil, water-colour and enamel, but chiefly in water-colour. Many Dutch and German miniatures were painted in oil, and as a rule these are on copper; and there are portraits in the same medium, and often on the same material, attributed to many of the great Italian artists, notably those of the Bologna school. Samuel Cooper is said to have executed a few paintings in oil on copper, but we know little about the artists who prepared the numerous oil portraits in foreign collections.

The work of the 18th century on ivory is, of course, in water-colour. The use of ivory came into general adoption in the early part of the reign of William III., miniatures previous to that time having been painted on vellum, chicken-skin or cardboard, a few on the backs of playing cards, and many more on very thin vellum closely mounted on to playing cards.

The most important collections of miniatures in England in 1907 were those in the possession of the king, the duke of Buccleuch, Mr J. Pierpont Morgan, the duke of Rutland, the earls of Exeter, Ilchester, Dysart, Dartrey (notable for enamel work, some examples of which are of the greatest rarity) and Ancaster (especially notable for works by Cosway), of Earl Beauchamp, the late Baroness Burdett-Coutts, Sir Gardner Engleheart (remarkable for containing almost exclusively works by the Engleheart family), Lord Weardale, and Messrs Drake, Digby, Williams, Whitehead, and Usher of Lincoln. There is a remarkable collection, principally of works in enamel, in the University Gallery, Oxford, a few fine miniatures at South Kensington, and in the same museum in the Jones collection some splendid works by Petitot, and there are also some famous foreign portrait and picture miniatures in the Wallace Collection, Hertford House, London. The collection at the Louvre is of importance, especially as regards the works of Petitot; that belonging to the queen of Holland of very high merit, and includes some choice works by Holbein and Alexander Cooper; and there is also a very fine collection at Amsterdam, including some of the largest works by Samuel Cooper and the largest known by Hoskins; some very fine ones belong to the Crown of Sweden, and there is a superb but very mixed collection in Peter the Great's Gallery in St Petersburg, unfortunately in great confusion and needing rearrangement. Many fine miniatures, including some very scarce enamel work by Prieur, are at the Rosenborg Palace in Copenhagen; the German emperor and the Crown of Prussia both own some remarkable examples, and there are important collections at Vienna, Florence and Stockholm, and in private hands in Berlin, Moscow and Helsingfors.

Williamson, *History of Portrait Miniatures* (2 vols., folio, 1904), *Portrait Miniatures* (London, 1897); *Richard Cosway* (London, 1897); *George Engleheart* (London, 1902); *Andrew Plimer, &c.* (London, 1902); *How to Identify Miniatures* (London, 1904); *Richard Cosway* (London, 1905), and the privately printed catalogue of the *Pierpont Morgan Collection* (1906, 1907, 1908); *Les Émaux de Petitot du Louvre* (Paris, 1862–1864); catalogues of the Buccleuch Gallery, Welbeck Gallery, Ward Usher Collection, Bemrose Collection, Woburn Abbey Collection, all privately printed, the catalogue of the collection exhibited at South Kensington, and the privately issued catalogue at the Burlington Fine Arts Club, with illustrations. (G. C. W.)

MINIM (adapted from Lat. *minimus*, the smallest; a superlative formed from the Indo-Germanic root *min-*, small), the smallest possible part of a thing, a particle. In music the name "minim" (*nota minima*) was given by medieval musicians to a note whose value was half a semibreve. It was, as its name implies, the note of the shortest duration then in use. In modern music several notes of lesser value, as the "crotchet" and "quaver," have been added, and the minim is now about halfway in the scale of "values." According to Thomas Morley (*A Plaine and Easie Introduction to Practical Music*, 1597), its introduction into manuscript music is ascribed to Phillipus de Vitriaco, a musician of the 14th century.

In medicine a minim is the smallest fluid measure, being equal to one drop. Sixty minims make a fluid drachm.

For the religious Order known as "Minims" see FRANCIS OF PAOLA, ST.

MINING, the general term for the working of deposits of valuable mineral. The term[1] is not limited to underground operations, but includes also surface excavations, as in placer mining and open-air workings of coal and ore deposits by methods similar to quarrying, and boring operations for oil, natural gas or brine. Mining may be subdivided into the operations of prospecting or search for minerals, exploration and development, work preparatory to active operations, and working. The latter includes not only the actual excavation of the mineral, but also haulage and hoisting by which it is brought to the surface, timbering and other means of supporting the excavations, and the drainage and ventilation of mines. Finally, under the heads of administration, mine valuation, mining education, accidents, hygiene and mining law, will be discussed matters having important bearing on mining operations. Special methods of mining are dealt with in the separate articles on COAL, GOLD, and other minerals and metals. QUARRYING and ORE-DRESSING, which may be considered as branches of mining, are also discussed in separate articles.

Prospecting.—In the article on MINERAL DEPOSITS (*q.v.*) the distribution and mode of occurrence of the useful minerals and ores are fully discussed. The work of prospecting is usually left to adventurous men who are willing to undergo privation and hardship in the hope of large reward though the chances of success are small. The prospector is guided in his search by a knowledge of the geological conditions under which useful minerals occur. When the rocks are concealed by detrital material he looks for outcroppings on steep hillsides, on the crests of hills or ridges, in the beds of streams, in landslides, in the roots of overturned trees, and in wells, quarries, road-cuttings and other excavations. When the solid rock is not exposed the soil sometimes furnishes an indication of the character of the underlying rock. Sometimes the vegetation, shrubs, trees, &c., as characteristic of certain soils, may furnish evidence as to rock or minerals below. Search should be made in the beds of streams and on the hillsides for "float mineral" or "shoad stones," fragments of rocks and minerals known to be associated with and characteristic of the deposits. Fragments of coal, or soil stained black with coal, will be found near the outcrop of coal beds. Grains of gold or particles of ore may be detected by washing samples of gravel in a prospector's pan. By tracing such indications up the stream or up the hillside the outcrop may sometimes be found, or at least approximately located. The outcrop of a metalliferous vein frequently manifests itself as a line of rocks stained with oxide of iron, often honeycombed and porous, the "gossan" or "eisen-hut," the iron oxide of which results from the decomposition of the pyrites, usually present as a constituent of such veins. Other metals, such as manganese, copper, nickel, may show their presence by characteristic colours. Finally, the surface topography will often throw much light on the underground structure. The shape of the hills and ridges is necessarily influenced by the inclination of the strata, by the relative hardness of different rock-beds, and by the presence of folds and fissures and other lines of weakness. A quartz vein or bed of hard rock may show itself as a sharp ridge or as a well-defined bench; a stratum of soft rock or the line of a great fissure, or the weakening of the strata by an anticlinal fold, may produce a ravine or a deep valley. The bed of fire-clay under a coal seam, being impervious to water, frequently determines the horizon of numerous springs issuing from the hillsides. As the coal and the associated rocks usually contain pyrites, these springs are often chalybeate. When the location of the deposit has been determined approximately, further search is made by trenches or pits or borings through the surface soil.

Exploratory Work.—Before opening and working a mine it is necessary to have as full and accurate information as possible as to the following:—

1. The probable extent and area of the deposit, its average thickness, and the probable amount and value of the mineral;
2. The distribution of the workable areas of mineral in the deposit;
3. Conditions affecting the cost of opening, developing and working the mine or determining the methods to be adopted.

Work undertaken to secure this information must be distinguished from prospecting, which is the search for mineral deposits and from development, work undertaken to prepare for actual mining operations. Exploratory work is associated intimately both with prospecting and with development, but the purpose is quite distinct from either prospecting, development or working, and it is of importance that this should be clearly recognized. It must be remembered that the line between a workable deposit and one that cannot be profitably worked is often very narrow and that the majority of mineral deposits are not workable. The money that is spent in prospecting and in development is therefore liable to prove a loss. This is a recognized and legitimate business risk, differing only in degree from the risks attending all business operations. The risk of failure in mining enterprises is offset by the chances of more than ordinary profits. If the property proves valuable the returns may be very great. While the risk of loss of capital is not to be avoided, it is of the utmost importance to limit the amount of money expended while the extent and value of the deposit are still uncertain and to do the necessary work by the cheapest methods consistent with thoroughness. As the information as to the character and extent of the deposit becomes more definite, and as the prospects of success become more favourable, money may be spent more freely. The risk will vary with the character of the deposit. In the case of the cheaper and more abundant minerals, such as coal and iron ore, and of large deposits of low-grade ores, the extent and character of the deposit can generally be determined by surface examinations at comparatively small expense. On the other hand, in the case of less regular deposits, including most metalliferous veins, and especially those of the precious metals, the uncertainty is often very great, and it is sometimes necessary to work on a small scale for months before any considerable expenditure of money is justified.

The quickest and cheapest method is by surface explorations. The work of the prospector frequently furnishes much of the information required. By sinking additional pits or by extending the costeaning trenches and uncovering the outcrop of the deposit more fully it is sometimes possible to obtain all the

---

[1] Of doubtful origin. "Mine," both verb and substantive, come from the Fr., and is usually connected with Lat. *minare*, to drive or lead; but this would normally result in Fr. *mener*, not *miner*. Skeat, following Thurneysen, accepts a Celtic origin (cf. Irish *mein*, ore), but the *New Eng. Dict.* doubts this.

Surface Exploration.

information required for the most extensive and important mining operations. Even when the outcrop is oxidized, and the mineral character and richness of the deposit is altered thereby, it is possible to determine variations in thickness and the extent and distribution of the rich and barren areas by outcrop measurements. Information of this sort obtained by surface exploration is often as conclusive as similar information obtained from underground workings. If the deposit shows great variations in thickness in its outcrop along the surface it is probable that a drift or a slope would show the same thing in depth. If the workable areas are poor, and appear only at long intervals along the outcrop, the chances of discovering richer areas by a shaft are very small.

Boring.

In many cases underground exploration is necessary. For example, the deposit does not outcrop as in the case of blind veins and flat deposits below the general level of the country; or the outcrop lies beyond the limits of the property or under water or water-bearing formations, or is covered by quicksand, or is deeply buried. For such buried deposits boring is cheaper than sinking. In the case of coal, salt, iron ore, pyrite and other homogeneous minerals, boring may give all the information required. With a number of holes the average thickness and probable extent of the deposit may be determined, at least approximately. When the deposit is vertical or steeply inclined, horizontal or inclined bore-holes will be necessary. This will increase the cost of boring and will render the holes more likely to swerve from the true direction. In the case of metalliferous deposits of varying thickness or irregular distribution the information from bore-holes is less satisfactory. A large number of holes must be bored to obtain, even approximately, the average thickness and value of the ore and the shape and size of the ore bodies. In extreme cases the results from boring are likely to be untrustworthy and misleading unless the work is done on such a scale that the cost becomes prohibitory.

Underground Exploration.

While the information obtained by surface explorations is always valuable, and sometimes conclusive, as to the value of the deposit, it is usually necessary to supplement and confirm it by underground work. The outcrop of a metalliferous vein is generally more or less altered by oxidation, and often a part of the valuable mineral has been converted into a soluble form and leached out. These conditions sometimes extend to a considerable depth. Below the oxidized outcrop the vein is often increased in value by secondary enrichment, sometimes to a depth of several hundred feet. In the case of such altered deposits surface exploration alone is likely to be misleading, and it is important to push the underground exploration far enough to reach the unaltered part of the deposit, or at least deep enough to make it certain that there is a sufficient quantity of altered or enriched ore to form the basis of profitable mining operations. As the sinking of shafts or the driving of narrow entries or drifts is expensive, and as the mineral extracted rarely pays more than a small fraction of the cost, it is usual to plan this exploratory work so that the openings made shall serve some useful purpose later. The mistake is often made of sinking large and expensive shafts, or driving costly tunnels, before it is fully proved that the deposit can be worked on a scale to warrant such developments, and, indeed, too often before it is known that the deposit can be worked at all; and in too many cases large amounts of money are thus unnecessarily lost by over-sanguine mine managers. It is, however, often advisable that the money spent in surface or underground exploration should at the beginning be spent for information alone. The information so gained not only determines the value of the deposit, but also serves to indicate the best methods of development and of working. The money so spent, if judiciously used, insures the undertaking against loss by diminishing the mining risk, and is thus analogous to premiums paid to insure against fire or other sources of loss.

Development.—As soon as it appears reasonably certain that the property is workable the mine will be opened by one or more shafts, drifts or tunnels, and the underground passages for active mining operations will be started. A drift or entry is a horizontal passageway starting from the outcrop and following the deposit. The former term is used in metal-mines and the latter in coal-mining. A tunnel differs from a drift in that it is driven across the strata to intersect the deposit. Either may be used for drainage of the mine workings, in which case it becomes an adit. A mine should always be opened by drift or entry if practicable, as thereby the expense of hoisting and pumping is avoided. Drifts, entries and tunnels find their chief application in mining regions cut by deep valleys. When, however, the deposit lies below the surface the mine must be opened by a shaft. If the outcrop of the vein or bed is accessible the shaft may be inclined and sunk to follow the deposit. This is in general a cheaper and quicker method of development for inclined deposits than by a vertical shaft, and it has the added advantage that much information as to the character of the deposit is obtained as the shaft is sunk. When the deposit lying below the surface is horizontal, or nearly so, or when the outcrop of an inclined deposit is not accessible, a vertical shaft will be necessary. Vertical shafts are better adapted to rapid hoisting, and have therefore somewhat greater capacity, than inclined shafts. They are to be preferred also for very deep shafts, or for sinking in difficult ground. Drifts and inclined shafts following the deposit may prove difficult of maintenance when the workings become large and settlement of the overlying strata begins. Large pillars of mineral should be left for the protection of the main openings, whether these be shafts or adits. In the case of very thick beds and mass deposits the main shaft or tunnel will preferably be located in the foot-wall.

Figs. 1 and 2 illustrate the development of a metal-vein by two adits, two inclined shafts in the lode, and by a deep vertical shaft connected with the lode by horizontal cross cuts. The stippled areas represent the ore shoots and the white areas the barren portions of the lode. The levels are supposed to be 10 fathoms (60 ft.) apart. As the mine is opened the deposit is subdivided into blocks of convenient size by parallel passages, which form later the main haulage roads, and by transverse openings for ventilation. In metal-mines the main passages are known as levels, and these are connected at intervals by winzes or small shafts. In coal mines, entries and headings, bords and walls serve similar purposes. The size of the blocks or the distance between the main passages is determined mainly by considerations of convenience and economy in excavating and handling the

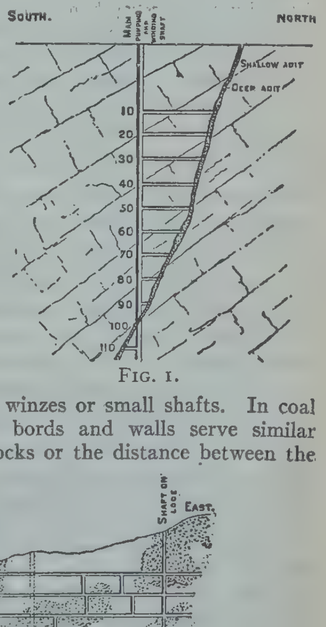


Fig. 1.

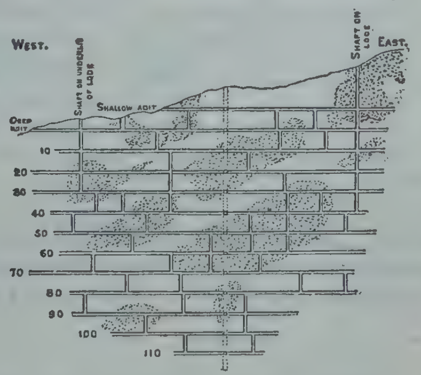

Fig. 2.

mineral, and by the possibility of supporting the roof long enough to permit the excavation of the mineral without unnecessary risk or expense. In metal mining, when the workable portions of the deposit are small and separated by unworkable areas, the levels serve also the purpose of exploration, and in such cases must not be so far apart as to risk missing valuable mineral. In coal-mines main entries are often 100 yds. apart, while in metal-mines the distance between levels rarely exceeds 50 yds. and sometimes is but 50 or 60 ft. In irregular and uncertain deposits this work of development should be kept at all times so far in advance of mining operations as to ensure a regular and uniform output. In some cases, where the barren areas are large, it may be necessary to have two or three years' supply of ore thus blocked out in advance. A mine, however, may be over-developed, which results in loss of interest on the capital unnecessarily locked up for years by excessive development, and involves additional cost for the maintenance of such openings until they are needed for active mining operations.

Working.—When the development of a mine has advanced sufficiently the operation of working or extracting the mineral begins. The method to be adopted will vary with the thickness and character of the deposit, with its inclination, and to some extent with the character of the enclosing rocks, the depth below the surface, and other conditions. The safety of the men must be one of the first considerations of the mine operator. In most civilized countries the safety of mine workers is guarded by stringent laws and enforced by the careful supervision of mine inspectors on behalf of the government. The method of mining adopted must secure the extraction of the mineral at a minimum cost. The principal item in mining cost is that of labour, which is expended chiefly in breaking down the mineral, either by the use of hand tools or with the aid of powder. Labour is also expended in handling the mineral in the working-places and in bringing it to the mine-cars in which it is brought to the surface. Narrow and contracted working-places are to be avoided, as in such places the cost of breaking ground is always large. Economy in handling makes it desirable to bring the mine-cars as near as may be to the point where the mineral is broken. This can be done in inclined deposits, it can often be done by the aid of mechanical appliances, though sometimes at an expense not warranted in the saving in the labour of loading. In steeply inclined beds the working-place can be so arranged that the mineral will fall or slide from the place where it is broken down to the main haulage road. The greatest difficulty is found where the inclination of the deposit is too great to permit the mine-cars to be brought into the working-place and yet not great enough to allow the mineral to fall or slide to a point where it can be loaded.

Size of Working-Places.

While it is always desirable to provide large working-places, the size of the working-place is limited by the thickness and strength of the overlying beds forming the roof or hanging wall of the mine. With thick and strong rocks the working-places may sometimes exceed 100 or even 200 ft. in width. Indeed in metal-mines 100 ft. is the usual distance from one level to the next. With weak and thin beds forming the roof the working-places are often not wider than 20 or 30 ft. as in most coal-mines. While the width of the working-place is thus limited by the strength of the roof, its length is determined by other considerations—namely, the rapidity with which the mining work can be conducted and the length of time it is practicable to keep the working-place open, and also by the increased difficulty of handling the minerals sometimes experienced when the workings reach undue length. In long-wall and in the work of mining pillars the roof will be supported on one side only, the overhanging beds acting as cantilevers. The working-place in such case is considerably narrower than in rooms or stopes, and there is also greater difficulty in supporting the roof because the projecting beds tend to break close to the point of support where the strain is greatest. This tendency is overcome by the use of timber supports so disposed as to ensure the breaking of the overhanging roof at a safe distance from the working-face and prevent the interruption of the work that might otherwise result.

Complete Extraction of Mineral.

While it is always desirable to work the deposit so as to extract the mineral completely, it frequently happens that this can only be done at greatly increased cost. In the case of cheap and abundant minerals and low-grade ore deposits it is sometimes necessary to sacrifice a considerable proportion of the mineral, which is left for the support of the overlying strata. A similar sacrifice in the shape of pillars is often necessary to support the surface, either to avoid injury to valuable structures or to prevent a flooding of the mine. As already noted large pillars must always be left to protect shafts, adits and the more important mine-passages necessary for drainage, ventilation and the haulage of mineral. In the early history of mining there was but little attempt at systematic development and working, and the mines were often irregular and tortuous. Fig. 3 is an old Mexican silver-mine of this type. In such mines the mineral was carried out on the backs of men, and the water was laboriously raised by a long line of suction-pumps, operated by hand, each lifting the water a few feet only. With but slight modifications permitting the use of pumps and hoisting-machinery equally simple methods of mining may be seen to-day when the deposit is of small extent.

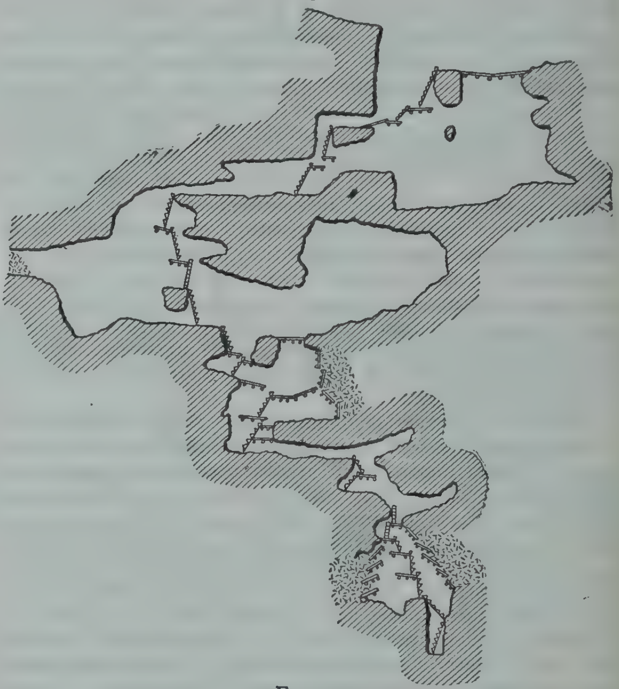

FIG. 3.

Fig. 4 is a portion of a mine which consists of a series of irregular chambers with the roof supported on small pillars left at intervals for the purpose. In the systematic mining of larger deposits, the simplest plan consists in mining large areas by means of numerous working-places under the protection of pillars of mineral left for the purpose, and later mining these pillars systematically, allowing the overlying rock beds to fall and fill the abandoned workings. In shallow mines the pillars are small and the saving of the mineral of minor importance. In deep mines the pillars may furnish the bulk of the product, and the control of the fall of the roof, so as to permit the successful extraction of the mineral, demands a well-schemed plan of operation. In the robbing of pillars, timber is necessary for the support of

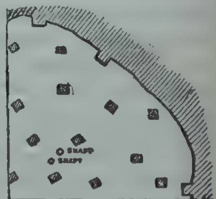

FIG. 4.

the roof in the working-places, and later to control the fall of the roof while the pillars are mined. More effective support and control of the roof may be secured by the use of rock-filling alone or with timber. By the use of rock-filling it is even possible to dispense with pillars of mineral; or, if pillars are left, the use of rock-filling greatly facilitates subsequent robbing operations. Rock-filling will be used whenever a large proportion of barren material must be mined with the ore. If rock-filling must be brought from the surface its use will generally be confined to mines in which it is difficult to support the roof in any other way. Rock-filling yields and becomes consolidated under heavy pressure, and therefore does not furnish a rigid support of the overlying strata, but rather a cushion to control and equalize the subsidence.

Room- and Pillar-Mining.

With soft material, pillars must be large, even at moderate depths below the surface, and it involves less labour to leave long rectangular pillars than to form numerous square ones. This leads to the adoption of the room and pillar system so common in coal-mining. Fig. 5 is a mine in a bed of soft iron ore worked by a series of inclined shafts, from which long horizontal rooms branch off right and left.

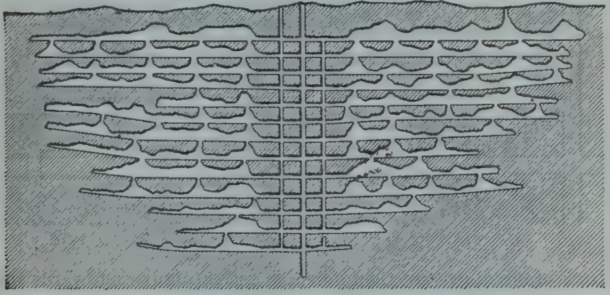

FIG. 5.

Stoping.

The usual method of working metal-mines is by overhand and underhand stoping, using rock-filling or pillars of mineral to support the roof. Fig. 6 represents a portion of one of the Lake Superior copper-mines worked by overhand stoping. A stope is that portion of the working assigned to a party of miners, and the block of ground is usually divided into three or four stopes at varying heights above the main level, the lowest being known as the cutting-out stope, the others as the first and second back stopes in ascending order. In steep pitching beds sufficient excavated material is allowed to remain in the stope for the support of the machines and men, the excess being drawn out from time to time and loaded into cars. The rest of the mineral is allowed to remain until the stope has so far advanced that its support is no longer needed. This method of mining requires but little timbering, only a single line of timber and lagging over the level, called the stull. When the roof is weak, or when it is undesirable to leave so much ore in the stopes, false stulls are sometimes erected in the upper part of the stope. The ore below the false stulls can then be drawn out without waiting for the completion of the top stope. When the mineral does not stand well in the pillar it will be necessary to erect a line of timbers with lagging so as to sheathe the under-side of the pillar and prevent its falling. It is not desirable to leave large areas standing upon pillars in the mine, and as soon as the work on any level is completed the pillar below should be mined out as far as is safe, and the abandoned portion of the mine allowed to cave in and lessen the weight on the pillars elsewhere. The block or ground between levels is sometimes mined by underhand stoping (fig. 7.). In this case the advanced drift is run underneath the pillar, and the ground below is mined in descending steps. This plan has the advantage of requiring little or no timbering when the mineral is strong enough to stand well in the pillars and when the hanging wall is good. The main haulage tracks are laid at the bottom of the stope, which thus forms the level. In this method of mining the different stopes must be kept close together; otherwise there is much added labour in shovelling the broken ore down to the main level. This method has the advantage of permitting the ore to be sent to the surface as fast as it is mined instead of being left for some months in the stopes for the men to stand upon. It has the disadvantage that the distance from one level to the next cannot usually be more than fifty feet without increasing greatly the chances of injury to the men from falling rock. The method is then practicable and safe only with exceptionally strong mineral and roof. In metal-mines producing abundant rock-filling the overhand method of stoping, illustrated in fig. 8, is used. In this the stoping contracts run vertically, and each party of contractors has one or more mills or timbered chutes through which the rich ore is conveyed to the level below and loaded in cars. The ore as mined is hand-picked and the barren material allowed to remain in the stope where it

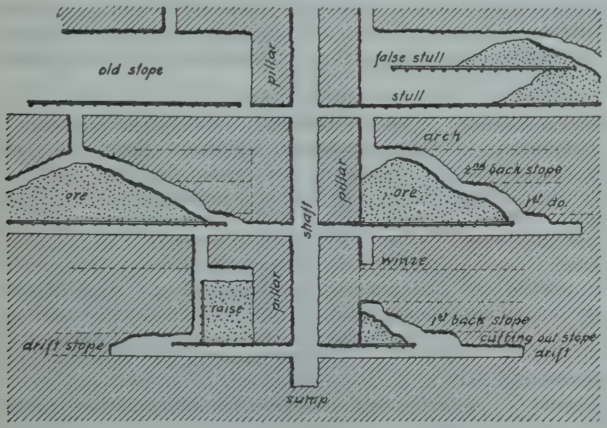

FIG. 6.

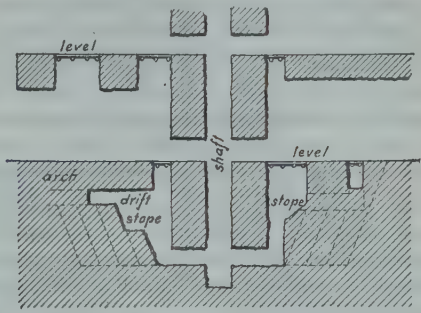

FIG. 7

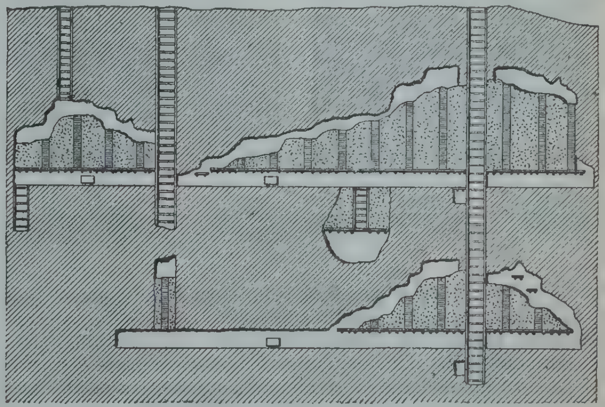

FIG. 8.

falls. In this method of mining no pillars need be left under the levels, as the rock-filling gives sufficient support to the roof. This method of mining affords the maximum of safety to the miners.

Working of Thick Deposits.

In the working of thick deposits the block of ground between two levels is divided into horizontal sections or floors which are worked either from above downward or from the bottom upward; in the first case the separate floors are worked by one of the caving systems; in the second, generally with the aid of filling. Fig. 9 illustrates the working of a block of ground by the top-slice caving system. Above, the ground has been completely worked out from the surface, and the space formerly occupied by ore is now filled with the débris of the overlying strata which has caved in above the block of ore now being worked. There is considerable thickness of old timber left from the working of the upper levels. This mat of timber forms a roof under the protection of which the mining of the ore proceeds downward floor by floor. The working-floors are connected by winzes with the main haulage roads below. These winzes serve for ventilation, for the passage of the workmen, and for chutes through which the ore is dumped to the level below. The working out of each floor is conducted much as if it were a bed of corresponding thickness. Haulage roads are driven in the ore so as to divide the floor into areas of convenient size. These separate areas are then mined in small rooms, each room being timbered as in mining under a weak roof rock. The room is driven in this way from one haulage road to another or to the boundary of the ore body. On completion of any room the timbers are withdrawn and the overlying mass of timber and rock is allowed to fall and a new room is started immediately alongside of the one just completed. In this way the whole floor is worked out and the mat of timber and overlying rock is gradually lowered and rests upon the top of the ore forming the floor below. Before abandoning a room it is usual to cover the bottom of the working-place with lagging-poles, which facilitate the mining of the floor below. In this manner one floor after another is worked until the floor containing the main haulage roads of the level below is reached. In the meantime a new level and a system of haulage roads have been driven a hundred feet below, and winzes have been driven upward to connect with the old level which is to be abandoned. The floor containing these old haulage roads now becomes the top slice of the one hundred-foot block of ground below and is mined out as described. Several floors may be mined simultaneously, the workings in the upper floor being kept in advance of those below, so as to allow the broken mass above to become consolidated before it is again disturbed by the working places of the next floor. This system permits the complete extraction of the ore at moderate cost and without danger to the men.

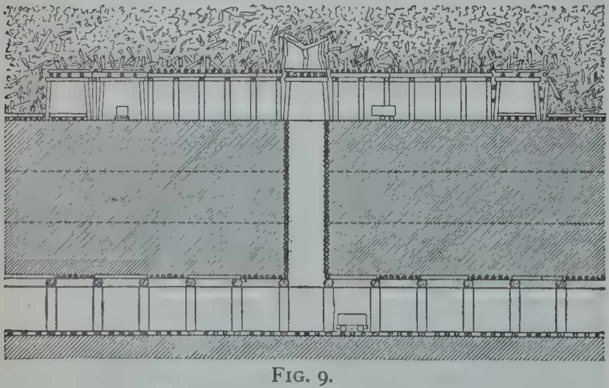

Fig. 9.

The subdrift caving system, fig. 10, differs from the top-slice system mainly in the greater thickness given to the working floors, which may be from 12 to 40 ft. in thickness, whereas in the top-slice system the height of the floor is limited by the length of the timbers used in the working-rooms, rarely over 8 or 10 ft. The subdrift system requires a smaller amount of narrow work in excavating the necessary haulage roads, and is therefore better adapted to hard ores in which such narrow work is expensive. The mining of each floor is carried on in sections with small working-places which are first driven of moderate height to their full length and width, leaving a back of ore above and pillars of ore between to support the upper portion of the upper layer or floor. These pillars and the back of ore above are then mined in retreating back towards the haulage road. The subdrift system is somewhat cheaper than the top-slice system, the output per man being greater.

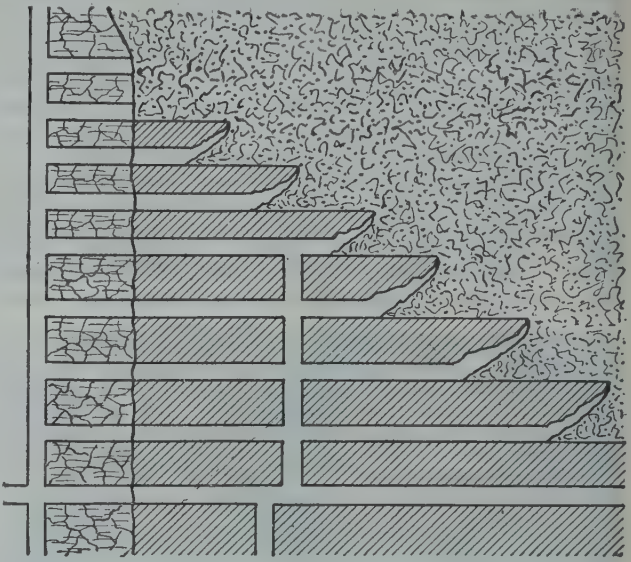

Fig. 10.

The bottom-slice caving system of mining begins at the bottom of a hundred-foot block of ground, a floor being excavated under the whole area, leaving pillars of sufficient size to support the ground above. These pillars are then filled with blast holes which are fired simultaneously, permitting the whole block of ground to the level above to drop. A floor is then reopened in this fallen ore, leaving pillars for temporary support which are blasted out as before. This is the cheapest of the three caving systems, but is applicable only when the deposit lies between walls of very solid rock, as otherwise wall rock is liable to cave with and become mixed with ore, which adds greatly to the expense of handling.

When rock filling is available, as when the ore contains much barren material to be left behind in mining, the ore body is divided into blocks of convenient height as above, and these blocks are divided into floors, the bottom floor of each block however being attacked. Each floor is opened up by subsidiary haulage roads and worked out in small rooms which are timbered and filled with broken rock when completed. An adjoining room is next excavated and filled, and thus the whole floor is worked out and replaced with rock-filling. Work is then started on the floor above, the upper floors being connected with the main haulage roads by winzes which are maintained through the filled ground. Several floors can be mined simultaneously, the work in the lower floors being kept well in advance. Instead of mining in horizontal floors the filling method permits the ore to be mined in vertical chambers or slices which extend from one level to the next above and from one wall of the deposit to the other. When a chamber has been excavated and completely filled the slice adjoining is mined out, or at times a block of ground may be left untouched between two filled chambers and then mined out. In the latter case the top-slice caving method will usually be employed for the working of such intervening pillars. In order to lessen the cost of handling the rock-filling, the excavation sometimes takes the form of inclined working-places, parallel to the slope naturally taken by the rock when dumped from above into the working place. This method of mining and filling can be used when the work is done in horizontal floors or in transverse chambers. In the United States the Nevada square set system of timbering is used in connexion with rock filling (fig. 11). The use of the heavy timbers and continuous framing which characterize this system facilitates greatly the work of mining and maintaining the haulage roads on the different floors, and gives more rigid support to the unmined portions of the block of ground above. These advantages compensate for the greater first cost. Where each floor is timbered by itself with light timbers, as is the practice on the continent of Europe, the consolidation of the rock-filling under pressure gives rise to considerable subsidence of the unmined ore, which has frequently settled 20 ft. or more before the upper part of the block is reached. This occasions much added expense in the maintenance and retimbering of the haulage roads on the upper floors. The shrinkage of the rock-filling and the settlement of the workings can be greatly lessened by the use of hard rock with a minimum of fine stuff; but even so the advantage lies with the American system of timbering.

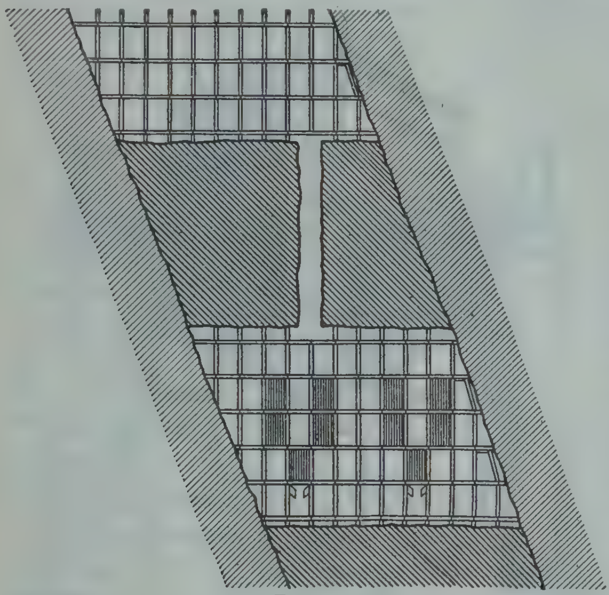

Fig. 11.

Sand Flushing.

The cost of filling has been greatly reduced by the system of flushing culm, sand, gravel and similar material, through pipes leading from the surface into mine workings. Material as coarse as 1 in. in diameter may be carried long distances underground with the use of little more than an equal volume of water. This method originated in the Pennsylvania anthracite mines in 1887, but has been employed in recent years on a large scale in Silesia, Westphalia and other European coalfields. In some cases it has been found advantageous to quarry and crush rock for the purpose of using it in this way. Examples of other mining methods will be found under Coal.

Open Workings.

Where mineral deposits lie near the surface underground mining may be replaced by open excavations, and the reduced cost of mining makes it possible to remove the overlying soil and rock to considerable depths. The depth to which open working can be pushed depends upon the size and value of the mineral deposit and upon the expense of removing the over-burden. Open excavations several hundred feet in depth are not uncommon. Where practicable steam shovels are employed, even when it is necessary to break up the material beforehand by blasting. Steam shovels are not well adapted to deep excavation unless provision is made for the rapid handling of the cars when filled. For deep workings the milling method is usually employed, in which the ore is excavated in funnel-shaped pits, each of which connects with underground haulage roads by a shaft. The ore is mined in the ordinary way, by pick and shovel if soft, or by the aid of powder if necessary, and the funnel-shaped bottom of the pit is maintained at such an angle that little or no shovelling is required to bring the excavated material to the shaft. Before the bottom of these pits reaches the level of the haulage roads below, a new set of roads will have been driven at a lower level and connected with the excavations above by the shafts. The cost of mining by the milling method does not greatly exceed the cost of steam-shovel work. For the special methods by which placer deposits are mined see Gold.

Underground Haulage.—The excavated material is brought to the hoisting shaft, or sometimes directly to the surface, in small mine cars, moved by men or by animals, or by locomotives or wire-rope haulage. The size, shape and design of the cars depend on the size of the mine passage and of the hoisting compartments of the shafts; on whether the cars are to be trammed by hand or hauled in trains; whether they are loaded by shovel or by gravity from a chute; and whether they are to be hoisted to the surface or used only for underground transport. The cost of underground haulage is lessened by the use of cars of large capacity. In the United States cars in the coal and iron mines hold from 2 to 4 tons. In Europe the capacity ranges from 1000 to 1500 ℔, though the tendency is to increase the size of the cars used. In mines of copper, lead and the precious metals, in which the cars are moved by hand, the usual load is from 1200 to 3000 ℔. These small cars are constructed so that the load may be dumped by pivoting the car bodies on the trucks. Larger cars are usually dumped by means of rotating or swinging cradles, the car bodies being rigidly attached to the axles or trucks. When loaded by shovel the car is made low to economize labour. Wooden rails, protected by iron straps, are sometimes used on underground roads for temporary traffic; but steel rails, similar to, though lighter than, those employed for railways are the rule. For hand tramming, animal and rope haulage, the rails weigh from 8 to 24 ℔ per yard, for locomotive haulage 30 to 40 ℔. Grades are made, whenever possible, in favour of the load, and of such degree that the power required to haul out the loaded cars shall be approximately equal to that for hauling back the empties, viz. about ½ of 1%. Sharp curves should be avoided, especially for mechanical haulage. Switches for turnouts and branches, &c., are similar to but simpler than those for railways.

Man and Animal Haulage.

In metal mines, where, as a rule, mechanical haulage is inapplicable, the cars are moved by men (trammers). This is expensive, but is made necessary by the small amount of material to be handled at any given point. The average speed is about 200 ft. per minute, and the distances preferably but a few hundred feet. Animal haulage is employed chiefly in collieries and large metal mines; sometimes for main haulage lines, but oftener for distributing empty cars and making up trains for mechanical haulage. In mines operated through shafts the animals are stabled underground, and when well fed and cared for, thrive notwithstanding their rather abnormal conditions of life. Mine cars are sometimes run long distances, singly or in trains, over roads which are given sufficient grade to impart considerable speed by gravity, say from 1 to 2½%. The grades must not be too great for brake control nor for the hauling back of the empty cars. Cars may thus be run through long adits or through branch gangways to some central point for making up into trains. Near the top and bottom of hoisting shafts the tracks are usually graded to permit the cars to be run to and from the shaft by gravity.

Locomotive haulage is applicable to large mines, where trains of cars are hauled long distances on flat or undulating roads of moderate gradients. Steam locomotives have been largely superseded by compressed air or electric locomotives. Compressed air locomotives are provided with cylindrical

Locomotive Haulage.

steel tanks charged from a special compressor with air at a pressure of 500 to 700 ℔ per sq. in. The capacity of the tank depends on the power required and the distance to be traversed by a single charge of air. The air passes through a reducing valve from the main to an auxiliary tank, in which the pressure is, say, 125 ℔, and thence to the driving cylinders. By using compressed air vitiation of the mine air is avoided, as well as all danger of fire or explosion of gas. Electric locomotives usually work on the trolley system, though a few storage battery locomotives have been successfully employed. Trolley haulage lacks the flexibility of steam or compressed air haulage, and is limited to main lines because the wires must be strung throughout the length of the line. By adopting modern non-sparking motors there is but little danger of igniting explosive gas. Electric and compressed air locomotives are durable, easily operated, and can be built to run under the low roofs of thin veins. Their power is proportioned to requirements of load and maximum gradient; the speed is rarely more than 6 or 8 m. per hour. Electric locomotives are in general more economical then either steam or compressed air.

Rope Haulage.

For heavy gradients rope haulage has no rival, though for moderate grades it is often advantageously replaced by electric and compressed air haulage. Gravity or self-acting planes are for lowering loaded cars, one or more at a time, from a higher to a lower level. The minimum grade is that which will enable the loaded cars in travelling down the plane to pull up the empty cars. At the head of the plane is mounted a drum or sheave, and around it passes a rope, one end of which is attached to the loaded cars at the top, the other to the empty cars at the foot. The speed due to the excess of weight on the loaded side is controlled by a brake on the drum. The rope is carried on rollers between the rails. There may be two complete lines of track or three lines of rails, one being common to both tracks, and the cars passing on a middle turnout or "parting"; or a single track with a parting. An engine plane is an inclined road, up which loaded cars are hauled by a stationary engine and rope, the empty cars running down by gravity, dragging the rope after them. This is similar to shaft hoisting, except that the grades are often quite flat. In the tail-rope system of haulage, best adapted for single track roads, there are two ropes—a main and a "tail" rope—winding on a pair of drums operated by an engine. The loaded train is coupled to the main rope, and to the rear end is attached the tail-rope, which reaches to the end of the line, passing there around a large grooved sheave and thence back to the engine. By winding in the main rope the loaded cars are hauled towards the engine, dragging behind them the tail-rope, which unwinds from its drum. The trip being completed, the empty train is hauled back by reversing the engine. The ropes are supported between the rails and guided on curves by rollers and sheaves. High speeds are often attained. Branches, operated from the main line, are readily installed. In the endless rope system the rope runs from a grip wheel on the driving engine to the end of the line, round a return sheave, and thence back to the engine. Chains are occasionally used. The line is double track and the rope constantly in motion, the cars being attached at intervals through its length by clips or clutches; the loaded cars move in one direction, the empties in the other. There are two modes of installing the system: either the rope passes above the cars and is carried by them, resting in the clips, or it is carried under the cars on rollers, the cars being attached by clips or a grip-carriage. (For details see Hughes, *Text-book of Coal Mining*, pp. 236–272; Hildenbrand, *Underground Haulage by Wire Rope*.) Rope haulage is widely used in collieries, and sometimes in other mines having large lateral extent and heavy traffic. With the tail-rope system, cars are run in long trains at high speed, curves and branches are easily worked, and gradients may be steep, though undulating gradients are somewhat disadvantageous. In the endless-rope systems cars run singly or in short trains, curves are disadvantageous, unless of long radius, speed is relatively slow, and branch roads not so easily operated as with tail-rope. The tail-rope plant is the more expensive, but for similar conditions the cost of working the two systems is nearly the same. An advantage of the endless system is that the cars may be delivered at regular intervals.

Winding Engine.

Hoisting.—When the mine is worked through shafts, hoisting plant must be installed for raising the ore and handling men and supplies. On a smaller scale hoisting is also necessary for sinking shafts and winzes and for various underground services. As ordinarily constructed, a pair of horizontal cylinders is coupled to a shaft on which are mounted either one or two drums (fig. 12). The diameter of the cylinders is such that each alone is capable of starting the load. As the cranks are set 90° apart, there is no dead centre, and the engine is able to start under full load from any point of the stroke. This is important in mine hoisting, which is intermittent in character and variable as to power and speed required. The cylinders are generally single-expansion, though compound engines are occasionally used for heavy work. The engine is direct-acting, the drums making one revolution for each double stroke. In geared hoists the drums are on a separate shaft, driven from the crank-shaft by tooth or friction gearing, and make one revolution for, say, 4 or 5 double strokes. The hoisting speed is therefore slower, and as less engine power is required for a given load the cylinders are smaller, though making more strokes per minute. Large and powerful geared hoists are not uncommon. The dimensions of the drum depend on the hoisting speed desired and the depth of shaft or length of rope to be wound. Drums are either cylindrical or conical. Conical drums (fig. 12) tend to equalize the varying load on the engine due to the winding and unwinding of the rope. On starting to hoist, the rope winds from the small towards the large end of the drum, the lever arm, or radius of the coils, increasing as the weight of

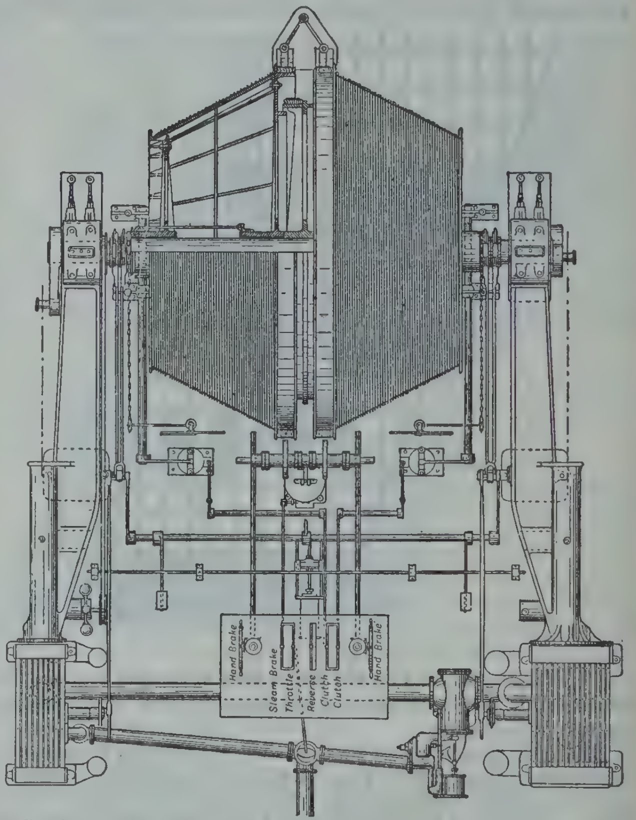

Fig. 12.—Plan of direct-acting hoisting engines, compound Corliss engines and conical drums. Wellman-Seaver-Morgan Co., Cleveland, Ohio, makers.

rope decreases. A similar equalizing effect is obtained by the use of flat rope and reel, the rope winding on itself like a ribbon. Tapering ropes, tail-ropes suspended from the cages, and other means of equalization, are also employed. If, for a two-compartment shaft, a pair of drums (or a single wide drum) be keyed to the engine shaft, with the ropes wound in opposite directions, the hoisting is "in balance," that is, the cages and cars counterbalance each other, so that the engine has to raise only the useful load of mineral, plus the rope. This arrangement allows no independence of movement: when the loaded cage is being hoisted the empty must be lowered. Independent drums, on the contrary, are loose upon their shaft, and are thrown on or off by tooth or friction clutches. The maximum load on the engine is thus greater and more power is required than for fixed drums. Steam consumption is economized, whenever possible, by throwing in the clutches of both drums and hoisting in balance. Fixed drums are best for mines in which the hoisting is done chiefly from one level; independent drums when there are a number of different levels. Hoisting engines are provided with powerful brakes and frequently with reversing gear. In deep shafts hoisting speeds of 3000 or 3500 ft. per minute are often attained, occasionally as much as 5000 ft.

Hoisting Ropes.

Formerly hemp and also fibre ropes were commonly used. Except in a few instances these were long ago superseded by iron-wire ropes, which in turn have been replaced by steel because of its greater strength. For hoisting in deep shafts, and to reduce the weight of rope, tempered-steel wire of very high tensile strength (up to 250,000 or 275,000 ℔ ultimate strength per sq. in.) is advantageously employed. A 1-in. ordinary steel rope has a breaking strength of about 32 tons, which, with a factor of safety of six gives a safe working load of 5¼ tons. A 1-in. plow-steel rope has breaking and working strengths respectively of at least 48 and 8 tons. Standard round rope (fig. 13) has six strands of 19 wires each and a hemp core. Flat rope is in favour in some districts. It is composed of several four-stranded ropes, without hemp centres, laid side by side, and sewed together by wire (fig. 14). It is not as durable as round rope and is heavier for the same working strength. As the sewing wires soon begin to break, a flat rope must usually be ripped apart and resewed every six or eight months. Numerous patent ropes, some having wires and strands of special shapes, have been introduced with the idea of improving the wearing properties. Such, for example, are the Lang-lay, locked-coil and flattened strand rope. Hoisting ropes are weakened by deterioration and breakage of the wires, due to corrosion and repeated bending, and should be kept under careful inspection. To prevent excessive bending stresses the diameter of drum and sheave must bear a proper ratio to that of the rope. A ratio of 48 to 1 is the minimum allowable; better 60 to 75 to 1, and for highly-tempered steel ropes ratios of 150 to 1 or more are desirable. To prevent corrosion the rope should be treated at intervals with hot lubricant. With proper care a steel rope should last from two to three years.

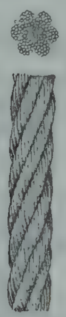

FIG. 13.—Standard round Rope.

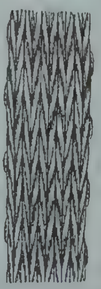

FIG. 14.—Flat Rope.

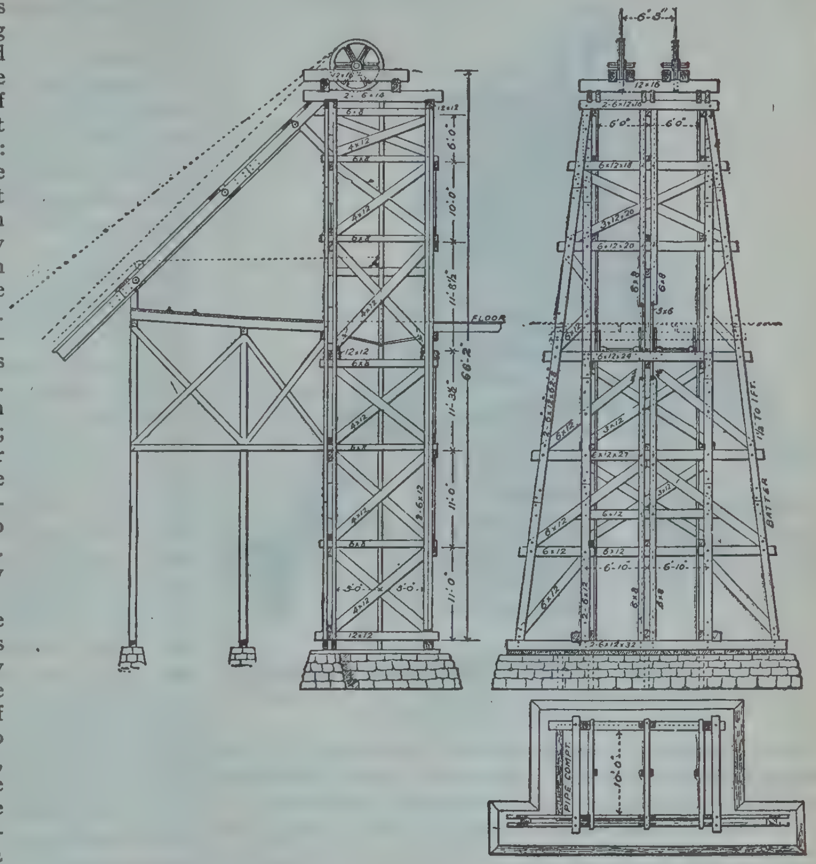
Head-gear.

A frame of wood or steel, erected at the shaft mouth, and carrying the grooved sheaves over which the hoisting ropes pass, is known as the head-gear (fig. 15). In Great Britain and her colonies it is also called the poppet-head or pit-head frame; in the United States head-frame or gallows-frame. Though it is small and simple in construction for light work, for heavy hoisting at high speeds massively framed towers, often 80 to 100 ft. in height, are built. Steel frames are more durable than those of wood, and have become common in nearly all mining countries, especially where timber is scarce. A German design is shown in fig. 16. The head-gear is often combined with ore-bins and machinery for breaking and sizing the lump ore previous to shipment to the reduction works.



(From *The Colliery Engineer*, May 1897.)

FIG. 15.—Head-gear.

Cages and Skips.

Cages, running in guides in the shaft, are used for raising the cars of mineral to the surface (fig. 17). They may have one, two or more decks, usually carrying one or two cars on each deck. Multiple-deck cages are rarely employed except for deep shafts of small cross-section or when the mine cars (tubs) are small, as in many parts of Europe. In many mines the mineral is raised in skips (fig. 18), filled from cars underground and dumping automatically on reaching the surface. Skips are sometimes of very large capacity, holding 5, 7, and even 10 tons of ore; such are used, for example, in several shafts at Butte, Montana, in the Lake Superior copper district, and in South Africa. Fig. 18 is a small skip; the upper illustration showing position for dumping. The lower cut is of a skip for either ore or water; note valve in bottom. Hoisting buckets or kibbles are employed for small scale work or temporary service, such as raising the material blasted in sinking shafts. They hold from a few hundred pounds up to 1 ton. In hoisting from great depths the weight of the rope, which may exceed that of the cage and contents, produces excessive variations in the load on the engine difficult to deal with. Moreover, the limit of vertical depth at which rope of even the best quality will support its own weight only, with a proper margin of safety, is, say, 10,000 to 12,000 ft.; and with the load the safe working limit of depth would be reached at 7000 to 8000 ft. A number of shafts in South Africa, the United States and elsewhere, are already approximating depths of 5000 ft., a few being even deeper. Ropes of tapering section may be used for great depths, but are not satisfactory in practice.[1] Stage hoisting is applicable to any depth. Instead of raising the load in one lift from the bottom of the shaft, one or more intermediate dumping and loading stations are provided. Each stage has its own engine, rope and cage. The variations in engine load are thus reduced, and incidentally hoisting time is saved.

Raising and Lowering Men. In shallow mines the men use the ladder-way in going to and from their work. This is sometimes the case also for considerable depths. It is more economical to save the men's strength, however, by raising and lowering them with the hoisting engines.

At mines with vertical shafts this is a simple operation. Cages of the size generally used in metal mines will hold from ten to fifteen and occasionally twenty men. The time consumed in lowering the men is shortened by the use of cages having two or more decks. These are common in Europe, and are sometimes employed in the United States and elsewhere in mines where the output is large and the shafts deep and of small cross section. While a shift of men is being lowered the miners of the preceding shift are usually raised to the surface in the ascending cages, the entire shift being thus changed in the time required for lowering. Nevertheless, in very deep and large mines the time consumed in handling the men may make serious inroads on the time available for hoisting ore. At a few mines special man-cages are operated in separate compartments by their own engines for handling part of the men, and for tools, supplies, &c. For inclined shafts, where the mineral is hoisted in skips, the operation of raising and lowering men may not be so simple. Even a large skip will hold but a few men, the speed is slower, and more time is required for the men to get into and out of the skip than to step on and off a cage. Moreover, skips are rarely provided with safety attachments, so that the danger is greater. When the shafts are deep and the number of miners large man-cars are sometimes employed. These are long frames on four wheels, with a series of seats like a section of a theatre gallery. Ordinarily 4 or 5 men occupy each seat, the car accommodating from 20 to 36 men. Such cars are in use at a number of deep inclined shafts in the Lake Superior copper district, where the depths range from 3000 to 5000 ft. or more. At a few mines (since safety catches cannot be successfully applied to man-cars) these conveyances are raised and lowered by separate engines and ropes. To replace the ore-skip expeditiously by the man-car when the shifts are to be changed a crane is often erected over the shaft mouth. At the end of a shift the ore-skip is lifted from the shaft track—the hoisting rope being uncoupled—and the man-car put in its place and attached to the rope. This change may be made in a few minutes.

Formerly, at many deep European mines, and at a few in the United States, men were raised by means of "man-engines."

Man-Engines. A man-engine consists of two heavy wooden rods (like the rods of a Cornish pumping plant), placed parallel and close to each other in a special shaft compartment, and suspended at the surface from a pair of massive walking beams (or "bobs"). The rods are caused to oscillate slowly by an engine, one rising while the other is falling. Thus they move simultaneously in opposite directions through a fixed length of stroke, say from 10 to 12 ft. At intervals on the rods are attached small horizontal platforms, only large enough to accommodate two men at a time. As the rods make their measured strokes one of the miners, starting from the surface, steps on the first platform as it rises to the surface landing and is then lowered on the down stroke. At the end of the stroke, when his platform comes opposite to a corresponding platform on the other rod, he steps over on to the latter during the instant of rest prior to the reversal of the stroke, descends with the second rod on this down stroke, steps again at the proper time to a platform of the first rod and so on to the bottom. The men follow each other, one by one, so that in a few minutes all the rod platforms in a deep shaft may be simultaneously occupied by men stepping in unison but in opposite directions from platforms of one rod to the other. Meantime, the men quitting work are ascending in a similar way, as there is room on each platform for two men at a time when passing each other. Man-engines were long used, but are now practically abandoned in both Great Britain and the United States, and few remain in any of the mining regions of the world. Their first cost is great and they are dangerous for new men, as they require constant alertness, presence of mind, and a certain knack in using them. See *Trans. Inst. Min. and Met.* xi. 334, 345, 380, &c.; also *Eng. and Min. Jour.* (April 4, 1903), pp. 517 and 518.

---

[1] A full discussion of this subject is given in *Trans. Ins. Min. and Met.*, vol. xi.

Surface Handling, Storage and Shipment of Minerals.—To mine ore or coal at minimum cost it is necessary to work the mine plant at nearly or quite its full capacity and to avoid interruption and delays. When the mineral is transported by rail or water to concentration or metallurgical works for treatment, or to near or distant markets for sale, provision must be made for the economical loading of railway wagons or vessels, and for the temporary storage of the mineral product. For short periods the mineral may remain in the mine cars, or may be loaded into railway wagons held at the mine for this purpose. Cars, however, are too valuable to be used in this way for more than a few hours, and it is usual to erect large storage bins at the mine, at concentration works and metallurgical establishments, in which the mineral may be stored, permitting cars, wagons and vessels to be quickly emptied or loaded. In mining regions where water transportation is interrupted during certain months of the year the mineral must be stored underground, or in great stock-piles on the surface. In coal mining the market demand varies in different seasons, and surface storage is sometimes necessary to permit regular work at the mines. For coal, iron ore and other cheap minerals, mechanical handling by many different methods is used in loading and unloading railway wagons and vessels, and in forming the stock-piles and reloading the mineral therefrom. (See CONVEYOR and DOCKS; also G. F. Zimmer, *Mechanical Handling of Materials*, and *Engineering Magazine*, xiv. 275, xx. 157 and xxi. 657.)

Mine Drainage.—A mine which has been opened by an adit tunnel or drift drains itself, so far as the workings above the adit level are concerned. In many mining regions long tunnels have been driven at great expense to secure natural drainage. Under modern mining conditions drainage tunnels have lost much of their former importance. Taking into account the risk attending all mining operations, which make necessary large interest and amortization charges on the cost of a tunnel, it will in most cases be advisable to raise the water to the surface by mechanical means. Drainage channels are provided, usually along the main haulage roads, by which the water flows to a sump excavated at the pump shaft. In driving mine passages that are to be used for drainage, care is taken to maintain sufficient gradient. Siphons are sometimes used to carry the water over an undulating grade and thereby save the expense of a deep rock cutting. As the larger part of the water in a mine comes from the surface, the cost of drainage may be reduced by intercepting this surface water, and collecting it at convenient points in the pump shaft from which it may be raised at less cost than if permitted to go to the bottom. Water may be raised from mines by buckets, tanks or pumps. Wooden or steel buckets, holding from 35 to 200 gallons, are employed only for temporary or auxiliary service or for small quantities of water in shallow shafts. Tanks operated by the main hoisting engines, and of capacities up to 1500 gallons or more, are applicable under several conditions: (1) When the shaft is deep, the quantity of water insufficient to keep a pump in regular operation, and the hoisting engine not constantly employed in raising mineral, the tank is worked at intervals, being attached temporarily to the hoisting rope in place of the cage. (2) For raising large volumes of water from deep shafts pairs of tanks are operated in balance in special shaft compartments by their own hoisting engine. With an efficient engine the cost per gallon of water is often less than for pumping. (3) For clearing flooded mines. As the water level falls the tanks readily follow it while at work, whereas pumps must be lowered to new positions to keep within suction distance. Self-acting tanks are occasionally built underneath the platforms of hoisting cages. Mine pumps are of two classes: (1) those in which the driving engine is on the surface and operates the pumps by a long line of rods passing down the shaft, commonly known as the Cornish system; (2) direct-acting pumps, in which the engine and pumping cylinders form a single unit, placed close to the point underground from which the water is to be raised. Cornish pumps are the oldest of the machines for draining mines; in fact, one of the earliest applications of the old Woolf and Newcomen engines in the 18th century was to pumps for deep mines. The engine works a massive counter-balanced walking-beam from which is suspended in the shaft a long wooden (or steel) rod, made in sections and spliced together. Attached to the rod by offsets are one or more plunger or bucket pumps, set at intervals in the shaft. All work simultaneously, each raising the water to a tank or sump above, whence it is taken by the next pump of the system, and finally discharged at the surface. The individual pumps are placed several hundred feet apart, so that a series is required for a deep shaft. The speed is slow—from 4 to 10 strokes per minute—but the larger sizes, up to 24 in. or more in diameter by 10 or 12 ft. stroke, are capable of raising millions of gallons per day. Cornish pumps are economical in running expenses, provided the driving engine is of proper design and the disadvantages incurred in conveying steam underground are avoided. Their first cost, however, is high and the cumbersome parts occupy much space in the shaft. Direct-acting pumps, first introduced (1841) by an American, Henry R. Worthington, are made of many different designs. Typically they are steam pumps, the steam and water cylinders being set tandem on the same bed frame, generally without fly-wheel or other rotary parts; they may be single cylinder or duplex, simple, compound or triple expansion, and having a higher speed of stroke are smaller in all their parts than Cornish pumps. For high heads the water cylinders, valves and valve chambers are specially constructed to withstand heavy pressures, water being sometimes raised in a single lift to heights of more than 2000 ft. Condensers are always required for underground pumps. Sinking pumps, designed for use in shafts in process of sinking, are suspended by wire ropes so as to be raised before blasting and promptly lowered again to resume pumping. Electrically driven pumps, now widely used, are convenient and economical. Mine pumps of ordinary forms may be operated by compressed air, and air-lift pumps have been successfully employed. Hydraulic pumping engines, while not differing essentially from steam pumps, must have specially designed valves in the power cylinder on account of the incompressibility of water. They can be used only when a supply of water under sufficient pressure is available for power. Centrifugal pumps, constructed with several stages or sets of vanes, and suitable for high lifts, have been introduced for mine service. When mine water is acid the working parts of the pump must be lined with or made of bronze or other non-corrosive material; or the acid may be neutralized by adding lime in the sump.

Ventilation.—The air of a mine is vitiated by the presence of large numbers of men and animals and of numerous lights, each of which may consume as much air as a number of men. In mining operations explosives are used on a large scale and the powder gases contain large quantities of the very poisonous gas, carbon monoxide, a small percentage of which may cause death, and even a minute percentage of which in the air will seriously affect the health. In addition to these sources of contamination the air of the mine is frequently charged with gas issuing from the rocks or from the mineral deposit. For example, carbon dioxide occurs in some mines, and hydrogen sulphide, which is a poisonous gas, in others. In coal-mines we have to deal with "fire-damp" or marsh gas, and with inflammable coal dust, which form explosive mixtures with air and frequently lead to disastrous explosions resulting in great loss of life. The gases produced by such fire-damp or dust explosions contain carbon dioxide and carbon monoxide in large proportion, and the majority of the deaths from such explosions are due to this "after-damp" rather than to the explosion itself. The terrible effects of fire-damp have led to the adoption of elaborate systems of ventilation, as the most effective safeguard against these explosions is the dilution and removal of the fire-damp as promptly and completely as possible. Very large volumes of air are necessary for this purpose, so that in such mines other sources of vitiation are adequately provided against and need not be considered. In metal mines, however, artificial ventilation is rarely attempted, and natural ventilation often fails to furnish a sufficient quantity of air. The examination of the air of metal mines has shown that in most cases it is much worse than the air of crowded theatres or other badly ventilated buildings. This has a serious effect on the health and efficiency of the workmen employed, and in extreme cases may even result in increased cost of mining operations. The ventilation of a mine must in general be produced artificially. In any case whether natural or artificial means be employed, a mine can only be ventilated properly when it has at least two distinct openings to the surface, one an intake or "downcast," the other a chimney serving as an "upcast." Two compartments of a shaft may be utilized for this purpose, but greater safety is ensured by two separate openings, as required by law in most mining countries.

Natural Ventilation.

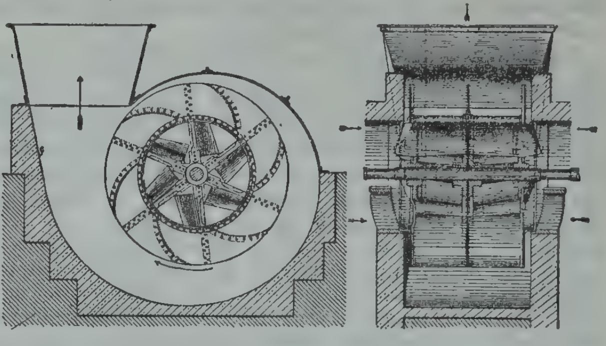
The air underground remains throughout the year at nearly the same temperature, and is warmer in winter and cooler in summer than the outside air. If the two openings to the mine are at different levels the difference in weight of the inside and outside air due to difference in temperature causes a current, and in the winter months large volumes of air will be circulated through the mine from this cause alone. In summer there will be less movement of air and the current will frequently be reversed. In a mine with shafts opening at the same level, natural ventilation once established will be effective during cold weather, as the downcast will have the temperature of the outside air, while the upcast will be filled with the warm air of the mine. In summer this will occur only on cool days and at night. When the temperature of outside and inside air becomes equal or nearly so natural ventilation ceases or becomes insignificant. In a mine with two shafts a ventilating current may result from other conditions creating a difference in the temperature of the air in either shaft—for example, the cooling effect of dropping water or the heating effect of steam pipes. Natural ventilation is impracticable in flat deposits worked by drifts and without shafts.

Ventilating Furnaces.

Ventilation may be produced by heating the air of the mine, as for example, by constructing a ventilating furnace at the bottom of an air shaft. The efficiency of such ventilating furnaces is low, and they cannot safely be used in mines producing fire-damp. They are sometimes the cause of underground fires, and they are always a source of danger when by any chance the ventilating current becomes reversed, in which case the products of combustion, containing large quantities of carbon dioxide, will be drawn into the mine to the serious danger of the men. On account of their dangerous character furnaces are prohibited by law in many countries.

Mechanical Ventilators.

Positive blowers and exhausting apparatus of a great variety of forms have been used in mines for producing artificial ventilation. About 1850, efficient ventilators of the centrifugal type were first introduced, and are now almost universally employed where the circulation of large volumes of air is necessary, as in collieries. The typical mine fan consists of a shaft upon which are mounted a number of vanes enclosed in a casing; the air entering a central side inlet is caught up by the revolving vanes and thrown out at the periphery by the centrifugal force thus generated. "Open-running" fans have no peripheral casing, and discharge freely throughout their entire circumference; in "closed" fans the revolving part is completely enveloped by a spiral casing opening at one point into a discharge chimney. Fans either force air into or exhaust it from the mine. The inlet opening of the pressure fan is in free communication with the outside air, the discharge connecting with the mine air-way; in the more generally used exhaust fan the inlet is connected with the air-way, the fan discharging into the atmosphere. Among the exhaust fans most widely employed is the Guibal. Many others have been introduced, such as the Capell (fig. 19), Rateau, Schiele, Pelzer, Hanarte, Ser, Winter, Kley, and Sirocco fans. The Waddle may be instanced as an example of the open fans. Slow-speed fans are sometimes of large dimensions, up to 30 and even 45 ft. diameter, discharging hundreds of thousands of cubic feet of air per minute. Occasionally, at very gassy and dangerous collieries, two fans and driving engines are erected at the same air shaft, and in case of accident to the fan in operation the other can be started within a few minutes.



(From *Mines and Minerals*, March, 1905.)

Fig. 19.—Capell Fan.

Circulation of Air.

Opposed to the motive force producing the air current is the frictional resistance developed in passing through the mine workings. This resistance is equal to the square of the velocity of the current in feet per minute, multiplied by the total rubbing or friction surface of the air-ways in square feet and by the coefficient of friction. The latter, determined experimentally, varies with different kinds of surfaces of mine workings, whether rough or smooth, timbered or unlined; it ranges from 0·000000001872 to 0·0000000217 lb per sq. ft., the latter being the value usually adopted. A certain pressure of air is required to maintain circulation against the resistance, and for a given volume per minute the smaller and more irregular the mine openings the greater must be the pressure. The pressure is measured by a "water-gauge" and the velocity of flow by an "anemometer." The power required to circulate the air through a mine increases as the cube of the velocity of the air current. To decrease the velocity, when large volumes of air are required, the air passages are made larger, and the mine is divided into sections and the air current subdivided into a corresponding number of independent circuits. This splitting of the air not only lessens the cost of ventilating, but greatly increases its efficiency by permitting the circulation of much larger volumes, and has the added advantage that the effect of an explosion or other accident vitiating the air current is often confined to a single division of the mine, and affects but a small part of the working force. The adjustment of the air currents in the different splits is affected by regulators which are placed in the return air-ways, and act as throttle valves to determine the volume of air in each case. The circulation of air in any given division of the mine is further controlled and its course determined by temporary or permanent partitions ("brattices"), by the erection of stoppings, or by the insertion of doors in the mine passages and by the use of special air-ways (see Coal). In devising a system of ventilation it is customary to subdivide the workings so that the resistance to the ventilating current in each split shall be nearly equal, or so that the desired amount of air shall be circulated in each without undue use of regulating appliances which add to the friction and increase the cost of removing the air. In addition to this it is desirable to take advantage of the natural ventilation, that is, to circulate the air in the direction that it goes naturally, as otherwise the resistance to the movement of the air may be greatly increased. So far as possible, vitiated air is led directly to the shaft instead of passing through other workings; for example, mine stables when used are placed near the upcast shaft and ventilated by an independent split of the ventilating current.

Deep Mining.—There has been much speculation as to the depth to which it will be practicable to push the work of mining. The special difficulties which attend deep mining, in addition to the problems of hoisting ore and raising water from great depths, are the increase of temperature of the rocks and the pressure of the overlying strata. The deepest mine in the world is No. 3 shaft of the Tamarack mine in Houghton county, Michigan, which has reached a vertical depth of about 5200 ft. Three other shafts of the Tamarack Company, and three of the neighbouring Calumet and Hecla mine, have depths of between 4000 and 5000 ft. vertical. The Quincy mine, also in Houghton county, has reached a vertical depth of nearly 4000 ft. In England are several collieries over 3000 ft., and in Belgium two are nearly 4000 ft. deep. In Austria three shafts in the silver mines at Prizbram have reached the depth of over 1000 metres. At Bendigo in Australia are several shafts between 3000 and 4000, and one, the Victoria Quartz mine, 4300 ft. deep. In the Transvaal gold region (South Africa), a number of shafts have been sunk to strike the reef at about 4000 ft. In most cases the deposits worked are known to extend to much greater depths than have been reached. The possibility of hoisting and pumping from great depths has been discussed, and it remains now to consider the other conditions which will tend to limit mining operations in depth—namely, increase of temperature and increase of rock pressure. Observations in different parts of the world have shown that the increase of temperature in depth varies: in most localities the rise being at the rate of one degree for 50 to 100 feet of depth; while in the deep mines of Michigan and the Rand, an increase as low as one degree for each 200 ft. or more has been observed. In the Comstock mines at Virginia City, Nevada, it is possible to continue mining operations at rock temperatures of 130° F. In these mines a constant supply of pure air, about 1900 cub. ft. per minute, was blown into the hot working places through light iron pipes. The air issuing from these pipes was dry and warm, and served to keep the temperature of the air below 120°, at which temperature it was possible for men to work continuously for half an hour at a time, and for four hours in the day. In some places work was conducted with rock temperatures as high as 158° F., with air 135° F. In these very hot drifts the fatality was large. In the Alpine tunnels, where the air was moist and probably not as pure as in the Comstock mines, great difficulty was experienced in prosecuting the work at temperatures of 90° F. and less. The mortality was large, and it was believed by the engineers that temperatures over 104° would have proved fatal to most of the workmen. Deep mines, however, are generally dry, so that in most cases it will be possible to realize the more favourable conditions of the Comstock mines. Assuming an initial mean temperature of 50° F., and increments of one degree for 100 and for 200 ft., a rock temperature of 130° will be reached at 8000 to 16,000 ft. In many deep mines to-day "explosive rock" has been encountered. This condition manifests itself, for example, in mine pillars which are subjected to a weight beyond the limit of elasticity of the mineral of which they are composed. Under such conditions the pillar begins to yield, and fragments of mineral fly off with explosive violence, exactly as a specimen of rock will splinter under pressure in a testing machine. The flying fragments of rock have frequently injured and sometimes killed miners. A similar condition of strain has been observed in deep mines in different parts of the world—perhaps due to geological movements. Assuming a weight of 13 cub. ft. to the ton, then at 6500 ft. the pressure per sq. ft. will be 500 tons, and at 13,000 ft. 1000 tons; and as the mineral is mined the weight on the pillars left will be proportionately greater. At such pressures all but the strongest rocks will be strained beyond their limit of elasticity. At depths of 1000 ft. and less some of the softer rocks show a tendency to flow, as exhibited by the under-clay in deep coal-mines, which not infrequently swells up and closes the mine passages. In the Mont Cenis tunnel a bed of soft granite was encountered that continued to swell with almost irresistible force for some months. The pressure developed was sufficient to crush an arched lining of two-foot granite blocks. Similar swelling ground is not infrequently met with in metal mines, as, for example, in the Phoenix copper mine in Houghton county, Michigan, where the force developed was sufficient to crush the strongest timber that could be used. In very deep mines this flowing of soft rock will doubtless add greatly to the difficulty of maintaining openings. What may happen in some cases is illustrated by the curious form of accident locally known as a "bump," which occurs in some of the deep coal-mines of England. In one instance (described by F. G. Meacham, *Trans. Fed. Inst. M.E.* v. 381), the force developed by the swelling under-clay broke through and lifted with the force and suddenness of an explosion a lower bench of coal 8 ft. thick in the bottom of a gangway 12 ft. wide for a length of 200 ft., throwing men and mine cars violently against the roof and producing an air-wave which smashed the mine doors in the vicinity. It is apparent that the combined effect of internal heat and rock pressure will greatly increase the cost of mining at depths of 8000 or 10,000 ft., and will probably render mining impracticable in many instances at depths not much greater.

Mine Administration.—In organizing a mining company it must be recognized that mining is of necessity a temporary business. When the deposit is exhausted the company must be wound up or its operations transferred to some other locality. Mining is also subject to the risks of ordinary business enterprises, and to additional risks and uncertainties peculiar to itself. The vast majority of mineral deposits are unworkable, and of those that are developed a large proportion prove unprofitable. In addition mining operations are subject to interruption and added expense from explosions, mine fires, flooding, and the caving-in of the workings. To provide for the repayment from earnings of the capital invested in a mining property and expended in development, and to provide for the depreciation in value of the plant and equipment, an amortization fund must be accumulated during the life of the mine; or, if it be desired to continue the business of mining elsewhere, a similar fund must be created for the purchase, development and equipment of a new property to take the place of the original deposit when that shall be exhausted. If, for example, we assume the life of a given mine at ten years and the rate of interest at 5%, it will be necessary that the property shall earn nearly 13% annually—viz., 5% interest and 8% for the annual payment to the amortization or the reserve fund. To cover the special risks of mining, capital should earn a higher interest than in ordinary business, and if we assume that the sinking-fund be safely invested, we must compute the amortization on a lower basis than 5%. Assuming, for example, the life of the mine at ten years as before, and taking the interest to be earned by the amortization fund at 3%, and that on the investment at 10%, we shall find that the annual income should amount to 18·7% per year. These simple business principles do not seem to be generally recognized by the investing public, and mines, whose earning capacity is accurately known, are frequently quoted on the stock markets at prices which cannot possibly yield enough to the purchaser to repay his investment during the probable life of the mine.

Mine Valuation.—The value of any property is measured by its annual profits. In the case of mining properties these profits are more or less uncertain, and cannot be accurately determined until the deposit has been thoroughly explored and fully developed. In many instances, indeed, profits are more or less uncertain during the whole life of the mine, and it is evident that the value of the mining property must be more or less speculative. In the case of a developed mine its life may be predicted in many cases with absolute certainty—as when the extent of the mineral deposit and the volume of mineral can be measured. In other cases the life of the mine, like the value of the mineral, is more or less uncertain. Further, both time and money are required for the development of the mining property before any profit can be realized. Mathematically we have thus in all cases to compute present value on the basis of a deferred as well as a limited annuity. The valuation of mines then involves the following steps: (1) The sampling of the deposit so far as developed, and assaying of the samples taken; (2) The measurement of the developed ore; (3) estimates of the probable amount of ore in the undeveloped part of the property; (4) estimates of probable profits, life of the mine, and determination of the value of the property. Where the deposit is a regular one and the mineral is of fairly uniform richness, the taking of a few samples from widely separated parts of the mine will often furnish sufficient data to determine the value of the deposit. On the other hand in the case of uncertain and irregular deposits, the value of which varies between very wide limits, as, for example—in most metal mines and especially mines of gold and silver—a very large number of samples must be taken—sometimes not more than two or three feet apart—in order that the average value of the ore may be known within reasonable limits of error. The sampling of a large mine of this character may cost many hundreds of pounds. This applies with even greater force to estimates of undeveloped portions of the property. If the deposit is regular and uniform, the value of undeveloped areas may sometimes be predicted with confidence. In the majority of instances, however, the estimates of undeveloped ore contain a large element of uncertainty. In order to determine the probable profit and life of the mine a definite scale of operations must be assumed, the money required for development and plant and for working capital must be estimated, the methods of mining and treating the ore determined, and their probable cost estimated. Where the deposit is uncertain and the element of risk is large, we must adopt a high rate of interest on investments of capital in our computations of value—in some cases as high as 10, 15 or even 20%. Where the deposit is regular and the future can be predicted with some degree of certainty, we may be justified in adopting in some cases possibly as low as 5%. The interest on the annual contribution to the sinking-fund or its equivalent should be reckoned at a low rate of interest, for such funds are assumed to be invested in perfectly safe securities. Allowance must be made for the period of development during which there are no contributions to the sinking-fund and within which no interest is earned on invested capital.

Mining Education.—It is necessary to have the work directed by men thoroughly familiar with the characteristics of mineral deposits, and with wide experience in mining. For the purpose of training such men special schools of mining engineering (*écoles des mines*, *Bergakademie*) have been established in most mining countries. A student of mining must receive thorough instruction in geology; he must study mining as practised in different countries, and the metallurgical and mechanical treatment of minerals; and he should have an engineering education, especially on mechanical and electrical lines. As he is called upon to construct lines of transport, both underground and on the surface, works for water-supply and drainage, and buildings for the handling, storage and treatment of ore, he must be trained to some extent as a civil engineer. As a foundation his education must be thorough in the natural and physical sciences and mathematics. In addition there have been established in many countries schools for the education of workmen, in order to fit them for minor positions and to enable them to work intelligently with the engineers. These miners' schools (*Bergschule*, *écoles des mineurs*) give elementary instruction in chemistry, physics, mechanics, mineralogy, geology and mathematics and drawing, as well as in such details of the art of mining as will best supplement the practical information already acquired in underground work. The training of a mining engineer merely begins in the schools, and mining graduates should serve an apprenticeship before they accept responsibility for important mining operations. It is especially necessary that they should gain experience in management of men, and in the conduct of the business details, which cannot well be taught in schools.

Accidents.—Mining is an extra-hazardous occupation, and the catastrophes, which from time to time have occurred, have caused the enactment of laws to protect the lives of the men engaged in underground work. These laws are enforced by mine inspectors who are empowered to call upon the courts and other government agencies to enforce their authority. While in some cases these laws are unnecessarily stringent and tend to restrict the business of mining yet on the whole they have had the effect of reducing greatly the loss of life and injuries of miners where they have been well enforced. This is evident from fig. 20, which shows the number of men killed in the coal and metal mines of Great Britain for a series of years. As will be seen from this diagram the most serious source of death and injury is not found in mine explosions, but in the fall of rocks and mineral in the working places. This danger can be reached only in small degree by laws and inspection; but the safety of the men must depend upon the skill and care of the miners themselves and the officers in charge of the underground work. Great loss of life and injury occur through the ignorance, carelessness and recklessness of the men themselves, who fail to take the necessary precautions for their own safety, even when warned to do so. Mining laws have proved chiefly serviceable in securing the introduction of efficient ventilation, the use of safety-lamps, and of proper explosives, to lessen the danger from fire-damp and coal-dust in the coal-mines, the inspection of machinery for hoisting and haulage, and prevention of accidents due to imperfection in design or in working the machinery.

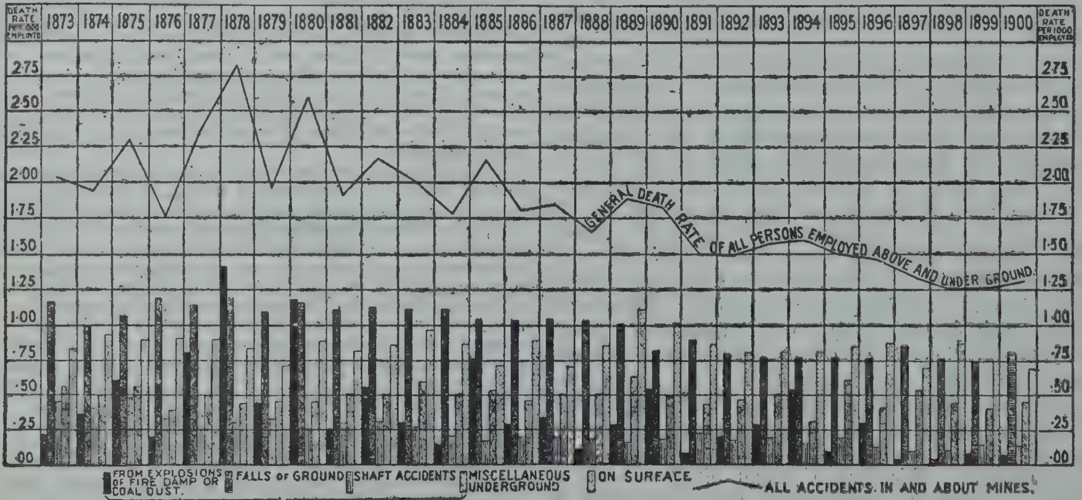


FIG. 20.—Death-rate from various classes of accidents in and about all mines in the United Kingdom from 1873 to 1900.

Explosions. Fire-damp and dust explosions are caused by the presence of marsh-gas in sufficient quantity to form an explosive mixture, or by a mixture of small percentages of marsh-gas and coal-dust, and in some cases by the presence of coal-dust alone in the air of the mine. Explosive mixtures of marsh-gas and air may be fired by an unprotected light. But when coal-dust is present, and little or no marsh-gas, an initial explosion—such as is produced by a blown-out shot—is required. To guard against explosions from this cause it is necessary to use explosives in moderate quantities and to see that the blast-holes are properly placed, so that the danger of blown-out shots may be lessened. In dry and dusty mines the danger may be greatly lessened by sprinkling the working places and passages, and the removal of the accumulated dust and fine coal. Where large quantities of fire-damp are present, safety-lamps of approved pattern must be used and carefully inspected daily. The use of matches and naked lights of any kind must be prohibited. To lessen the danger from blasting operations the use of special safety explosives is required in Great Britain and some European countries. The use of such explosives decreases to some extent the danger from dust explosions; but experiment shows that no efficient explosive is absolutely safe, if used in excessive quantity, or in an improper manner. Absolute security is impossible, as is proved by the many and serious disasters under the most stringent laws and careful regulations that can be devised.

Mine Fires. Mine fires may originate from ordinary causes, but in addition they may result from the explosion of fire-damp or from the accidental lighting of jets of fire-damp issuing from the coal. In some mining districts the coal is liable to spontaneous combustion. A fire underground speedily becomes formidable, not only in coal but also in metal mines, on account of the large quantity of timber used to support the excavations. Underground fires may sometimes be extinguished by direct attack with water. The difficulty of extinguishing an underground fire in this way is, however, very great, as on account of the poisonous products of combustion it is impossible to attack it except in the rear, and even there the men are always in great danger from the reversal of the air current, or back-draught from the fire. Further, the burning of the timber produces falls of ground, making necessary the excavation and removal at times of hundreds of tons of heated rock and burning coal, in order to reach the fire. When direct attack is no longer practicable, it is possible to extinguish the fire by sealing the mine workings, and exhausting the supply of oxygen. It is necessary, however, to keep the mine sealed until the burning timbers, or coal, and the red-hot rocks have become cool, or the fire will again break out. This sometimes requires two or three months. Where an effective sealing of the mine is impracticable it is sometimes possible to extinguish the fire from the outside of the mine by constructing a large reservoir or tank in the upper part of the mine-shaft and suddenly releasing a large volume of water by opening discharge-doors. The mass of water falling down the shaft is converted into spray, which is carried by the force of the fall long distances into the workings. Where the fire is in or near the shaft this method has proved very effective. Mine fires may sometimes be reached by bore-holes sunk for the purpose from the surface, and the burning workings below filled by flushing with culm and water. As a last resort the mine may be flooded with water. This is an expensive operation as it entails the cost of pumping the water out again and repairing the resulting damage. If the fire is in working places to the rise the water may not reach the burning portions of the mine, but will effectually seal them. But sufficient time must be allowed to elapse before pumping out the water, as otherwise the fire may break out again.

Flooding of Mines.

Mines may become flooded by the inrush of surface waters in times of great rainfall or sudden floods, or by the undermining of surface waters. The mine workings may also be flooded by large bodies of underground water. The surface floods must be provided with channels of sufficient size to carry them safely past the mine openings, and intercepting ditches should be excavated for this purpose, and dams and embankments constructed to divert the flood waters. That it is possible to work with safety beneath rivers, lakes and even the ocean has been proved in numerous instances; mines in different parts of the world having been extended long distances under the sea. In such cases preliminary surveys should be made to determine the thickness of rock over the proposed workings. Under favourable conditions mining may be conducted under the protection of a few yards of solid rock only, as in the submarine work for the removal of reefs in the harbours of San Francisco and New York. At Silver Islet, Lake Superior, mining was successfully carried on for years under the protection of a coffer dam and an arch of rich silver ore less than 20 ft. thick. At Wheal Cock near St Just in Cornwall the protecting roof was so thin that holes bored for blasting more than once penetrated to the bed of the ocean, and wooden plugs were kept on hand to drive into such holes when this occurred. In storms the boulders could be heard striking each other overhead. When large areas are undermined, as in submarine coal mining, it is best to have several hundred feet of protecting rock. In Great Britain the law requires that the workings shall be protected by 120 ft. of solid strata. When the presence of underground bodies of water is known or suspected, advance bore-holes should radiate from the end of the advancing working place so as to give warning of the position of the body of water, these holes being of such length as to ensure a safe thickness of solid rock.

Caving of Mine Workings.

The caving in of mine workings results from the excavation of large areas supported upon pillars of insufficient size. While the mine workings are small the overlying rocks support themselves and the full pressure does not come upon the mine pillars. As the workings increase in size the pillars support an increasing weight until finally they are strained beyond the limit of elasticity. When this occurs, the pillars begin to crack and splinter with a noise like musketry firing, and the roof of the mine shows signs of subsidence. This may continue for weeks before the final crash takes place. At first a fall of the roof occurs locally, here and there throughout the mine, and these falls may succeed one another until the settlement of portions of the roof has so far relieved the strain that the remaining areas are supported by the stronger pillars, and by the fallen rock masses. While abundant warning of the caving-in of the workings is thus given in advance it may happen that men are unexpectedly imprisoned by the closing of the main passage ways. The caving-in of the mine, however, is rarely so complete that avenues of escape are not open. In many cases, however, it has been found necessary to reopen the mine through the fallen ground, and even to excavate openings through the solid mineral. The history of mining is full of dramatic episodes of this character.

Accidents from Explosives.

Accidents from the misuse and careless handling of explosives are unfortunately too frequent in mines. The conditions under which explosives may be stored, handled and used are carefully formulated in the mining laws of most states, but it is almost impossible to secure obedience to these regulations on the part of the miners, who are, as a rule, both careless and reckless in their use of powder. In some states it has become necessary to provide for fines and even imprisonment of men disobeying the regulations regarding explosives.

Mine Hygiene.—While mining is not necessarily an unhealthy occupation, miners are subject to certain diseases resulting from vitiated air, and from unusual or special conditions under which at times they are forced to work. Recent investigations have shown an alarming increase in mortality from miners' phthisis in Cornwall, South Africa and elsewhere. This seems to be due to the dust abundantly produced in mining operations, and especially by machine drills when boring "dry" (rising) blast holes. Drill runners, who are compelled to breathe this dusty air daily, furnish most of the sufferers from phthisis. The increased mortality seems to be due to the general tendency toward forced speed in development work, which is secured by rapid drilling, and by an increase in the number of machine drills used in a single working-place. The miners, to save time, often return to their work after blasting before the powder-smoke and dust have been sufficiently removed. It is probable that the carbon monoxide seriously affects the general health and vitality of the men, and renders them more likely to succumb to phthisis. More effective ventilation will materially lessen the death-rate. In the metal mines of Cornwall and Devon special rules are now in force requiring the use of water in drilling, and other precautions, to lessen this danger from dust. In some mines dust seems to have but little effect on the health of the miners; indeed it is even claimed by some that coal dust decreases the mortality from phthisis. On the other hand, as in mining ores containing lead, arsenic and mercury, the dust may be poisonous. The climbing of ladders from deep mines not only lessens the efficiency of the men by reason of fatigue, but often tends to increase the mortality from diseases of the heart. In cold climates men coming from the warm atmosphere of a mine, often in wet clothing, are liable to suffer in health unless proper provision is made for the necessary change of clothing. In such cases the establishment of dressing-rooms, properly heated, and connected with the mine by covered passages will be necessary. These "change-houses" are provided with washing and bathing facilities, and arrangements for drying wet clothing. Ankylostomiasis (*q.v.*) is a disease which finds a congenial habitat in the warm damp atmosphere of mines, and has become a veritable scourge in some mining regions. The disease yields readily to treatment, but is difficult to eradicate from a mine without stringent sanitary regulations to prevent its spread. The care of the health of the working force should be entrusted to competent mine physicians, thoroughly familiar with the conditions under which the miners work, and with the special diseases to which they are subject. The men should be instructed in the laws of sanitation, and in the proper care of injured men.

Mine Law.—Mine law is that branch of the law of real property relating to mineral and mining rights as distinct from rights pertaining to the surface of the ground. Under the common law the owner of the surface possesses all mining rights as well, unless these have been reserved by some previous owner of the property. From very ancient times deposits of gold and silver have in most countries been held as the property of the crown. In public or government land the minerals as well as surface belong to the state, and not infrequently these rights have been separated by law and granted or otherwise disposed of to different owners. It is to the public interest that deposits of mineral should not be permitted to remain idle and undeveloped. This has been recognized from the earliest times, and laws have been framed in all countries for the encouragement of mining enterprise. In many cases the state or the ruler has sought to obtain a share in the profits of mining, or even to work mines for the individual profit of the ruler or of the state. But in most cases it has been found better policy for the state to divest itself of all interest in mining property, and to extend all possible encouragement to those who undertake the development of the mineral wealth of the nation. The mining laws of most civilized states grant the right of free prospecting over the public lands, protect the rights of the discoverer of the mineral deposit during the period of exploration, and provide for the acquisition of mineral property on favourable terms. Striking examples of the far-reaching effect of such laws is shown in the history of the Rocky Mountain region and western coast of the United States, the colonization and development of Australia, and the development of Alaska.

MINION, a favourite, pet or spoiled person. The word is adapted from the Fr. *mignon* (Ital. *mignone*), of which the origin is doubtful. Connexions with the O.H. Ger. *minna*, love, and with a Celtic root *min-*, meaning small, have been suggested. "Minion" is chiefly applied in a derogatory sense to the "creatures" of a royal court, and thus has been used of the favourites of Edward II. and James I. of England, and of Henry III. of France. In the sense pretty, delicate, dainty, the French form *mignon* or *mignonne* is often used in English. During the 17th century "minion" was the name of a type of cannon with a small bore. In typography, it is still used for the type which comes between "nonpareil" and "brevier."

MINISTER (Lat. *minister*, servant), an official title both civil and ecclesiastical. The word *minister* as originally used in the Latin Church was a translation of the Greek *διάκονος*, deacon; thus Lactantius speaks of *presbyteri et ministri*, priests and deacons (*De mort. persecutorum*, No. 15), and in this sense it is still technically used; thus canon vi., Sess. xxiii. of the council of Trent speaks of the hierarchy as consisting "*ex episcopis, presbyteris et ministris.*" But the equivocal character of the word soon led to the blurring of any strictly technical sense it once possessed. Bishops signed themselves *minister* in the spirit of humility, priests were "servants of the altar" (*ministri altaris*), while sometimes the phrase *ministri ecclesiae* was used to denote the clergy in minor orders (see *Lex Bajwar. tit.* 8, quoted in Du Cange). A similar equivocal character attaches to the word minister as used in the Anglican formularies: "Oftentimes it is made to express the person officiating in general, whether priest or deacon; at other times it denoteth the priest alone, as contradistinguished from the deacon" (Burn's *Eccl. Law*, ed. Phillimore, iii. 44). Thus the 33rd canon of 1603 orders that "no bishop shall make any person a deacon and minister both together upon one day." Generally, however, it may be said that in the use of the Church of England "minister" means no more than *executor officii*, a sense in which it was used long before the Reformation. As the most colourless of all official ecclesiastical titles, it is easy to see how the word minister has come to be applied to the clergy of Protestant denominations. The phrase "minister of religion" is wide enough to embrace any evangelical office, and has about it more of the savour of humility than "pastor."

The civil title of minister originates in the same exact sense of servant, *i.e.* servants of the royal household (*ministri aulae regis*). This origin is still clearly traceable in the titles of some ministers in Great Britain, *e.g.* chancellor of the exchequer, first lord of the treasury, and in the official style of "his majesty's servants" applied to all. Practically, however, the word minister has in modern states come to be applied to the heads of the great administrative departments who as such are members of the government. On the continent there are, besides, "ministers without portfolio," *i.e.* ministers who, without being in charge of any special department, are members of the government. In general it is distinctive of constitutional states that any public act of the sovereign must bear the countersignature of the minister responsible for the department concerned. (See the articles MINISTRY and CABINET. For the history and meanings of the word "minister" in diplomacy, see DIPLOMACY.) (W. A. P.)

MINISTRY, the office of a minister (*q.v.*), in all its meanings, political and religious, or the body of persons holding such an office and performing its duties; more particularly the body of persons who, in theory the servants at the head of the state, act as the responsible executive over the whole sphere of government, as in the United Kingdom. On the continent of Europe, on the other hand, the word "ministry" is most usually applied to the responsible head of a particular department together with his subordinates, including the permanent officials or staff. In England, ever since the introduction of monarchical institutions the sovereign has always been surrounded by a select body of confidential advisers to assist the crown in the government of the country. At no period could a king of England act, according to law, without advice in the public concerns of the kingdom; the institutions of the crown of England and the institution of the privy council are coeval. At the Norman Conquest the king's council, or as it is now called, the privy council, was composed of certain members of the aristocracy and great officers of state, specially summoned by the crown, with whom the sovereign usually advised in matters of state and government. In the earlier stages of English constitutional history the king's councillors, as confidential servants of the monarch, were present at every meeting of parliament in order to advise upon matters judicial in the House of Lords; but in the reign of Richard II. the privy council dissolved its judicial connexion with the peers and assumed an independent jurisdiction of its own. It was in the reign of Henry VI. that the king's council first assumed the name of privy council, and it was also during the minority of this sovereign that a select council gradually emerged from the larger body of the privy council, which ultimately became the modern cabinet. Since the Revolution of 1688, and the development of parliamentary government, the privy council has dwindled into comparative insignificance. The power once swayed by the privy council is now exercised by that unrecognized select committee of the council known as the cabinet (*q.v.*). The practice of consulting a few confidential advisers instead of the whole privy council had been resorted to by English monarchs from a very early period; but the first mention of the term cabinet council in contradistinction to privy council occurs in the reign of Charles I., when the burden of state affairs was entrusted to the committee of state which Clarendon says was enviously called the "cabinet council." At first government by cabinet was as unpopular as it was irregular. Until the formation of the first parliamentary ministry by William III. the ministers of the king occupied no recognized position in the House of Commons; it was indeed a moot point whether they were entitled to sit at all in the lower chamber, and they were seldom of one mind in the administration of matters of importance. Before the Revolution of 1688 there were ministers, but no ministry in the modern sense of the word; colleague schemed against colleague in the council chamber, and it was no uncommon thing to see ministers opposing one another in parliament upon measures that in modern times would be supported by a united cabinet. As the change from government by prerogative to government by parliament, consequent upon the Revolution of 1688, developed, and the House of Commons became more and more the centre and force of the state, the advantage of having ministers in the legislature to explain and defend the measures and policy of the executive government began to be appreciated. The public authority of the crown being only exercised through the medium of ministers, it became absolutely necessary that the advisers of the sovereign, who were responsible for every public act of the Crown as well as for the general policy they had been called upon to administer, should have seats in both Houses of Parliament. Still nearly a century had to elapse before political unanimity in the cabinet was recognized as a political maxim. From the first parliamentary ministry of William III. until the rise of the second Pitt, divisions in the cabinet were constantly occurring, and a prime minister had more to fear from the intrigues of his own colleagues than from the tactics of the opposition. In 1812 an attempt was made to form a ministry consisting of men of opposite political principles, who were invited to accept office, not avowedly as a coalition government, but with an offer to the Whig leaders that their friends should be allowed a majority of one in the cabinet. This offer was declined on the plea that to construct a cabinet on "a system of counteraction was inconsistent with the prosecution of any uniform and beneficial course of policy." From that date it has been an established principle that all cabinets are to be formed on some basis of political union agreed upon by the members when they accept office together. It is now also distinctly understood that the members of a cabinet are jointly and severally responsible for each other's acts, and that any attempt to distinguish between a particular minister and his colleagues in such matters is unconstitutional.

During the 19th century the power of ministers was greatly extended, and their duties became more distinctly marked out. As now interpreted, the leading principles of the British constitution are the personal irresponsibility of the sovereign, the responsibility of ministers, and the inquisitorial and controlling power of parliament. At the head of affairs is the prime minister (*q.v.*), whose duties are more general than departmental, and the other members of the administration, whose work is exemplified by the titles of their offices (the more important of which are treated separately), are the lord high chancellor, the lord president of the council, the lord privy seal, the first lord of the treasury, the five secretaries of state (home, foreign affairs, colonies, war, India), the chancellor of the exchequer, the secretary for Scotland, the chief secretary to the lord-lieutenant of Ireland, the postmaster-general, the presidents of the board of trade, the local government board, the board of agriculture and the board of education (all of which were originally committees of the privy council), the chancellor of the duchy of Lancaster and the first lord of the admiralty. These are the more important members of the administration, and they are generally in the cabinet. The subordinate members of the administration, some of whom are occasionally invited to join the cabinet, while others are never in it, are the parliamentary and financial secretary to the admiralty, the parliamentary under-secretaries of the home, foreign, war, colonial and India offices, the board of trade, local government and board of education, the junior lords of the treasury (assistant "whips"), the financial secretary and patronage secretary to the treasury (the senior "whip"), the first commissioner of works, the paymaster-general, and the attorney-general and solicitor-general. There are in addition the lord advocate and the solicitor-general for Scotland, the lord-lieutenant and lord chancellor of Ireland (who are sometimes members of the cabinet), and the attorney-general and solicitor-general for Ireland.

TABLE OF LORD TREASURERS OR FIRST LORDS OF THE TREASURY

[The title was at first lord treasurer, except when the treasury was put in commission. Ultimately special rank was given to one of the commissioners as first lord of the treasury. From the time of the earl of Essex (1679) the name given is that of the first lords, with the exception of the three printed in italics. In modern times the first lord of the treasury has usually, but not invariably, been the head of the government or prime minister. A list of the Prime Ministers is given in the article PRIME MINISTER.

1603. Lord Buckhurst, cr. Earl of Dorset 1604.
1608. Earl of Salisbury.
1612. Earl of Northampton and others. (Commissioners.)
1614. Earl of Suffolk.
1618. Archbishop Abbot and others. (Commissioners.)
1620. Sir H. Montagu, cr. Viscount Mandeville 1620.
1621. Lord Cranfield, cr. Earl of Middlesex 1622.
1624. Sir J. Ley, cr. Lord Ley 1625, and Earl of Marlborough 1626.
1628. Lord Weston, cr. Earl of Portland 1633.
1635. Archbishop Laud and others. (Commissioners.)
1636. W. Juxon, Bishop of London.
1641. Sir E. Littleton and others. (Commissioners.)
1643. Lord Cottington.
1649. Interregnum.
1660. Sir E. Hyde and others. (Commissioners.)
1660. Earl of Southampton.
1667. Duke of Albemarle and others. (Commissioners.)
1672. Lord Clifford.
1673. Viscount Dunblane, cr. Earl of Danby 1674.
1679. Earl of Essex.
1679. Lord Hyde, cr. Earl of Rochester 1682.
1684. Lord Godolphin.
1687. Lord Bellasyse.
1689. Earl of Monmouth.
1690. Viscount Lonsdale.
1690. Lord Godolphin.
1697. C. Montagu, cr. Earl of Halifax 1700.
1699. Earl of Tankerville.
1700. Lord Godolphin.
1701. Earl of Carlisle.
1702. *Lord Godolphin.*
1710. Earl Poulett.
1711. *Earl of Oxford.*
1714. *Duke of Shrewsbury.*
1714. Earl of Halifax.
1715. Earl of Carlisle.
1715. Sir R. Walpole.
1717. Lord Stanhope.
1718. Earl of Sunderland.
1721. Sir R. Walpole.
1742. Earl of Wilmington.
1743. H. Pelham.
1754. Duke of Newcastle.
1756. Duke of Devonshire.
1757. Duke of Newcastle.
1762. Earl of Bute.
1763. G. Grenville.
1765. Marquess of Rockingham.
1766. Duke of Grafton.
1770. Lord North.
1782. Marquess of Rockingham.
1782. Earl of Shelburne.
1783. Duke of Portland.
1783. W. Pitt.
1801. H. Addington.
1804. W. Pitt.
1806. Lord Grenville.
1807. Duke of Portland.
1807. S. Perceval.
1812. Earl of Liverpool.
1827. G. Canning.
1827. Viscount Goderich.
1828. Duke of Wellington.
1830. Earl Grey.
1834. Viscount Melbourne.
1834. Sir R. Peel.
1835. Viscount Melbourne.
1841. Sir R. Peel.
1846. Lord J. Russell, cr. Earl Russell 1861.
1852. Earl of Derby.
1852. Earl of Aberdeen.
1855. Viscount Palmerston.
1858. Earl of Derby.
1859. Viscount Palmerston.
1865. Earl Russell.
1866. Earl of Derby.
1868. B. Disraeli.
1868. W. E. Gladstone.
1874. B. Disraeli, cr. Earl of Beaconsfield 1876.
1880. W. E. Gladstone.
1885. Sir Stafford Northcote, cr. Earl of Iddesleigh 1885 (prime minister, Marquess of Salisbury).
1886. W. E. Gladstone.
1886. Marquess of Salisbury.
1887. W. H. Smith (prime minister, Lord Salisbury).
1891. A. J. Balfour (prime minister, Lord Salisbury).
1892. W. E. Gladstone.
1894. Earl of Rosebery.
1895. A J. Balfour (prime minister, Lord Salisbury till 1902).
1905. Sir H. Campbell-Bannerman.
1908. H. H. Asquith.

TABLE OF LORD CHANCELLORS (C.) OR LORD KEEPERS (L.K.)

1603. Sir T. Egerton, L.K., cr. Lord Ellesmere 1603, and Viscount Brackley 1616.
1617. Sir F. Bacon, L.K., cr. Lord Verulam 1618, and Viscount St Albans 1621.
1621. J. Williams, Bishop of Lincoln, L.K.
1625. Sir T. Coventry, L.K., cr. Lord Coventry 1628.
1640. Sir J. Finch, L.K., cr. Lord Finch 1640.
1641. Sir E. Littleton, L.K., cr. Lord Lyttelton 1641.
1645. Sir R. Lane, L.K.
1649. Interregnum.
1660. Sir E. Hyde, C., cr. Lord Hyde 1660, and Earl of Clarendon 1661.
1667. Sir O. Bridgeman, L.K.
1672. Earl of Shaftesbury, C.
1673. Sir H. Finch, L.K., cr. Lord Finch 1674, C. 1675, cr. Earl of Nottingham 1681.
1682. Sir F. North, L.K., cr. Lord Guilford 1683.
1685. Lord Jeffreys, C.
1690. Sir J. Maynard and others. (Commissioners.)
1690. Sir J. Trevor and others. (Commissioners.)
1693. Sir J. Somers, L.K., C., cr. Lord Somers 1697.
1700. Sir N. Wright, L.K.
1705. W. Cowper, L.K., cr. Lord Cowper 1706, C. 1707.
1710. Sir T. Trevor and others. (Commissioners).
1710. Sir S. Harcourt, L.K., cr. Lord Harcourt 1711, C. 1713.
1714. Lord Cowper, C.
1718. Sir R. Tracy and others. (Commissioners.)
1718. Lord Parker, C., cr. Earl of Macclesfield 1721.
1725. Sir J. Jekyll and others. (Commissioners.)
1725. Lord King, C.
1733. Lord Talbot of Hensol, C.
1737. Lord Hardwicke, C., cr. Earl of Hardwicke 1754.
1756. Sir J. Willes and others. (Commissioners.)
1757. Sir R. Henley, L.K., cr. Lord Henley and C. 1760, Earl of Northington 1764.
1766. Lord Camden, C.
1770. Charles Yorke, C.
1770. Sir S. S. Smythe and others. (Commissioners.)
1771. Lord Apsley, C., succeeded as Earl Bathurst 1775.
1778. Lord Thurlow, C.
1783. Lord Loughborough and others. (Commissioners.)
1783. Lord Thurlow, C.
1792. Sir J. Eyre and others. (Commissioners.)
1793. Lord Loughborough, C., cr. Earl of Rosslyn 1801.
1801. Lord Eldon, C.
1806. Lord Erskine, C.
1807. Lord Eldon, C.
1827. Lord Lyndhurst, C.
1830. Lord Brougham, C.
1834. Lord Lyndhurst, C.
1835. Sir C. C. Pepys and others. (Commissioners.)
1836. Lord Cottenham, C.
1841. Lord Lyndhurst, C.
1846. Lord Cottenham, C.
1850. Lord Langdale and others. (Commissioners.)
1850. Lord Truro, C.
1852. Lord St Leonards, C.
1852. Lord Cranworth, C.
1858. Lord Chelmsford, C.
1859. Lord Campbell, C.
1861. Lord Westbury, C.
1865. Lord Cranworth, C.
1866. Lord Chelmsford, C.
1868. Lord Cairns, C.
1868. Lord Hatherley, C.
1872. Lord Selborne, C.
1874. Lord Cairns, C., cr. Earl Cairns 1878.
1880. Lord Selborne, C., cr. Earl of Selborne 1882.
1885. Lord Halsbury, C.
1886. Lord Herschell, C.
1886. Lord Halsbury, C.
1892. Lord Herschell, C.
1895. Lord Halsbury, C., cr. Earl of Halsbury 1898.
1905. Lord Loreburn, C.

TABLE OF SECRETARIES OF STATE

[The substitution of two secretaries for one was the consequence of the increase of business. There was no distinction of departments, each secretary taking whatever work the king saw fit to entrust him with During the reigns of the first two Stuarts, however, there was a tendency to entrust one secretary with the correspondence with Protestant states and their allies, and the other with the correspondence with Catholic states. Probably in the reign of Charles II., and certainly as early as 1691, two departments, the Northern and the Southern, were instituted. In 1782 the departments were changed to Home and Foreign. A third secretary of state was appointed in 1794, and he was called the Secretary for War and the Colonies from 1801 to 1854, when the work was divided, and the War and Colonial Secretaryships were instituted. The Secretary of State for India was appointed in 1858.]

1603.	Sir R. Cecil, cr. Lord Cecil 1603, Viscount Cranborne 1604, Earl of Salisbury 1605	
1612.	Vacant.	
1614.	Sir R. Winwood.

MINK, a name for certain large species of the zoological genus *Putorius* (Polecat), distinguished by slight structural modifications and semi-aquatic habits. The two best-known species, so much alike in size, form, colour and habits that, although they are widely separated geographically, some zoologists question their specific distinction, are *P. lutreola*, the *Nörz* or *Sumpfotter* (marsh-otter) of eastern Europe, and *P. vison*, the mink of North America. The former inhabits Finland, Poland and the greater part of Russia, though not found east of the Ural Mountains. Formerly it extended westward into central Germany, but it is now very rare, if not extinct, in that country. The latter is found in places which suit its habits throughout the whole of North America. Another form, *P. sibiricus*, from eastern Asia, of which much less is known, appears to connect the true minks with the polecats.

The name may have originated in the Swedish *maenk* applied to the European animal. Captain John Smith, in his *History of Virginia* (1626), at p. 27 speaks of "Martins, Powlecats, Weesels and Minkes," showing that the animal must at that time have been distinguished by a vernacular appellation from its congeners. By later authors, as Lawson (1709) and Pennant (1784), it is often written "Minx." For the following description, chiefly taken from the American form (though almost equally applicable to that of Europe) we are mainly indebted to Dr Elliott Coues's *Fur-bearing Animals of North America*, 1877.

In size it much resembles the English polecat—the length of the head and body being usually from 15 to 18 in., that of the tail to the end of the hair about 9 in. The female is considerably smaller than the male. The tail is bushy, but tapering at the end. The ears are small, low, rounded, and scarcely project beyond the adjacent fur. The pelage consists of a dense, soft, matted under fur, mixed with long, stiff, lustrous hairs on all parts of the body and tail. The gloss is greatest on the upper parts; on the tail the bristly hairs predominate. Northern specimens have the finest and most glistening pelage; in those from southern regions there is less difference between the under and over fur, and the whole pelage is coarser and harsher. In colour different specimens present a considerable range of variation, but the animal is ordinarily of a rich dark brown, scarcely or not paler below than on the general upper parts; but the back is usually the darkest, and the tail is nearly black. The under jaw, from the chin about as far back as the angle of the mouth, is generally white. In the European mink the upper lip is also white, but, as this occasionally occurs in American specimens, it fails as an absolutely distinguishing character. Besides the white on the chin, there are often other irregular white patches on the under parts of the body. In very rare instances the tail is tipped with white. The fur is important in commerce.

The principal characteristic of the mink in comparison with its congeners is its amphibious mode of life. It is to the water what the other weasels are to the land, or martens to the trees, being as essentially aquatic in its habits as the otter, beaver, or musk-rat, and spending perhaps more of its time in the water than it does on land. It swims with most of the body submerged, and dives with perfect ease, remaining long without coming to the surface to breathe. It makes its nest in burrows in the banks of streams, breeding once a year about the month of April, and producing five or six young at a birth. Its food consists of frogs, fish, fresh-water molluscs and crustaceans, as well as mice, rats, musk-rats, rabbits and small birds. In common with the other animals of the genus, it has a very peculiar and disagreeable effluvium, which, according to Dr Coues, is more powerful, penetrating and lasting than that of any animal of the country except the skunk. (W. H. F.)

MINNEAPOLIS, the largest city of Minnesota, U.S.A., and the county-seat of Hennepin county, situated on both banks of the Mississippi river at the Falls of St Anthony and immediately above St Paul. Pop. (1870), 13,066; (1880), 46,887; (1890), 164,738; (1900), 202,718; (1910 census) 301,408. Of the total population in 1900, those of foreign parentage (both parents foreign-born) numbered 118,946, and there were 61,021 of foreign birth, including 20,035 Swedes, 11,532 Norwegians, 7335 Germans, 5637 English-Canadians, 3213 Irish, 2289 English, 1929 Russians, 1706 French-Canadians and 1133 Austrians. Minneapolis is served by the Chicago, Burlington & Quincy, the Chicago, Great Western, the Chicago, Milwaukee & St Paul, the Chicago & Northwestern, the Chicago, Rock Island & Pacific, the Great Northern, the Minneapolis & St Louis, the Minneapolis, St Paul & Sault Sainte Marie, and the Northern Pacific railways. It has also three terminal switching lines and the belt line of the Minnesota Transfer Company, serving both Minneapolis and St Paul. With St Paul, which is served by the same system of railways, Minneapolis is the chief railway centre of the Northwest and one of the greatest in the United States, being the principal gateway to the commerce of the Canadian and Pacific north-west. There are a Union passenger station, and separate stations for the Chicago, Milwaukee & St Paul, the Chicago, Great Western and the Minneapolis & St Louis railways.

The city is situated on a high plateau (800–850 ft. above sea-level) above the river, and covers an area of about 53 sq. m. It has an extensive system of boulevards, parkways and parks (aggregating 2465 acres in 1908). Among the parks are Loring, near the centre of the city, in which is a statue of Ole Bull; Lyndale, in the south-west part of the city; Interlachen, just north-west of Lyndale; Glenwood, in the west of the city; Van Cleve, Logan, Windom and Columbia in the part of the city east of the Mississippi river; Riverside, on the south-west bank of the Mississippi; and Minnehaha Park, in which are the Minnehaha Falls, a beautiful cascade of the Minnehaha Creek (the outlet of Lake Minnetonka), near the Mississippi, with a fall of 50 ft., well known from Longfellow's poem "Hiawatha." The numerous small lakes in the city (there are about 200 lakes in Hennepin county) have been incorporated in the park system; among them are Lake Harriet (353 acres; in Lake Harriet Park), Lake Calhoun (on which are extensive public baths), Lake Amelia (295 acres), Lake of the Isles (100 acres), Cedar Lake, Powder Horn Lake (in the park of that name) and Sandy Lake (in Columbia Park). Adjoining Minnehaha Park are the grounds (51 acres, given to the state by the city) and buildings of the Minnesota state soldiers' home (1887); and 2 m. beyond the Falls, at the junction of the Minnesota and Mississippi rivers, is the Fort Snelling Military Reservation (1819). Seven miles south-west of the limits of the city is Lake Minnetonka, one of the most famous summer resorts in the Northwest, a beautiful body of water 15 m. long, with a shore line of 150 m. encircled by undulating wooded hills. Among the most fashionable streets are Mount Curve, Clifton and Park avenues, all in the "West Division" or south-western quarter of the city. The streets in all parts of the city are of exceptional width and heavily shaded in the residential districts. There are handsome residential suburbs. The court-house and city-hall, constructed of red Minnesota granite and completed in 1902 at a cost of about $3,500,000, is one of the finest municipal buildings in America. Other prominent buildings are the Masonic Temple, the Chamber of Commerce, the Lumber Exchange, the Bank of Commerce, the Auditorium; the buildings of the Metropolitan Life (formerly the Guaranty), the Security Bank, the Northwestern National Bank, the First National Bank, the Andrus, the New York Life, and the Young Men's Christian Association; Hotel Radisson and West Hotel. Minneapolis is the see of a Protestant Episcopal bishopric. On the east side of the river are the buildings of the university of Minnesota (*q.v.*). In Minneapolis are the Minneapolis College of Physicians and Surgeons (1883), the medical school of Hamline University; Augsburg Seminary (Norwegian Lutheran, 1869), the United Church Seminary (1890), the Minnesota College (Swedish, 1905), the Minneapolis Normal School for Kindergartners, the Froebellian Kindergarten Normal School, Graham Hall and Stanley Hall, the Minneapolis School of Music, Oratory and Dramatic Art, and the Northwestern Conservatory of Music. Between Minneapolis and St Paul are the main buildings of Hamline University (Methodist Episcopal, co-educational, 1854). The public library (more than 180,000 volumes in 1908) grew out of a private library, the Athenaeum (1860), was reorganized by Herbert Putnam (librarian from 1887 to 1891), and has several branches, the most notable of which is the Pillsbury Library (1904) on the east side; in its main building (Hennepin Avenue and 10th Street) are the offices of the Minnesota Academy of Natural Sciences (1873), which, with the Society of Fine Arts, assisted in erecting the building in 1884. Among the hospitals and charitable institutions are the Minneapolis city hospital, the state hospital for crippled and deformed children, and Asbury Methodist, the Northwestern, the Deaconess', the Swedish, the St Mary's, the Maternity and the St Barnabas hospitals, Bethany Home, the Catholic orphan asylum, the Washburn orphans' home, the Pillsbury House (1906) where settlement work is carried on by the Plymouth Congregational Church, and several free dispensaries. The first newspaper in the city was the St Anthony *Express*, which began publication in 1851; it is no longer in existence. In 1906 the city had, in addition to numerous weekly and monthly periodicals (English, Norwegian-Danish, Swedish, German, French), four dailies, the *Tribune* (1867), the *Journal* (1878), and the *News* (1903), all in English, and the *Tidende* (Norwegian-Danish), established as a weekly in 1851.

The Mississippi river, which here has an average width of about 1200 ft., is crossed by 17 bridges (9 highway and 8 railway bridges). The Federal government undertook to deepen the channel by dredging and by making two dams and two locks between the Chicago, St Paul, Minneapolis & Omaha railway bridge in St Paul and the Washington Avenue bridge in Minneapolis—a distance of 11·4 m.—from 2 or 3 ft. to 6 ft., and to make the river regularly navigable as far as the Washington Avenue bridge, Minneapolis; the project, first adopted in 1894 and modified in 1907, was 70% completed in July 1908, and up to that time $1,061,397 had been spent on the work. The enormous water-power of the Falls of St Anthony, yielding about 40,000 h.p., has been the principal factor in making Minneapolis a great manufacturing centre. The rapid erosion of the soft limestone bed at one time threatened the destruction of the power, but this has been prevented by an enormous apron and an artificial concrete floor (completed in 1879). Additional water-power (25,000 h.p.) is derived from Taylor's Falls on the St Croix river. The proximity of the rich wheatfields of the north-west, and the extensive timber forests, have made Minneapolis the greatest lumber and flour centre in the world. The importance of the flour manufacturing industry was originally due to the excellent water-power available, and dates from the introduction of improved roller-mill methods in the early 'seventies, although there were successful mills in operation twenty years earlier. The enormous flour-mills of Minneapolis (22 in 1907) are perhaps the most interesting sights of the city. Their aggregate daily capacity is over 80,000 barrels, the largest of them having a capacity of 15,000 to 16,500 daily. In 1905 the value of the city's flour and grist mill products was $62,754,446, 51·6 % of the total value of the city's factory product, and 8·8 % of the value of the flour and grist mill products of the entire United States. Food preparations were valued in 1905 at $1,361,492. Minneapolis is also the greatest primary wheat market in the world, its 40 or more elevators (of which those of the Washburn-Crosby Company, erected in 1907, are the largest) having a net capacity of about 35,000,000 bushels, and handling more than 90,000,000 bushels in 1908. Its commerce in other grains is also extensive; in the amount of barley received and shipped Minneapolis surpasses any other city in the United States, and in receipts and shipments of rye is second only to Chicago. The Mississippi river above Minneapolis is made to serve, by means of a series of extensive log-booms, as the principal source of supply to the great saw-mills, of which there are here some of the largest in the world, with a combined capacity of 3,500,000 ft. a day, and with an average annual cut of 575,000,000 ft. The total value of the lumber products in 1905 was $9,960,842 (lumber and timber, $5,816,726; planing-mill products, including sash, doors and blinds, $4,144,116). Other important manufactures with the product-value of each in 1905 were malt liquors ($1,185,525), foundry and machine shop products ($2,820,697), structural iron-work ($1,991,771), steam railway car construction and repairing ($2,027,248), patent medicines ($1,715,889), furniture ($1,238,324), cooperage ($1,415,360), and hosiery and knit goods ($957,455). The total value of the factory product was $94,407,774 in 1900, and $121,593,120 in 1905, an increase of 28·8 %; in 1905 the value of the factory product was 39·5 % of that of the entire state.

Minneapolis is governed under a charter adopted in 1872 (when St Anthony and Minneapolis were consolidated) and frequently amended. It provides for the election of a mayor, treasurer and comptroller for two-years terms; for elected boards of control for library, parks and education, and for a unicameral city council, half of which is chosen every two years for a term of four years. The mayor, whose veto may be nullified by an adverse vote of two-thirds of the council, has very limited appointing powers, the head of the police department being the most important of his appointees. The city council elects the city clerk, city attorney, city engineer, chief of the fire department and most of the minor officers. Under a provision of the charter adopted in 1887 saloons are not permitted outside the "patrol limits of the business district"; so that there are no saloons in the residential districts of the city. The municipality owns the waterworks system, the water supply being obtained from the Mississippi river.

History.—The first recorded visit of a European to the site of Minneapolis was that of Father Louis Hennepin, the French Jesuit missionary, who discovered and named the Falls of St Anthony in 1680; but it is almost certain that he was preceded by some of the adventurous *coureurs des bois*, few of whom left records of their extensive wanderings, and Radisson and Groseilliers seem to have visited this region two decades before Hennepin. The land on which the city lies, being divided by the Mississippi river, was for many years under different sovereignties, the east side becoming United States territory at the close of the War of Independence, while the west side, after being under Spanish and French rule, did not become a part of the United States until the purchase of Louisiana in 1803. In 1766 the site was visited by the American traveller, Jonathan Carver, and in 1805 by Lieut. Zebulon M. Pike; the military reserve which Pike bought from the Indians included a greater portion of the west side of the present city. After the erection of Fort St Anthony (1819; later called Fort Snelling), a water-power saw-mill was erected (1822) to saw lumber for the fort on the east bank of the river at the Falls of St Anthony. Later flour was also ground in this mill, which thus became the forerunner of the greatest of the city's industries. Gradually as the Indian land titles became extinguished the east bank was settled. The first settlement on the west bank was made by Colonel John H. Stevens in 1850, but the land was not opened to settlers until 1855. The village of St Anthony, on the east side of the river, was incorporated in 1855; Minneapolis, on the west bank, was incorporated in 1856. St Anthony became a city in 1860, and Minneapolis, which then had only 2564 inhabitants, soon outstripped its neighbour after the Civil War, and received a city charter in 1867. In 1870 Minneapolis alone had 13,066 inhabitants (18,079 with St Anthony), and in 1872 the two cities were united under the name of Minneapolis. The Republican National Convention met in Minneapolis in 1892 and renominated President Benjamin Harrison.

MINNESINGERS (Ger. *Minnesänger* from *Minne*, love), the name given to the German lyric poets of the 12th and 13th centuries. The term *Minnesang*, strictly applicable to the poems expressing the homage (*Minnedienst*) rendered by the knight to his mistress, is applied to the whole body of lyric poetry of the period, whether dealing with love, religion or politics. The idea of *amour courtois*, with its excessive worship of woman, its minute etiquette and its artificial sentiment, was introduced into German poetry from Provençal literature; but the German *Minnesang* was no slavish imitation of the poetry of the troubadours. Its tone was, on the whole, far healthier and more sincere, reflecting the difference between the simple conditions of German life and the older and corrupt civilization of Provence. The minnesinger usually belonged to the lower ranks of the nobility, and his verses were addressed to a married woman, often above him in rank; consequently the commonest lyric themes are the lover's hopeless devotion and complaints of the lady's cruelty, expressed with a somewhat wearisome iteration. That real passion was sometimes present may be safely assumed, but it was not within the rules of the game, which corresponded fairly closely to the later sonneteering conventions. The poet was not permitted to give the lady's name, or to betray her identity; and a direct expression of passion would also have contravened the rules. The poems were from the first sung in open court to a melody (*Weise*) of the poet's own composing, with the accompaniment of a fiddle or small harp. That the minnesinger was no improvisatore is evident from the complicated forms of his verse, which were partly borrowed from the Provençal, but possibly owed something to the Latin rhymed verse[1] of the wandering scholars. The older songs consisted of a single strophe cast in three divisions, two (known as *Stollen* or doorposts) identical in form, stating and developing the argument, the third (*Abgesang*) of different form, giving the conclusion. Later on, two or more strophes were used in a single poem, but the principle of their structure was retained. In this form were cast the *Tagelied*, a dialogue describing the parting of lovers at dawn; and the crusading song. Side by side with these existed the *Spruch*, written in a single undivided stanza, destined for recitation and often cast in the form of a fable. The lay (*Leich*) was written in unequal strophes, each formed of two equal divisions. It was applied in the first instance to sacred lyrics, and was first used in love poems by the Alsatian minnesinger Ulrich von Gutenberg.

---

[1] See the *Carmina Burana*, ed. J. A. Schmeller, 4th ed., Breslau, 1904.

The origin of the native lyric, which flourished especially in Austria and Bavaria, is perhaps to be sought in the songs which accompanied dancing. These were not necessarily love songs, but celebrated the coming of spring, the gloom of winter &c., the commonplaces of *Minnesang* throughout the two centuries of its existence. The older lyrics, which date from the middle of the 12th century, are simple in form and written in the ordinary epic metres. The earliest minnesinger whose name has come down to us is Der von Kürenberg (*fl.* *c.* 1160), a scion of an Austrian knightly family whose castle lay on the Danube, west of Linz. These songs, however, contradict the root idea of *Minnedienst*, since the lady is the wooer, and the poet, at the most, an acquiescent lover. They take the form of laments for an absent lover, complaints of his faithlessness and the like. Among the other Austrian and south German lyrists who show small trace of foreign influence was Dietmar von Aist (d. *c.* 1171), though some of the songs attributed to him seem to be of later date. While the love-song remained in the hands of noble singers, the *Spruch* was cultivated by humbler poets. The elder of the two or three poets concealed under the name of Spervogel was a wandering singer who found patronage at the court of the burgraves of Regensburg, one of whom himself figures among the earlier minnesingers.

The characteristic period of German *Minnesang* begins at the close of the 12th century with the establishment of the Provençal tradition in western Germany through the poems of Heinrich von Veldeke and Friedrich von Hausen. National elements abound in Veldeke's songs, although the *amour courtois* dominates the whole; Friedrich von Hausen (d. 1190) followed Provençal models closely. The long crusading song *Sie darf mich des Zîhen niet*, is a good example of his powers. A close disciple of the troubadours Peire Vidal and Folquet de Marseille was the Swiss Count Rudolf von Fenis.[1] The greatest name among the earlier minnesingers is that of Heinrich von Morungen, a Thuringian poet who lived on in popular story in the ballad of "The Noble Moringer." He brought great imaginative power to bear on the common subjects of *Minnesang*, and his poetry has a very modern note. The formal art and science of *Minnesang* reached full development in the subtle love-songs of Reinmar, the Alsatian "nightingale of Hagenau." Uhland aptly called him the "scholastic philosopher of unhappy love." As a metrist he developed a greater correctness of rhyme, and a better handling of German metres. He became a member of the court of Duke Leopold V. (d. 1194) of Austria, and there Walther von der Vogelweide (*q.v.*) was first his disciple, and then perhaps his rival. Walther, the greatest of medieval German lyric poets, had Reinmar's technical art, but in feeling was more nearly allied to Morungen. He raised the *Spruch* to the dignity of a serious political poem, which proved a potent weapon against the policy of Innocent III. In 1202 at the court of Hermann, landgrave of Thuringia, he met Wolfram von Eschenbach, who is said to have taken part in the tourney of poets known as the *Wartburgskrieg*, made world-famous through Wagner's *Tannhäuser*. The *Tagelieder* of Wolfram give him a high place in *Minnesang*, although his fame, like that of Heinrich von Veldeke and Hartmann von Aue, chiefly rests on his epics. A new style—called by Lachmann *höfische Dorfpoesie*—was marked out by Neidhart von Reuental (d. *c.* 1240), who belonged to the lesser Bavarian nobility. He wrote songs to accompany the dances of the village beauties, and comic and realistic descriptions of village life to please the court. He was acknowledged by the Meistersinger as one of the twelve masters of song. Nevertheless, with him the decadence may be said to have begun.

The Styrian poet Ulrich von Lichtenstein (d. *c.* 1275) unconsciously caricatured chivalry itself by his *Frauendienst*, in which he relates the absurd feats which he had undertaken at his lady's command, while Steinmar (*fl.* 1276) deliberately parodied court poetry in his praises of rustic beauty and good living. In the lays, songs and proverbs of Tannhäuser something of both elements, of the court and the village, is to be found. He seems to have lived as a wandering singer until 1268, and there very soon grew up round his name the Tannhäuser myth which has so little foundation in his life or poetry. The Austrian poet Reinmar von Zweter (d. *c.* 1260) left some hundreds of *Sprüche* political or social in their import. Among the princes who practised *Minnesang* were the emperor Henry VI., though the two songs preserved under his name are of doubtful authenticity, Duke Henry IV. of Breslau (*fl.* 1270–1290), King Wenceslaus II. of Bohemia, the margrave Otto IV. of Brandenburg, Wizlaw IV., prince of Rügen and the unhappy Conradin, the last of the house of Hohenstaufen, beheaded by the order of Charles of Anjou before he reached his seventeenth year.

The didactic motive came more and more to the front in the 13th century. The wandering Swabian poet Marner (d. *c.* 1270) cultivated especially the *Spruch*, laughed at the Provençal and courtly tradition, and there is no very great step from his learning and his feuds to the conditions of *Meistersang*. Heinrich von Meissen (1250–1319), known as "Frauenlob" ("ladies' praise"), was one of the last minnesingers, and his pedantry and virtuosity entitle him to be called the first meistersinger.

BIBLIOGRAPHY.—The chief MSS. containing the work of the 300 or more minnesingers whose work has been partially preserved, are the old Heidelberg MS. (13th century), the Weingarten—Stuttgart MS. (14th century) and the Great Heidelberg MS. (14th century), formerly known as the Manasse MS. This last is the most comprehensive of all. The collection on which it is based was made by Rüdiger Manasse (d. 1304) and his son Johannes at Zürich. It is quaintly illustrated with imaginary portraits of the poets (that of Hartmann von Aue in full armour with closed vizor!), and pictures of their coats of arms. It was printed by F. Pfaff (Heidelberg, 1899). The completest collection of the minnesingers' verses is F. H. von der Hagen, *Deutsche Liederdichter des zwölften, dreizchnten und vierzehnten Jahrhunderts* (4 vols., Leipzig, 1838), vol. iv. of which contains biographical matter and a discussion of the music; K. Lachmann and M. Haupt, *Des Minnesangs Frühling* (3rd ed., edited F. Vogt, Leipzig, 1882) is a collection of the minnesingers earlier than Walther von der Vogelweide; there is a comprehensive selection of 97 minnesingers by Karl Bartsch, *Deutsche Liederdichter des zwölften bis vierzehnten Jahrhunderts* (ed. W. Golther, Berlin 1901) with bio-bibliographical account of individual minnesingers; see also F. Pfaff, *Der Minnesang der 12 bis 14 Jahrhunderts*, pt. i. (Stuttgart, 1892). English translations of early German lyrics are F. C. Nicholson, *Old German Love Songs*, translated from the minnesingers of the 12th to 14th centuries (London, 1907). See also WALTHER V. D. VOGELWEIDE.

Of historical and critical work on the minnesingers, see K. Goedeke, *Geschichte der deutschen Dichtung*, vol. i. (Dresden, 1881); H. Paul, *Grundriss der germanischen Philologie*, vol. ii. (Strassburg, 2nd ed., 1901), where further references will be found; also A. E. Schönbach, *Die Anfänge des deutschen Minnesanges* (Graz, 1898); F. Grimme, *Geschichte der Minnesänger*, vol. i. Falke, *Die ritterliche Gesellschaft im Zeitalter des Frauencultus* (Berlin, no date).

MINNESOTA, a North Central State of the United States of America. It is bounded on the S. by Iowa, on the W. by South and North Dakota—the Red River (commonly called the Red River of the North) separating it from the latter state—on the N. by the Canadian provinces of Manitoba and Ontario, being separated from the latter by the Lake of the Woods, Rainy River and Rainy Lake, and certain of their tributaries and outlets, and on the E. by Lake Superior and by Wisconsin, from which it is separated for the greater part of the distance by the Mississippi and St Croix rivers. It is the tenth state in size in the Union, with a total area of 84,682 sq. m., of which 3824 sq. m. are water surface.[2] From north to south it is about 400 m. in length, extending from 43° 30′ to 49° 23′ 55″ N. lat., and from east to west its width is about 354 m., lying between long. 89° 29′ and 97° 15′ W.

The north-east part of the state is included in the Great Lakes Province, and the southern and western parts are in the Prairie Plains Province. The whole area of the state was formerly a complexly folded mountainous region of strong relief, which was afterwards worn down to a more nearly level surface, except in the extreme north-east corner, where ridges of harder rock resisted erosion. Marine deposits were laid down over the south of the state after a submergence of the region; an uplift afterwards made of these deposits a coastal plain. The rather level surface of the "worn down mountains" of the north of the state and the coastal plain beds of the southern and western parts are now dissected by rivers, which make most of the state a rolling or hilly country, without strong relief. The average elevation is about 1275 ft. above sea-level or 600 ft. above the surface of Lake Superior. An extensive water-parting in the north central part of the state, an elevation whose inclination is almost imperceptible, determines the course of three great continental river systems. From this central elevation the land slopes off in all directions, rising again in the extreme north-east corner, where the rugged granite uplift in Cook county, known as the Misquah Hills, reaches an altitude of 2230 ft., the highest point in the state; and in the south-west corner, where an altitude of 1800 ft. is reached in the Coteau des Prairies. Only in the valleys of the Red, Minnesota and Mississippi rivers does the elevation fall below 800 ft. In the southern and central portions of the state open rolling prairies interspersed with groves and belts of oak and other deciduous hard-wood timber predominate. A little north of the centre the state is traversed from north-west to south-east by the extensive forest known as the "Big Woods," in which also oak occurs most frequently. In the northern part of the state the great pine belt stretches from the head of Lake Superior westward to the confines of the Red River Valley, while along the north border and in the north-east the forest growth is almost exclusively tamarack and dwarf pine. More than three-fourths of the area of the state is arable, the small percentage of non-arable land lying principally in the north-eastern regions, which afford compensation in the form of rich mineral deposits. Of the three great continental river systems above mentioned, the Red River and its tributaries drain the western and west central slope northward through Lake Winnipeg into Hudson Bay; the other two being the St Lawrence system, to which the St Louis River and its branches and several smaller streams flowing into Lake Superior contribute their waters by way of the Great Lakes and the Mississippi, which with its tributaries drains about two-thirds of the state into the Gulf of Mexico. A few rivers in the south drain into the Mississippi through Iowa, while a smaller area in the extreme north is drained through the Lake of the Woods and Rainy Lake into Hudson Bay. These river systems serve the threefold purpose of drainage, providing water communications (there being about 3000 m. of navigable waters in the state), and, by falls and rapids caused by glacial displacement of rivers, furnishing a magnificent volume of water-power. The Mississippi river, which flows for about 800 m. within or along the borders of the state, has its principal sources in and near Lake Itasca. It affords facilities for the transport of logs by means of booms above Minneapolis, and is navigable below St Paul; being half a mile broad where it reaches the border of the state at Hastings. At the Falls of St Anthony, St Cloud, Little Falls and other places, it provides ample water-power for manufacturing purposes. Its two principal tributaries are the St Croix and the Minnesota. The first, after having for about 135 m. (about 50 being navigable) formed the boundary between Wisconsin and Minnesota, enters the Mississippi at Hastings; the second, rising in Big Stone Lake on the western border, but 1 m. from Lake Traverse, the source of the Red River, enters the Mississippi from the south-west between St Paul and Minneapolis after a course of about 450 m., about 240 of which are navigable at high water. Both furnish valuable water-power, which is true also of the Cannon and Zumbro rivers flowing into the Mississippi below Hastings. The Red River, which forms the western boundary of the state for more than half its distance, has its source in Lake Traverse. Its most important branch is the Red Lake River, and both are navigable for vessels of light draught at high water. In the south the western fork of the Des Moines River, flowing for 125 m. through the state, is navigable for 20 m. Glacial action determined the direction and character of the rivers, made numerous swamps, and, by scouring out rock basins, damming rivers and leaving morainal hollows, determined the character and formation of the lakes, of which Minnesota has upwards of 10,000, a number probably exceeding that of any other state in the Union. The general characteristics of the lakes in the north differ from those of the south, the former being generally deep, with ragged rocky shores formed by glacial scouring which caused rock basins, the latter being mostly shallow. The most interesting feature of the glacial epoch is the extinct Lake Agassiz, which the receding ice of the later glacial period left in the Red River Valley of Minnesota, North Dakota and Manitoba. This lake drained southward into the Gulf of Mexico via the Minnesota and Mississippi rivers, until the ice sheet which had prevented its natural drainage to the north had melted sufficiently to allow it to be drained off into Hudson Bay by way of the Nelson River. The remarkably level character of the Red River district is due to horizontal deposits in the bottom of this lake, which have been little dissected by river erosion. The largest of the present lakes, Red Lake, in Beltrami county, has an area of 342 sq. m. Other large lakes are Mille Lacs (198 sq. m.) in Mille Lacs and Aitkin counties; Leech Lake (184 sq. m.) in Cass county; Lake Winnibigashish (82 sq. m.) in Itasca county; and Vermilion Lake (66 sq. m.) in St Louis county. On the northern boundary are the Lake of the Woods (612 sq. m.) and Rainy Lake (148 sq. m.), draining northwards into Hudson Bay. The beautiful "Park Region," centring in Ottertail county, contains several thousand lakes. Several large lakes such as Pepin, Traverse and Big Stone are river expansions. The state supports three parks—Itasca state park (22,000 acres, established in 1891), about the sources of the Mississippi, in Clearwater, Becker and Hubbard counties; the St Croix (established in 1895), in Chicago county, across the St Croix from the Wisconsin state park of the same name, and including the beautiful Dalles of the St Croix; and the Minneopa state park (established in 1905), containing Minneopa Falls, near Mankato.

---

[1] Rudolf II., count of Neuenburg (d. 1196), or, according to some, a nephew of his who died in 1257.

[2] In addition the state contains approximately 2514 sq. m. of Lake Superior.

Flora and Fauna.—The flora and fauna are similar to those of the other states of the same latitude. The rapid settling of the state drove its native fauna, which comprised buffalo, deer, moose, bear, lynx and wolves, in great numbers into the northern sections, westward into Dakota, or across the Canadian border. Deer and moose are still found in the state. The preservation of game is now enforced by stringent game laws, administered by an efficient state Game and Fish Commission. The fisheries, which are of great value, are carefully supervised and systematically replenished from the State Fish Hatchery at St Paul, and the Federal Fish Hatchery maintained at Duluth, in which particular attention is devoted to the fish of Lake Superior. Minnesota ranked third among the states of the Union in 1900 in the production of lumber, but in 1905 was fifth, the supply having diminished and the industry having been developed in the states of Washington and Louisiana. The danger of loss from forest fires, such as that of 1894, emphasized the necessity of forest preservation, and resulted (1895) in the creation of a special state department with a forest commissioner and five wardens with power to enforce upon corporations and individuals a strict observance of the forestry laws, the good effects of the law being evidenced by the fact that the fire losses in forest lands for the first twelve years of its operation averaged only $31,000 a year. Furthermore, in order to encourage the growth and preservation of the forests, and to create systematically forest reserves, the legislature established in 1899 a State Forestry Board. There are two national forest reserves, with an aggregate area of 1882 sq. m.

Climate.—Minnesota has the characteristic climate of the North Central group of states, with a low mean annual temperature, a notably rarefied atmosphere that results in an almost complete absence of damp foggy weather, and an unusual dryness which during the rather long winters considerably neutralizes the excessive cold. The cold increases not only from south to north, but to some extent from east to west. The mean annual temperature, according to the reports of the U.S. Weather Bureau, varies from 45° F. at St Paul and points in the south of the state to 37° F., at points in the north-east and as far south-west as Moorhead, Clay county. In the south the season is usually without killing frost from early in May to late in September, but in the north it is not uncommon late in May or early in September. The amount of rain decreases from east to west, the mean annual rainfall being 32·7 in. at Grand Meadow in the south-east and 33·3 in. at Mount Iron in the north-east, but less than 25 in. at several points of observation in the western half of the state. In all sections about as much, or even more, rain falls in summer as in both autumn and winter, and the summer rains, together with the long summer days, are very favourable to a rapid growth and early maturity of crops. Nearly the whole state is usually covered with snow during the greater part of winter, and the mean annual fall of snow varies from about 52 in. at points in the north-east to less than 25 in. in the south-west. In most localities the prevailing winds are north-west in winter and southerly in summer, but at Duluth, on the shore of Lake Superior, they are south-west during November, December and January and north-east during all other months.

Soil and Minerals.—The surface drifts of the greater part of the state, which are almost wholly of glacial origin, have provided Minnesota with a remarkably fertile soil. It consists largely of a dark brown or black sandy loam, finely comminuted, the richness of which in organic matter and mineral salts induces rapidity of growth, and the strength and durability of which render it capable of a long succession of crops. This soil prevails throughout the southern counties and the Minnesota and Red River valleys, in which sections cereal crops predominate. Toward the east central part of the state there is a somewhat less fertile sandy soil, which is devoted more largely to potatoes and similar crops. The non-arable north-east portion of the state is covered with a coarse granite drift. Underneath the surface are beds of sand, gravel and clays, the last affording material for the manufacture of brick, tiles and pottery. The rock formations of the state furnish building stones of great value.

Minnesota ranked first among the states in 1902 in the production of iron ore. Although the iron ranges in the north-east had been explored about 1860 and were known to contain a great wealth of ore, it was not until 1884 that mining was actually begun on the Vermilion Range. Since that date the development of iron mining in Minnesota has been remarkable, and the increase both in volume and value of the output has been practically uninterrupted. Eight years later (1892) the much richer Mesabi Range, the most productive iron range in the world, was opened up; it soon surpassed the Vermilion in its output, and by 1902 the product was nearly ten times greater. The ore, which in many places is found in an almost pure state, is at or near the surface and the process of mining is one of great simplicity and ease. The quality of ore in the two ranges differs somewhat, that mined from the Vermilion Range being a hard specular or red haematite, while that taken from the Mesabi Range, largely red haematite, is much softer and in many localities quite finely comminuted.

Agriculture.—The principal industry of Minnesota is agriculture. Large areas of swamp lands in the central and north central parts of the state once counted non-arable have been drained and reclaimed. There were in 1900 154,659 farms aggregating 26,248,498 acres, of which 70·3% was improved land; the total value of farm property was $788,684,642, an increase in value of $373,983,016, or more than 90%, for the decade 1890–1900. The value of domestic animals on farms and ranges was $86,620,643. The total value of farm products for the year 1899 (census of 1900) was $161,217,304. Geographically the wheat-raising area extends across the entire south of the state—the Minnesota Valley and the Red River Valley—the rich glacial loam of which renders it one of the most productive wheat regions in the world. Other important crops in the order of their value are oats, hay and forage, Indian corn, barley, flax-seed, potatoes, rye, grass seeds, wild grass, clover, beans, peas, and miscellaneous vegetables and orchard products. Both fruit-raising and dairying interests are centred principally in the southern half of the state.

Manufactures and Commerce.—The extraordinary numbers of utilizable water-powers, the unusual transport facilities affording ample means of reaching the great markets, and finally the proximity to the raw materials of manufacture, have made Minnesota of great importance as a manufacturing state. The federal census showed for the decades 1880–1890 and 1890–1900 an increase in the number of manufacturing establishments from 3493 in 1880 to 7505 in 1890, and 11,114 in 1900. During the same period the capital invested increased from $31,004,811 in 1880 to $127,686,618 in 1890 and $165,832,246 in 1900, and the value of the manufactured products increased from $76,065,198 in 1880 to $192,033,478 in 1890 and $262,655,881 in 1900. The wonderful development of Minnesota as a flour-producing state began with the introduction of improved roller processes after 1870. Minneapolis is the chief flour-making centre of the world, and the cities at the "Head of the Lakes" (Duluth, Minnesota, and Superior, Wisconsin, considered industrially as one place) constitute the second largest centre. The towns of the Red River Valley, which are nearer to the great wheat belt, give promise of developing into great flouring cities. Next to flour, lumber and timber products rank in importance. Other manufactures of importance are butter, cheese and condensed milk, packed meats and other slaughter-house products, steam railway cars, foundry and machine-shop products, linseed oil, malt liquors, planing-mill products, sash, doors and blinds, boots and shoes, and agricultural implements. As compared with other states of the Union Minnesota ranked third in 1900 and fifth in 1905 in lumber; sixth in 1900 and fifth in 1905 in cheese, butter and condensed milk; eighth in 1900 and in 1905 in agricultural implements; and fourteenth in 1900 and eighth in 1905 in planing-mill products.

For an inland state Minnesota is exceptionally well situated to play a chief part in the commercial life of the country, and various causes combine to make it important in respect to its interstate and foreign trade. It is the natural terminal of three great northern transcontinental railway lines—the Northern Pacific, the Great Northern, and the Chicago, Milwaukee & Puget Sound (the extension of the Chicago, Milwaukee & St Paul system); and the Chicago, Burlington & Quincy and the connecting lines of the Canadian Pacific form lines of communication with the middle Northwest and the Pacific provinces of Canada. Seven navigable rivers within or on the borders of the state—the Red River of the north, the Red Lake River, Rainy River, the Minnesota, the Mississippi, the St Croix and the St Louis[1]—give facilities for transport by water that exert an important competing influence on freight charges; and at the "Head of the Lakes" (Duluth-Superior) many lines of steamships on the Great Lakes, providing direct or indirect connexion with the Eastern and Southern states, make that port in respect to tonnage the first in the United States. This combination of natural and artificial highways of commerce derives an additional importance from the character of the regions thus provided with transport facilities, which renders its cities the principal distributing centres both for the entire Northwest for coal shipped via the Great Lakes, and also for the eastern and middle Western states for the great staples, wheat and lumber, derived either from Minnesota itself or by means of its great transcontinental railways from the neighbouring Northwestern states and Canadian provinces. Iron shipments from the Mesabi and Vermilion ranges, cereals from the Northwest, fruits and vegetables from the Pacific coast, and Oriental products obtained via the great northern railways, are also elements of great importance in the state's commerce. There were on the 31st of December 1908 8438·73 m. of railway within the state. St Paul and Duluth are ports of entry.

Population.—The population of Minnesota at the first Federal census (1860) after its admission into the Union was 172,023, and by the succeeding Federal enumerations it was: (1870), 439,706; (1880), 780,773; (1890), 1,301,826, excluding Indians (10,096); (1900), 1,751,394; (1910) 2,075,708.[2] Of the total population in 1900, 932,490, or 53·2 %, were males, and 818,904, or 46·8 %, females; 1,246,076 were native-born; 505,318, or 28·9 %, were foreign-born, and 1,312,019 were of foreign parentage (*i.e.* having either one or both parents foreign-born). Of the 14,358 coloured inhabitants, 4959 were negroes and 9182 Indians, 8457 of whom lived on reservations. The urban population (*i.e.* inhabitants of cities of 8000 or over) was 26·8 % of the total population, as compared with 28·2 % in 1890. By the state census of 1905 the population of the principal cities was as follows: Minneapolis, 261,954; St Paul, 197,023; Duluth, 64,942; Winona, 20,334; Stillwater, 12,435; and Mankato, 10,996; by the same census four other cities, all in the mining region in the north-east, had passed the 5000 limit, viz. Hibbing, 6566; Cloquet, 6117; Virginia, 5056; and Eveleth, 5332. The density of population increased from 16·5 per sq. m. in 1890 to 22·1 in 1900. The largest religious denomination in the state in 1906 was the Roman Catholic, with 378,288 communicants out of a total of 834,442 members of all religious denominations; there were 267,322 Lutherans, 47,637 Methodists, 27,569 Presbyterians, 24,309 Baptists, 22,264 Congregationalists, and 18,763 Protestant Episcopalians.

Government.—The state is governed under the constitution adopted on the 13th of October 1857 and frequently amended. By an amendment of 1898 an amendment may be suggested by a majority of both houses of the legislature and comes into effect if approved by a majority of all electors voting at the general election at which the amendment is voted upon; if two or more amendments are submitted at the same election voters shall vote for or against each amendment separately. For the revision of the constitution it is necessary that two-thirds of the members elected to each house of the legislature vote for the call of a constitutional convention, that a majority of all electors voting at the next general election approve the call for the convention, and that the convention consist of as many members as the house of representatives, who shall be chosen in the same manner, and shall meet within three months after the general

---

[1] At International Falls on Rainy River and at Duluth on the St Louis immense water-power is utilized for manufacturing.

[2] By the state census of 1905 the total population was 1,979,912 (1,060,412 males and 909,275 females—excluding Indians from the sex classification), of whom 537,041 were foreign-born, 10,929 were Indians, 5113 were negroes, 171 were Chinese, and 50 were Japanese.

election at which it is voted. The executive department consists of a governor, lieutenant-governor, secretary of state, treasurer and attorney-general, elected biennially in November of the even-numbered years, and an auditor elected at the same time every four years. The veto power of the governor (since 1876) extends to separate sections of appropriation bills. The judicial department comprises a supreme court consisting of a chief justice and (since 1881) four associate justices elected for terms of six years, and lower courts consisting of district courts with original jurisdiction in civil cases in law and equity, and in criminal cases upon indictments by grand juries; justices' courts, in which the amount in litigation cannot exceed $100, or the punishment cannot exceed three months' imprisonment or a fine of $100; and of municipal and probate courts with the usual jurisdictions. The legislative department consists of a senate of sixty-three members elected for four years, and a house of representatives of one hundred and nineteen members, elected for two years, the remuneration being mileage and $500 a year. The reapportionment of congressional, senatorial and representative districts is made in the first legislative session after the state census, which has been taken in every tenth year since 1865. The legislature meets biennially in odd-numbered years, the session being limited to ninety days by a constitutional amendment of 1888. A majority of all the members elected to each house is required for the passage of a bill, and a two-thirds majority is necessary to pass a bill over the governor's veto. All bills for raising revenue must originate in the House of Representatives, but the senate may propose and concur with amendments as on other bills. Expenditures from the fund known as "The Internal Improvement Land Fund," derived from the sale of state lands, can be made only after the enactment for that purpose has been approved by the voters of the state; in 1881 the legislature, and in 1884 the popular vote, pledged the proceeds of this fund to the payment of Minnesota state railway adjustment bonds. Taxation must be uniform only within classes of property prescribed by the legislature. An Australian ballot law was enacted in 1891; the qualifications for electors (adopted in 1896) require that the voter be at least twenty-one years old, that he shall have been a full citizen of the United States for three months prior to the election, and shall have lived in the state six months and in the election district thirty days. Women (since 1898) may vote for school officers and members of library boards, and are eligible for election to any office pertaining to the management of schools or libraries. A constitutional amendment in regard to local government adopted in 1898 provides that any city or village, by a four-sevenths vote of its electors, may adopt a charter drawn by a commission (appointed by the local district judges) and proposed by such commission within six months of its appointment.

An amendment to the constitution adopted in November 1888 declares that any combination or pool to affect the markets for food products is a "criminal conspiracy, and shall be punished in such manner as the legislature may provide."

A homestead which is owned and occupied by a debtor as his dwelling place is exempt from seizure or sale for debts other than taxes, those secured by a mortgage on it, or those incurred for its improvement or repair, or for services performed by labourers or servants. But a homestead so exempted may not be larger than one-fourth of an acre if it is in an incorporated place having a population of 5000 or more, than half an acre if it is in an incorporated place having a population of less than 5000, or than eighty acres if it is outside an incorporated place. In case the owner is married the homestead cannot be sold or mortgaged, except for an unpaid portion of the purchase money, without the joinder of husband and wife, and if the owner dies leaving a spouse or minor children, the homestead with its exemptions descends to the surviving member or members of the family. If the owner is a husband and he deserts his family, the wife and minor children may retain the homestead. Under the laws of the state the legal existence and legal personality of a woman are not affected by marriage, and the property rights of a husband and wife are nearly equal. A husband may, however, convey his real estate, other than a homestead, by his separate deed, whereas a wife's deed for her real estate is void without the joinder of her husband. If either husband or wife dies intestate and there are no descendants the whole of the estate passes to the survivor; if there are descendants the surviving spouse has the use of the homestead for the remainder of his or her life, an absolute title to one-third of the other real estate of the deceased, and to personal property limited to $1000 besides wearing apparel. The grounds for an absolute divorce in Minnesota are adultery, impotence, cruel and inhuman treatment, sentence to state prison or state reformatory subsequent to the marriage, desertion or habitual drunkenness for one year next preceding the application for a divorce. Before applying for an absolute divorce the plaintiff must have resided in the state for the year next preceding, unless the cause of action is adultery committed while the plaintiff was a resident of the state. A wife may at any time sue for a limited divorce from her husband on the ground of cruel and inhuman treatment, of such conduct as to render life with him unsafe and improper, or of abandonment and refusal or neglect to provide for her, if both parties are inhabitants of the state or their marriage took place in the state. A law of 1909 provides for a women's and children's department in the state bureau of labour.

The sale of intoxicating liquors is for the most part regulated by licences, but the granting of licences may be prohibited within any town or incorporated village by its legal voters, and the question must be submitted to popular vote upon the request of ten legal voters.

Penal and Charitable Institutions.—The charitable and correctional institutions of Minnesota have been since 1901 under the supervision of a State Board of Control consisting of three paid members appointed by the governor and serving for terms of six years; this board supplanted an unpaid Board of Corrections and Charities established in 1883, and the boards of managers of separate institutions (except the schools for the deaf and the blind at Faribault, and the state public school at Owatonna) and of groups of institutions were abolished. The state institutions consist of state hospitals for the insane at St Peter (1866), at Rochester (1877), established originally as a state inebriate asylum under a law taxing liquor dealers for that purpose, which was subsequently held to be unconstitutional, at Fergus Falls (1887), at Anoka (1900) and at Hastings (1900); the state institute for defectives at Faribault, consisting of the schools for the deaf (1863), blind (1874) and feeble-minded (1879); the state public school for dependent and neglected children at Owatonna (1886); a sanatorium for consumptives at Walker; a hospital for indigent, crippled or deformed children (1907) at St Paul; the state training school for boys near Red Wing; a similar industrial school for girls (established separately in 1907) at Sauk Center; the state reformatory at St Cloud (1887), intermediate between the training school and the state prison, for first offenders between the ages of sixteen and thirty years, in which indeterminate sentences and a parole system are in operation; the state prison at Stillwater (1851), in which there is a parole system and a graded system of diminution of sentence for good conduct, and in which, up to 1895, prisoners were leased under contract (especially to the Minnesota Thresher Company), and since 1895 have been employed in the manufacture of shoes and of binding twine, and in providing for the needs of the prison population; and the state soldiers' home occupying fifty-one acres adjoining Minnehaha Park in Minneapolis. By an act of 1907 the Board of Control was empowered to establish a hospital for inebriates.

Education.—The state supports a highly efficient public school system, organized through all the grades from the primary district and rural schools to the state university. At the head of the system stands the state superintendent of public instruction, appointed by the governor; there are also county superintendents; and a state high school board, consisting of the governor, state superintendent and the president of the state university, has general supervision of the schools and apportions the state aid. The schools are supported by a state tax, and by the proceeds of a permanent school fund amounting (in 1908) to $19,709,383; in the same year the total value of all public school property was $28,297,420, with an aggregate debt of $6,329,794, and $13,463,211 was spent for public educational purposes. There are state normal schools at Winona (1860), Mankato (1868), St Cloud (1869), Moorhead (1888) and Duluth (1902). The university of Minnesota at Minneapolis was projected by the Territorial Legislature of 1851. Some ground was purchased for its campus in 1854, but it was actually founded by an act of 1864, amended in 1866, 1868 and 1872. It is governed by a board of twelve regents, of whom the president of the university, the governor of the state and the state superintendent of public instruction are members *ex officio*, and the other nine, holding office for six years, are appointed by the governor with the advice and consent of the senate. The university is supported by a state tax of 0·23 mills per dollar on the taxed property of the state, by special appropriations from the state (for "deficiency," for School of Mines, and for salaries of teachers in the department of mines and engineering), by the interest on state bonds and land contracts purchased with the proceeds of Federal land grants under the Morrill Act of 1862, by Federal appropriations under the Morrill Act of 1890 and the Hatch Act, and by students' fees, &c.; the total of this income was estimated in 1906–1907 at $628,500. The Act of 1872 provided for five or more colleges or departments: a college of science, literature and the arts, which offers (for the degree of Bachelor of Arts) a four-years course, is entirely elective (except that a certain number of "long courses" must be selected) after the first year, and in which the only restriction is upon the range of subjects from which the student's choice may be made; a college of agriculture (including military tactics), which is now a "department," including a college and a school of agriculture, a short course for farmers, a dairy school, the Crookston school of agriculture, a main experiment station at St Anthony Park, between Minneapolis and St Paul, and sub-stations 1 m. north of Crookston and 2 m. east of Grand Rapids; a college of mechanic arts, now called the college of engineering and the mechanic arts, which offers four-year courses in civil, mechanical, electrical and municipal engineering, a four-year course in science and technology, leading to the degree of Bachelor of Science, and graduate work leading to the degree of Master of Science; the college of law, a three-years course, with evening classes and graduate courses; a college of medicine, which is now the college of medicine and surgery (1888), and the college of homoeopathic medicine and surgery (1889), each with four-year courses, and each (since 1903) with a course of six years partly in the college of science, literature and the arts, and partly in the medical college and leading to the degrees of Bachelor of Science and Doctor of Medicine. In addition to these departments provided for in the organic act, the university included in 1909 colleges of dentistry (three-year course), pharmacy (two-year and three-year courses), a school of mines (1891; four-year course, leading to the degree of Engineer of Mines or Metallurgical Engineer), a school of analytical and applied chemistry (four-year courses, leading to the degree of Bachelor in Science in Chemistry or in Chemical Engineering), a college of education (1906; three-year course, after two years of college work, leading to a Master's degree), a graduate school (with courses leading to the degrees of Master of Arts, of Science and of Laws, and of Doctor of Philosophy, of Science and of Civil Law), and a university summer school. The growth and development of the university have been almost entirely under the administration of Cyrus Northrop (b. 1834), who graduated at Yale College in 1857 and at Yale Law School in 1859, and was professor of rhetoric and English literature at Yale from 1863 until 1884, when he became president of the university of Minnesota. The university is one of the largest in the country. In 1907 there were twenty-three buildings valued at more than $1,475,000. The university library of 110,000 volumes is supplemented by the libraries of Minneapolis and St Paul. In 1908-1909 the faculty numbered about 325 and the total enrolment of students was 4421. Other higher educational institutions in Minnesota are Hamline University (Methodist Episcopal), with a college of liberal arts at St Paul, and a college of medicine at Minneapolis; Macalester College (Presbyterian) at St Paul; Augsburg Seminary (Lutheran) at Minneapolis; Carleton College (non-sectarian, founded in 1866) and St Olaf College (Lutheran, founded in 1874) at Northfield; Gustavus Adolphus College (Lutheran) at St Peter; Parker College (Free Baptist, 1888) at Winnebago City; St John's University (Roman Catholic) at Collegeville, Stearns county; and Albert Lea College for women (Presbyterian, founded 1884) at Albert Lea.

History.—The first European visitors to the territory now embraced in the state of Minnesota found it divided between two powerful Indian tribes, the Ojibways or Chippewas, who occupied the heavily wooded northern portion and the region along the Mississippi river, and the Sioux or Dakotas, who made their homes on the more open rolling country in the south and west and in the valley of the Minnesota. The first known white explorers were Radisson and Groseilliers, who spent the winter of 1658–1659 among the Sioux in the Mille Lacs region. At Sault Sainte Marie in 1671, before representatives of fourteen Indian nations, the Sieur de St Lusson read a proclamation asserting the French claim to all the territory in the region of the Great Lakes. Two years afterwards the upper course of the Mississippi was explored by Joliet and Marquette. In 1679 Daniel Greysolon, Sieur du Lhut (Duluth), as agent for a company of Canadian merchants which sought to establish trading posts on the Lakes, explored the country from the head of Lake Superior to Mille Lacs and planted the arms of Louis XIV. in a large Sioux village. In the following year the Franciscan friar Father Louis Hennepin, acting as an agent of the Sieur de la Salle, discovered and named the Falls of St Anthony; and in 1686 Nicholas Perrot, the commandant of the west, built Fort St Antoine on the east bank of Lake Pepin, in what is now Pepin county, Wisconsin, and in 1688 formally took possession of the region in the name of the French king. A few years later (1694) Le Sueur, who had as early as 1684 engaged in trade along the upper Mississippi, established a trading post on Isle Pelée (Prairie Island) in the Mississippi between Hastings and Red Wing, and in 1700 he built Fort L'Huillier at the confluence of the Blue Earth and the Le Sueur rivers. In 1762 the Sieur de la Perrière, acting as an agent of the French government, established on the west bank of Lake Pepin a fortified post (Fort Beauharnois), which was to be a headquarters for missionaries, a trading post and a starting-point for expeditions in search of the "western sea." But none of the French posts was permanent, and in 1763 French rule came to an end, the Treaty of November (1762) and the Treaty of Versailles (1763) transferring respectively the western portion of the state to Spain and that part east of the Mississippi river to Great Britain. In 1766 the region was visited by the Connecticut traveller Jonathan Carver (1732–1780). Great Britain surrendered its title to the eastern portion by the Treaty of Paris (1783), and after the surrender of Virginia's colourable title had been accepted by Congress in 1784, this eastern part was made a part of the Northwest Territory by the ordinance of 1787, although the British held possession and did some trading there until 1796. The western part remained under Spanish control until 1803, when it, too, after being retransferred to France, became a part of the United States with the rest of the Louisiana Purchase. In 1805–1806, at the instance of President Thomas Jefferson, Lieut. Zebulon M. Pike led an exploring expedition as far north as Leech Lake and took formal possession of the Minnesota region for the United States. He obtained from the Sioux for military reservations one tract 9 m. square at the mouth of the St Croix River and another containing about 100,000 acres at the confluence of the Minnesota and Mississippi rivers. On the latter tract a military post was established by Lieut.-Colonel Henry Leavenworth (1783–1834) in 1819, and in the following year the construction was begun of a fort at first named Fort St Anthony but renamed Fort Snelling in 1824 (two years after its completion) in honour of its builder and commander Colonel Josiah Snelling (1782–1829). In 1819 Michigan Territory was extended westward to the Mississippi river, and in 1820 General Lewis Cass, its governor, conducted an exploring expedition in search of the source of the Mississippi, which he was satisfied was in the body of water named Lake Cass in his honour. Further search for the true source of the Mississippi was made in 1823 by Giacomo Constantio Beltrami (1779–1855), an Italian traveller and political refugee, and in 1832 by Henry Rowe Schoolcraft, who had accompanied Cass's expedition and traced the Mississippi from Lake Cass to Lake Itasca. In 1823 extensive explorations of the Minnesota and Red River valleys were conducted by Major Stephen Harriman Long (1784–1864), and subsequently (1834–1836) knowledge of the region was extended by the investigations of the artist George Catlin (1796–1872), the topographer George William Featherstonhaugh (1780–1866), and the geologist Jean Nicholas Nicollett (1786–1843). Meanwhile, the country was slowly being settled. In 1823 the first river steamboat reached St Paul; the Mississippi was soon afterwards opened to continuous if irregular navigation; and in 1826 a party of refugees from Lord Selkirk's colony on the Red River settled near Fort Snelling. On the erection of Wisconsin Territory in 1836 the whole of Minnesota, which then extended westward to the Missouri river, was incorporated with it, but on the erection of Iowa Territory in 1838 Minnesota was divided and the part west of the Mississippi became a part of Iowa Territory. In 1837, by two important treaties, the one (July 29) between the Chippewas and Governor Henry Dodge of Wisconsin at St Peters, and the other (Sept. 29) between some Sioux chiefs and Joel R. Poinsett at Washington, the Indian titles to all lands east of the Mississippi were practically extinguished. The first county, St Croix, was established in 1839, and in the succeeding years thriving settlements were established at St Paul and Stillwater. The admission of Wisconsin as a state in 1848 left that part of the former territory west of the St Croix and north of the Mississippi rivers, which was not included in the new state, practically without a government. On the 26th of August a convention met at Stillwater, where measures were taken for the formation of a separate territorial government, and Henry Hastings Sibley (1811–1891) was sent to Congress as a delegate of "Wisconsin Territory." Upon his admission to a seat the curious situation was presented of representatives of the state and of the territory of Wisconsin sitting in the same body. This situation did not last long, however, for on the 3rd of March 1849 the bill organizing the territory of Minnesota was passed, and on the 19th President Zachary Taylor appointed Alexander Ramsey of Pennsylvania the first territorial governor. The territorial boundaries extended to the Missouri river, including a greater part of the present North and South Dakota. The first territorial legislature met at St Paul on the 3rd of September following. By the Federal census of 1850 the territory had a population of 6077, most of whom lived east of the Mississippi, or along the Red river in the extreme north-west. Two treaties negotiated with the Sioux by Luke Lea, commissioner, and Governor Alexander Ramsey in 1851 opened to settlement the greater part of the land within the territory west of the Mississippi, and such an unparalleled rush to the new lands took place that a census taken in 1857 showed a population of 150,037. In July 1857 a convention chosen to form a state constitution was found on assembling to be so evenly divided between the Republican and Democratic parties that organization was impossible, and the members proceeded to their work in two separate bodies. By means of conference committees, however, identical constitutions were formed, which in the following October were adopted by an almost unanimous popular vote. The state was admitted to the Union with its present boundaries on the 12th of May 1858, and the federal census of 1860 showed that the population had increased to 172,023, despite the fact that the financial panic of 1857 had severely checked the state's growth. Minnesota furnished more than 25,000 troops for the Federal armies during the Civil War. But even more pressing than the call of the nation was the need of defending her own homes against the uprisings of the Indians within her borders. The settlements bordering on the Indian reservations had experienced more or less trouble with the Sioux for several years, the most serious outbreak having occurred in March 1857, when Ink-pa-du-ta led his band to massacre the settlers at Spirit Lake. The absence of a large proportion of the able-bodied young settlers in the northern armies was taken advantage of by the Indians, and in the summer of 1862 there was delay in paying them their yearly allowance. Suddenly towards the end of August, as if by previous understanding (although nothing of the sort was ever proved), small bands of Sioux scattered along the frontier for 200 m. and began a systematic massacre of the white settlers. Beginning with the first outbreak at Acton, Meeker county (Aug. 17), the attacks continued with increasing fury (nearly 1000 whites losing their lives) until the 23rd of September, when hastily-raised volunteer forces under Colonel H. H. Sibley decisively defeated Little Crow, the principal leader of the Kaposia band, at Wood Lake. Three days later more than 2000 of the Indians were surrounded and captured, Little Crow with a few of his companions alone escaping beyond the Missouri. A military commission tried 425 of the captives for murder and rape, of whom 321 were found guilty and 303 were condemned to death. Of these 38 were hanged at Mankato on the 26th of December 1862. Little Crow and his followers kept up desultory raids from the Dakota country, during one of which in July 1863 he lost his life. Expeditions of Sibley in 1863, and General Alfred Sully (1821–1879) in 1864, eventually drove the hostile Indians beyond the Missouri and terminated the war, which in two years had cost upwards of a thousand lives of settlers and volunteers. The opening of the Chippewa lands in the north-west and the coming of peace marked the beginning of a new period of rapid growth, the Federal census of 1870 showing a population of 439,706, or a gain of 75·8 % in five years. During the same half-decade railway construction, which had begun with the opening of the railway between St Paul and Minneapolis in 1862, reached a total of more than 1000 m. For a period of five years after the financial panic of 1873 the growth was comparatively slow, but in the succeeding two years the recuperation was rapid. During the decade, 1880–1890, more than 2300 m. of railway were completed and put in operation. In September 1894 disastrous forest fires, starting in the neighbourhood of Hinckley in Pine county, destroyed that village and several neighbouring towns, causing the death of 418 people, rendering 2200 others homeless, and devastating about 350 sq. m. of forest land, entailing a loss of more than $1,000,000. The state furnished four regiments (a total of 5313 officers and men) to the volunteer army during the Spanish-American War (1898), the service of the 13th Regiment for more than a year in the Philippines being particularly notable. In October 1898 there was an uprising of the Pillager band of Chippewa Indians at Leech Lake, which was quelled by the prompt action of Federal troops. Since the first state election, which was carried by the Democratic party, the state has been generally strongly Republican in politics; but the Republican candidate for governor was defeated in 1898 by a "fusion" of Democrats and Populists, and in 1904, 1906 and 1908 a Democratic governor, John Albert Johnson, was elected, very largely because of his personal popularity.

GOVERNORS OF MINNESOTA.

Territorial.		
Alexander Ramsey	Whig	1849–1853
Willis Arnold Gorman	Democrat	1853–1857
Samuel Medary	,,	1857–1858
State.		
Henry Hastings Sibley	Democrat	1858–1860
Alexander Ramsey	Republican	1860–1863
Henry A. Swift	,,	1863–1864
Stephen Miller	,,	1864–1866
William Rogerson Marshall	,,	1866–1870
Horace Austin	,,	1870–1874
Cushman Kellogg Davis	,,	1874–1876
John Sargent Pillsbury	,,	1876–1882
Lucius Fairchild Hubbard	,,	1882–1887
Andrew Ryan McGill	,,	1887–1889
William Rush Merriam	,,	1889–1893
Knute Nelson	,,	1893–1895
David Marston Clough	,,	1895–1899
John Lind	Democrat-Populist	1899–1901
Samuel R. Van Sant	Republican	1901–1905
John Albert Johnson	Democrat (died in office)	1905–1909
Adolph Olson Eberhart	Republican	1909–

BIBLIOGRAPHY.—There is a well-arranged *Bibliography of Minnesota* by John Fletcher Williams in the *Collections* of the Minnesota Historical Society, vol. iii. (St Paul, 1880). Consult also *Materials for the Future History of Minnesota*, published by the State Historical Society (St Paul, 1856), and Isaac S. Bradley's bibliography of North-western institutional history in the *Proceedings* of the Wisconsin State Historical Society (Madison, Wis., 1896). Of the many interesting and valuable narratives and descriptions of Minnesota in the early days, those especially worthy of mention are Beltrami's *La Découverte des sources des Mississippi et de la Rivière Sanglante* (New Orleans, 1824) and the same author's *A Pilgrimage in Europe and America, leading to the Discovery of the Sources of the Mississippi and Bloody Rivers* (2 vols., London, 1828); William H. Keating, *Narrative of an Expedition to the Sources of the St Peter* (Minnesota) *River, Lake Winnepeek, Lake of the Woods, &c. . . . in 1823* (2 vols., London, 1825), an account of the explorations of Major Long; Henry R. Schoolcraft, *Narrative of an Expedition through the Upper Mississippi to Itasca Lake . . . in 1832* (New York, 1834); G. W. Featherstonhaugh, *A Canoe Voyage up the Minnay Sotor* (2 vols., London, 1847); Laurence Oliphant, *Minnesota and the Far West* (Edinburgh, 1855); and Frederika Bremer, *The Homes of the New World: Impressions of America* (2 vols., New York, 1864). For the territorial period consult also E. S. Seymour, *Sketches of Minnesota, the New England of the West* (New York, 1850); J. Wesley Bond, *Minnesota and its Resources* (New York, 1853); C. A. Andrews, *Minnesota and Dacotah* (Washington, 1857); and C. E. Flandreau, *The History of Minnesota and Tales of the Frontier* (St Paul, 1901). The *Collections* of the Minnesota State Historical Society contain much valuable material on the history of the state, notably E. D. Neill's "French Voyageurs to Minnesota during the Seventeenth Century" (1872); E. D. Neill's "Early French Forts" (1889); T. F. Moran's "How Minnesota became a State" (1898); H. L. Moss's "Last Days of Wisconsin Territory and Early Days of Minnesota Territory" (1898); C. E. Flandreau's "Reminiscences of Minnesota during the Territorial Period" (1901); C. D. Gilfillan's "Early Political History of Minnesota" (1901); and James H. Baker's *Lives of the Governors of Minnesota* (1908). For the Sioux uprising consult Isaac V. D. Heard, *History of the Sioux War and the Massacres of 1862 and 1863* (New York, 1864); Charles S. Bryant and Abel B. Murch, *A History of the Great Massacre by the Sioux Indians in Minnesota* (Cincinnati, 1864); and S. R. Foot, "The Sioux Indian War," in *Iowa Historical Record*, vols. x. and xi. (1894–1895). Consult also *Minnesota in the Civil and Indian Wars, 1861–1865* (2 vols., St Paul, 1890–1893). The best general account of the state's history is W. W. Folwell's *Minnesota, the North Star State* (Boston, 1908), in the "American Commonwealth series"; E. D. Neill's *Concise History of Minnesota* (Minneapolis, 1887); and T. H. Kirk's *Illustrated History of Minnesota* (St Paul, 1887) may also be consulted. For an account of the administration consult Frank L. McVey, *The Government of Minnesota*

(New York, 1901); Sanford Niles, *History and Civil Government of Minnesota* (Chicago, 1897); and the *Legislative Manual*, published biennially by the state at St Paul.

MINNOW (*Leuciscus phoxinus*), the smallest British fish of the Cyprinoid family, readily distinguished by its very minute scales. The ordinary name is derived from the common Indo-European word for "little" (cf. Lat., *minor*), and "minnow" is popularly identified with any tiny fish; in America it is given to small forms of the *Gambusia* and *Notropis* genera, &c. The British minnow abounds in lakes, rivers and brooks, swimming in schools, and shifting its ground in search of food, in the shape of every kind of animal and vegetable substance. It ranges from Scandinavia to south Europe, and from Ireland to north-east Asia, attaining an elevation of nearly 8000 ft. in the Alps. Its size varies from between 2 and 3 in. to as much as 4 or 5 in. The minnow is commonly used by anglers for bait, and is useful in ponds as food for trout, perch or pike.

MINO DI GIOVANNI (1431–1484), called Da Fiesole, Italian sculptor, was born at Poppi in the Casentino. He had property at Fiesole. Vasari's account of him is very inaccurate. Mino was a friend and fellow-worker with Desiderio da Settignano and Matteo Civitale, all three being about the same age. Mino's sculpture is remarkable for its finish and delicacy of details, as well as for its spirituality and strong devotional feeling. Of Mino's earlier works, the finest are in the duomo of Fiesole, the altarpiece and tomb of Bishop Salutati, executed before 1466. In the Badia of Florence are an altarpiece and the tombs of Bernardo Giugni (1466) and the Margrave Hugo (1481), all sculptured in white marble, with life-sized recumbent effigies and attendant angels. The pulpit in Prato Cathedral, in which he collaborated with Antonio Rossellino, finished in 1473, is very delicately sculptured with bas-reliefs of great minuteness, but somewhat weakly designed. Soon after the completion of this work Mino went to Rome, where he executed the tomb of Pope Paul II. (now in the crypt of St Peter's), the tomb of Francesco Tornabuoni in S. Maria sopra Minerva, and a beautiful little marble tabernacle for the holy oils in S. Maria in Trastevere. There can be little doubt that he was also the sculptor of several monuments in S. Maria del Popolo, especially those of Bishop Gomiel and Archbishop Rocca (1482), and the marble reredos given by Pope Alexander VI. Some of Mino's portrait busts and profile bas-reliefs are preserved in the Bargello at Florence; they are full of life and expression, though without the extreme realism of Verrocchio and other sculptors of his time.

See Vasari, Milanesi's ed. (1878–1882); Perkins's *Italian Sculptors*, Winckelmann and D'Agincourt, *Storia della scultura* (1813); Hans Semper, *Architekten der Renaissance* (Dresden, 1880); Wilhelm Bode, *Die italienische Plastik* (Berlin, 1893).

MINOR, ROBERT CRANNELL (1839–1904), American artist, was born in New York city on the 30th of April 1839, and received his art training in Paris under Diaz, and in Antwerp under Joseph Van Luppen. His paintings are characteristic of the Barbizon school, and he was particularly happy in his sunset and twilight effects; but it was only within a few years of his death that he began to have a vogue among collectors. In 1897 he was elected a member of the National Academy of Design, New York. After 1900 he lived at Waterford, Connecticut, where he died on the 4th of August 1904.

MINOR (Lat. for smaller, lesser), a word used both as an adjective and as a substantive for that which is less than or inferior to another, and often correlatively opposed to that to which "major" is applied in the same connotation. Among the numerous special uses of the word the following may be mentioned: "Minor Friars," sometimes known as "Minorites," *i.e.* the name (fratres minores, lesser brothers) given by St Francis to the order he founded (see Franciscans); "minor canons" are clergymen attached to a cathedral or collegiate church who read and sing the daily service. In some cathedrals they are known as "vicars choral"; they are not members of the chapter. (For the distinction between holy and minor orders in Christian hierarchy see Orders.). The name "Minor Prophets" is used collectively of the twelve prophetical books of the Old Testament from Hosea to Malach inclusive. (For the distinction in music between major and minc intervals, and for other applications of the correlative term, se Music and Harmony.) In the categorical syllogism (*q.v.*) i logic, the minor term is that term which forms the subject of th conclusion, the minor premiss is that which contains the minc term. In law, a "minor" is a person under legal age (se Infant).

In mathematics, the "minor of a determinant" is the determinant formed by erasing an equal number of the rows an columns of the original determinant. If one column and row b erased there is formed the first minor; if two rows and columr the second minor, and so on. The minor axis of a central coni section is the shorter of the two principal axes; it may also b regarded as the line joining the two imaginary foci. In astronomy, the term minor planets is given to the members of th solar system which have their orbits between those of Mars an Jupiter (see Planets, Minor).

MINORCA (Menorca), the second in size of the group of Spanis islands in the Mediterranean Sea, known as the Balearic Island (*q.v.*), 27 m. E.N.E. of Majorca. Pop. (1900), 371,512; area 260 sq. m. The coast is deeply indented, especially on the north with numerous creeks and bays—that of Port Mahon (17,144 being one of the finest in the Mediterranean, if not the best c them all, according to the popular rhyme—

> "Junio, Julio, Agosto y puerto Mahon
> Los mejores puertos del Mediterraneo son"—

"June, July, August and Port Mahon are the best harbours c the Mediterranean" (see Port Mahon). The ports Addaya Fornelle, Ciudadela and Nitja may also be mentioned. Th surface of the island is uneven, flat in the south and rising irregularly towards the centre, where the mountain El Toro—probabl so called from the Arabic *tor*, a height, though the natives have legend of a *toro* or bull—has an altitude of 1207 ft. The climat is not so equable as that of Majorca, and the island is exposed i autumn and winter to the violence of the north winds. Its so is of very unequal quality; that of the higher districts being ligh fine, and fertile, and producing regular harvests without muc labour, while that of the plains is chalky, scanty, and unfit fo pasture or the plough. Some of the valleys have a good alluvia soil; and where the hills have been terraced they are cultivate to the summit. The wheat and barley raised in the island ar sometimes sufficient for home consumption; there is rarely surplus. The *Hedysarum coronarium*, or *zulla*, as it is calle by the Spaniards, is largely cultivated for fodder. Wine, oi potatoes, hemp and flax are produced in moderate quantitie fruit of all kinds, including melons, pomegranates, figs an almonds, is abundant. The caper plant is common throughou the island, growing on ruined walls. Horned cattle, sheep ar goats are reared, and small game abound. Stone of variou kinds is plentiful. In the district of Mercadal and in Mour Santa Agueda are found fine marbles and porphyries; lime ar slate are also abundant. Lead, copper and iron might be worke were it not for the scarcity of fuel. There are manufactures the wool, hemp and flax of the island; and formerly there was good deal of boat-building; but agriculture is the chief industr An excellent road, constructed in 1713–1715 by Brigadie General Richard Kane, to whose memory a monument wa erected at the first milestone, runs through the island fro south-east to north-west, and connects Port Mahon wi Ciudadela. Ciudadela (8611), which was the capital of th island till Port Mahon was raised to that position by th English, still possesses considerable remains of its form importance.

MINOS, a semi-legendary king of Crete, son of Zeus ar Europa. By his wife, Pasiphaë, he was the father of Ariadn Deucalion, Phaedra and others. He reigned over Crete and th islands of the Aegean three generations before the Trojan Wa He lived at Cnossus for periods of nine years, at the end of whi he retired into a sacred cave, where he received instruction fro Zeus in the legislation which he gave to the island. He was th author of the Cretan constitution and the founder of its nav supremacy (Herodotus iii. 122; Thucydides i. 4). In Attic tradition and on the Athenian stage Minos is a cruel tyrant, the heartless exactor of the tribute of Athenian youths to feed the Minotaur (*q.v.*). It seems possible that tribute children were actually exacted to take part in the gruesome shows of the Minoan bull-rings, of which we now have more than one illustration (see CRETE: *Archaeology*). To reconcile the contradictory aspects of his character, two kings of the name of Minos were assumed by later poets and mythologists. Since Phoenician intercourse was in later times supposed to have played an important part in the development of Crete, Minos is sometimes called a Phoenician. There is no doubt that there is a considerable historical element in the legend; recent discoveries in Crete (*q.v.*) prove the existence of a civilization such as the legends imply, and render it probable that not only Athens, but Mycenae itself, was once subject to the kings of Cnossus, of whom Minos was greatest. In view of the splendour and wide influence of Minoan Crete, the age generally known as "Mycenaean" has been given the name of "Minoan" by Dr Arthur Evans as more properly descriptive (see CRETE). Minos himself is said to have died at Camicus in Sicily, whither he had gone in pursuit of Daedalus, who had given Ariadne the clue by which she guided Theseus through the labyrinth. He was killed by the daughter of Cocalus, king of Agrigentum, who poured boiling water over him in the bath (Diod. Sic. iv. 79). Subsequently his remains were sent back to the Cretans, who placed them in a sarcophagus, on which was inscribed: "The tomb of Minos, the son of Zeus." The earlier legend knows Minos as a beneficent ruler, legislator, and suppressor of piracy (Thucydides i. 4). His constitution was said to have formed the basis of that of Lycurgus (Pausanias iii. 2, 4). In accordance with this, after his death he became judge of the shades in the under-world (*Odyssey*, ix. 568); later he was associated with Aeacus and Rhadamanthus.

The solar explanation of Minos as the sun-god has been thrown into the background by the recent discoveries. In any case a divine origin would naturally be claimed for him as a priest-king, and a divine atmosphere hangs about him. The name of his wife, Pasiphaë ("the all-shining"), is an epithet of the moon-goddess. The name Minos seems to be philologically the equivalent of Minyas, the royal ancestor of the Minyans of Orchomenus, and his daughter Ariadne ("the exceeding holy") is a double of the native nature-goddess. (See CRETE; *Archaeology*.)

On Cretan coins Minos is represented as bearded, wearing a diadem, curly-haired, haughty and dignified, like the traditional portraits of his reputed father, Zeus. On painted vases and sarcophagus bas-reliefs he frequently occurs with Aeacus and Rhadamanthus as judges of the under-world and in connexion with the Minotaur and Theseus.

MINOT, LAURENCE (fl. 1333–1352), English poet, the author of eleven battle-songs, first published by Joseph Ritson in 1795 as *Poems on Interesting Events in the reign of King Edward III.* They had been discovered by Thomas Tyrwhitt in a MS. (Cotton Galba, E. IX., British Museum) which bore on the fly-leaf the misleading inscription: "Chaucer, Exemplar emendate scriptum." It dates from the beginning of the 15th century. The authorship of Laurence Minot's eleven songs is fixed by the opening of the fifth: "Minot with mowth had menid to make," and in VII. 20, "Now Laurence Minot will begin." The poems were evidently written contemporaneously with the events they describe. The first celebrates the English triumph at Halidon Hill (1333), and the last the capture of Guines (1352). The writer is animated by an ardent personal admiration for Edward III. and a savage joy in the triumphs of the English over their enemies. The technical difficulty of his metres and the comparatively even quality of the work led to the inference that Minot had written other songs, but none have come to light. Nothing whatever is known of his life, but the minuteness of his information suggests that he accompanied Edward on some of his campaigns. Though his name proves him to have been of Norman birth, he writes vigorous and idiomatic English of the northern dialect with some admixture of midland forms. His poems are instinct with a fierce national feeling, which has been accepted as an index of the union of interests between the Norman and English elements arising out of common dangers and common successes.

There are excellent editions of Minot's poems by Wilhelm Scholle (*Quellen und Forschungen*, vol. lii., Strasburg, 1884), with notes on etymology and metre, and by Mr J. Hall (Clarendon Press, 2nd ed., 1897). Mr Hall is inclined to include as his work the "Hymn to Jesus Christ and the Virgin" (*Religious Pieces*, Early English Text Society, No. 26, p. 76), on the grounds of similarity of style and language. See also T. Wright, *Political Poems and Songs* (Rolls series, 1859).

MINOTAUR (Gr. Μινώταυρος, from Μίνως, and ταῦϝος, bull), in Greek mythology, a fabulous Cretan monster with the body of a man and the head of a bull. It was supposed to be the offspring of Pasiphaë, the wife of Minos, and a snow-white bull, sent to Minos by Poseidon for sacrifice. Minos, instead of sacrificing it, spared its life, and Poseidon, as a punishment, inspired Pasiphaë with an unnatural passion for it. The monster which was born was shut up in the Labyrinth (*q.v.*). Now it happened that Androgeus, son of Minos, had been killed by the Athenians, who were jealous of the victories he had won at the Panathenaic festival. To avenge the death of his son, Minos demanded that seven Athenian youths and seven maidens should be sent every ninth year to be devoured by the Minotaur. When the third sacrifice came round Theseus volunteered to go, and with the help of Ariadne (*q.v.*) slew the Minotaur (Plutarch, *Theseus*, 15–19; Diod. Sic. i. 16, iv. 61; Apollodorus iii. 1, 15). Some modern mythologists regard the Minotaur as a solar personification and a Greek adaptation of the Baal-Moloch of the Phoenicians. The slaying of the Minotaur by Theseus in that case indicates the abolition of such sacrifice by the advance of Greek civilization.

According to A. B. Cook, Minos and Minotaur are only different forms of the same personage, representing the sun-god Zeus of the Cretans, who represented the sun as a bull. He and J. G. Frazer both explain Pasiphaë's monstrous union as a sacred ceremony (ἱερὸς γάμος), at which the queen of Cnossus was wedded to a bull-formed god, just as the wife of the ἄρχων βασιλεύς in Athens was wedded to Dionysus. E. Pottier, who does not dispute the historical personality of Minos, in view of the story of Phalaris (*q.v.*) considers it probable that in Crete (where a bull-cult may have existed by the side of that of the double axe) victims were tortured by being shut up in the belly of a red-hot brazen bull. The story of Talos, the Cretan man of brass, who heated himself red-hot and clasped strangers in his embrace as soon as they landed on the island, is probably of similar origin. The contest between Theseus and the Minotaur was frequently represented in Greek art. A Cnossian didrachm exhibits on one side the labyrinth, on the other the Minotaur surrounded by a semicircle of small balls, probably intended for stars; it is to be noted that one of the monster's name was Asterius.

See A. Conze, *Theseus und Minotauros* (1878); L. Stephani, *Der Kampf zwischen Theseus und Minotauros* (1842), with plates and history of the legend; L. Preller, *Griechische Mythologie*; Helbig in Roscher's *Lexicon der Mythologie*; F. Durrbach in Daremberg and Saglio's *Dictionnaire des antiquités*; A. B. Cook in *Classical Review*, xvii. 410; J. G. Frazer, *Early History of the Kingship* (1905); E. Pottier in *La Revue de Paris* (Feb. 1902); the story is told in Kingsley's *Heroes*.

MINSK, a government of western Russia, bounded by the governments of Vilna, Vitebsk, Mogilev and Chernigov on the N. and E. and by Kiev, Volhynia and Grodno on the S. and W. It has an area of 35,283 sq. m. The surface is undulating and hilly in the north-west, where a narrow plateau and a range of hills (800–1000 ft.) of tertiary formation separate the basin of the Niemen, which flows into the Baltic, from that of the Dnieper, which sends its waters into the Black Sea. The remainder of the government is flat, 450 to 650 ft. above sea-level, and covered with sands and clays of the glacial and post-glacial periods. Two broad shallow depressions, drained by the Berezina and the Pripet, cross the government from north to south and from west to east; and these, as well as the triangular space between them, are occupied by immense marshes (often as much as 200 to 600 sq. m. each), ponds and small lakes, peat-bogs and moving sands, intermingled with dense forests. This country, and especially its south-western part, is usually known under the name of Polyesie ("The Woods"). Altogether, marshes and moors take up 22% and marshy forests no less than 40¼% of the entire area of the province. It is only in the north-west that the forests consist of full-grown trees; those which grow on the marshy ground are small, stunted pine, birch and aspen. The climate of the Polyesie is extremely unhealthy; malarias and an endemic disease of the hair (*plica Polonica*) are the plagues of these tracts. Communication is very difficult. The railway from Poland to Moscow has taken advantage of the plateau above mentioned; but still it has to cross the broad marshy depression of the Berezina. A successful attempt was made to drain the marshes of the Polyesie by a system of canals, and more than 4,500,000 acres have thus been rendered suitable for pasture and agriculture. Two tributaries of the Dnieper—the Berezina and the Pripet—both navigable, with numberless subtributaries, many also navigable, are the natural outlets for the marshes. The Dnieper flows along its south-eastern border for 160 m. and the Niemen on the north-western for 130 m. The affluents of the Baltic, the Dvina and the Vistula, are connected by canals with tributaries of the Dnieper. The estimated population in 1906 was 2,581,400. The peasants constitute 65% of the population, who are mostly White Russians (71%); there are also Poles (12%), Jews (16%), Little Russians and Great Russians. About 70,000 are considered to be Lithuanians; there are also 4500 Tatars and 2000 Germans.

The principal occupation of the inhabitants is agriculture, which is very unproductive in the lowlands; in the Polyesie the peasants rarely have pure bread to eat. Only 23·5 % of the area is under crops. Cattle-breeding is very imperfectly developed. Hunting and bee-keeping are sources of income in the Polyesie, and fishing gives occupation to about 20,000 persons. Gardening is carried on in some parts. The chief source of income for the inhabitants of the lowlands is the timber trade. Timber is floated down the rivers, and tar, pitch, various products of bark, potash, charcoal and timber-ware (wooden dishes, &c.) are manufactured in the villages to a great extent; and ship-building is carried on along the Dnieper, Pripet and Niemen. Shipping is also an important source of income. The industrial arts are almost entirely undeveloped, but there are several distilleries, flour-mills, saw-mills and tanneries, and woollen-stuffs, candles, tobacco, matches and sugar are manufactured. The great highway from Warsaw to Moscow crosses the government in the south, and its passage through the Berezina is protected by the first-class fortress of Bobruisk. The government is divided into nine districts, of which the chief towns and populations in 1897 are: Minsk, capital of the government (*q.v.*), Bobruisk (35,177), Igumeñ (4579), Mozyr (10,762), Novogrudok (7700), Pinsk (27,938), Ryechitsa (10,681) and Slutsk (14,180).

This region was originally inhabited by Slavs. That portion of it which was occupied by the Krivichi became part of the Polotsk principality, and so of White Russia; the other portion, occupied by the Dregovichi and Drevlyans, became part of Black Russia; whilst the south-western portion was occupied by Yatvyags or Lithuanians. During the 12th, 13th and 14th centuries it was divided among several principalities, which were successively incorporated with Lithuania, and later annexed to Poland. Russia took possession of this country in 1793. In 1812 it was invaded by the army of Napoleon I. Archaeological finds of great value, dating from the Neolithic and subsequent ages, have lately been made. (P.A.K.; J.T.Be.)

MINSK, a town of Russia, capital of the government of the same name, on the Svisloch, a tributary of the Berezina, at the intersection of the Moscow-Warsaw and Libau-Kharkov railways, 430 m. by rail W. from Moscow. It had, in 1897, 91,494 inhabitants, of whom one-third were Jews of the poorest class; the others were White Russians, Poles and Tatars. Amongst its public buildings is a cathedral, built in 1611. Minsk is the headquarters of the IVth Army Corps and the see of a bishop of the Orthodox Greek Church, and from 1798 to 1853 it was a see of the Roman Catholic Church. The manufactures are few and insignificant. Since the introduction of railways the commercial importance of the place, which formerly was slight, has begun to increase.

Minsk is mentioned in Russian annals in the 11th century under the name of Myen'sk, or Menesk. In 1066 and 1096 it was devastated, first by Izyazlav and afterwards by Vladimir, prince of Kiev. It changed rulers many times until the 13th century, when it became a Lithuanian fief. In the 15th century it was part of Poland, but as late as 1505 it was ravaged by Tatars, and in 1508 by Russians. In the 18th century it was taken several times by Swedes and Russians. Russia annexed it in 1793. Napoleon I. took it in 1812.

MINSTER, two towns of Kent, England.

1. Minster-in-Thanet, in the Isle of Thanet parliamentary division, lies on the southern slope of the isle, above the Minster marshes, in the low, flat valley of the river Stour, 4 m. west of Ramsgate, on the South-Eastern & Chatham railway. Pop. (1901), 2338. Its church, dedicated to St Mary, is cruciform, with a western tower, the nave a fine example of Norman work, the transepts and chancel a beautiful Early English addition. The carved choir-stalls are a notable feature. The church belonged to a nunnery, founded at the close of the 7th century. The abbey, a residence close to the church, incorporates portions of the ancient buildings. Fruit-growing is largely carried on in the neighbourhood.

2. Minster-in-Sheppey, in the north-eastern parliamentary division, lies in the Isle of Sheppey, near the north coast. Pop. (1901), 1306. It is served by the Sheppey light railway from Sheerness, 2 m. west. The village has in modern times become a seaside resort. It has a fine church, dedicated to St Mary and St Sexburga, originally attached to a convent of the 7th century, founded by Sexburga, widow of Erconberht, king of Kent. The building as it stands is only a portion of the conventual church founded in the early part of the 12th century by William de Corbeuil, archbishop of Canterbury; it retains also traces of pre-Norman work. It contains some interesting early monuments. The abbey gatehouse remains, and other fragments may be traced. There are oyster beds in the neighbouring shallow sea.

MINSTER (from Lat. *monasterium*; cf. German *Münster*), the church of a monastery, or one to which a monastery has been attached. In the 10th century the name was applied to the churches of outlying parishes, and is now given to some of the English cathedrals, such as York, Lincoln, Ripon and Southwell, and to large churches or abbeys, like those of Sherborne, Wimborne or Westminster.

MINSTREL. The word "minstrel," which is a derivative from the Latin *minister*, a servant, through the diminutives *ministellus*, *ministrallus* (Fr. *menestrel*), only acquired its special sense of household entertainer late in the 13th century. It was the equivalent of the Low Latin *joculator*[1] (Prov. *joglar*, Fr. *jougleur*, Mid. Eng. *jogclour*), and had an equally wide significance.

The minstrel of medieval England had his forerunners in the Teutonic *scôp* (O.H.G. *scôpf* or *scof*, a shaper or maker), and to a limited extent in the *mimus* of the later Roman empire. The earliest record of the Teutonic *scôp* is found in the Anglo-Saxon poem of *Widsith*, which in an earlier form probably dates back before the English conquest. Widsith, the far-traveller, belonged to a tribe which was neighbour to the Angles, and was sent on a mission to the Ostrogoth Eormanric (Hermanric or Ermanaric, d. 375), from whom he received a collar of beaten gold. He wandered from place to place singing or telling stories in the mead-hall, and saw many nations, from the Picts and Scots in the west to the Medes and Persians in the east. Finally he received a gift of land in his native country. *The Complaint of Deor* and *Beowulf* give further proof that the Teutonic *scôp* held an honourable position, which was shaken by the advent of Christianity. The *scôp* and the gleeman (the terms appear to have been practically synonymous) shared in the general condemnation passed by the Church on the dancers, jugglers, bear-leaders and tumblers. Saxo Grammaticus (*Historia danica*, bk. v.) condemns the Irish king Hugleik because he spent all his bounty on mimes and jugglers. That the loftier tradition of the *scôpas* was preserved in spite of these influences is shown by the tales of Alfred and Anlaf disguised as minstrels. With the Normans came the *joculator* or *jogleur*, who wore gaudy-coloured coats and the flat shoes of the Latin mimes, and had a shaven face and close-cut hair. Jogleurs were admitted everywhere, and enjoyed the freedom of speech accorded to the professional jester. Their impunity, however, was not always maintained, for Henry I. is said to have put out the eyes of Luc de la Barre for lampooning him. A fairly defined class distinction soon arose. Those minstrels who were attached to royal or noble households had a status very different from that of the motley entertainers, who soon came under the restrictions imposed on vagabonds generally. A *joculator regis*, Berdic by name, is mentioned in Domesday Book. The king's minstrels formed part of the royal household, and were placed under a *rex*, a fairly common term of honour in the craft (cf. Adenès li rois). Edward III. had nineteen minstrels in his pay, including three who bore the title of waits. The large towns had in their pay bodies of waits, generally designated in the civic accounts as *histriones*. A wait under Edward III. had to "pipe the watch" four times nightly between Michaelmas and Shere Tuesday, and three times nightly during the remainder of the year. In spite of the repeated prohibitions of the Church, the matter was compromised in practice. Even religious houses had their minstrels, and so pious a prelate as Robert Grosseteste had his private harper, whose chamber adjoined the bishop's. St Thomas Aquinas (*Summa theologia*) said that there was no sin in the minstrel's art if it were kept within the bounds of decency. Thomas de Cabham, bishop of Salisbury (d. 1313), in a *Penitential* distinguished three kinds of minstrels (*histriones*)—buffoons or tumblers; the wandering *scurrae*, by whom he probably meant the goliardi (see GOLIARD); and the singers and players of instruments. In the third class he discriminated between the singers of lewd songs and those *joculatores* who took their songs from the deeds of princes and the lives of saints. The performances of these *joculatores* were permissible, and they themselves were not to be excluded from the consolations of the Church. The Parisian minstrels were formed into a gild in 1321, and in England a charter of Edward IV. (1469) formed the royal minstrels into a gild, which minstrels throughout the country were compelled to join if they wished to exercise their trade. A new charter was conferred in 1604, when its jurisdiction was limited to the city of London and 3 m. round it. This corporation still exists, under the style of the Corporation of the Master, Wardens and Commonalty of the Art or Science of the Musicians of London.

---

[1] Used by John of Salisbury (*Polycraticus*, i. 8) as a generic term to cover *mimi*, *salii* or *salicres*, *balatrones*, *aemiliani*, *gladiatores*, *palaestritae*, *gignadii*, *praestigiatores*.

During the best time of minstrelsy—the 10th, 11th and 12th centuries—the minstrel, especially when he composed his own songs, was held in high honour. He was probably of noble or good bourgeois birth, and was treated by his hosts more or less as an equal. The distinction between the troubadour and the jogleur which was established in Provence probably soon spread to France and England. In any case it is probable that the poverty which forms the staple topic of the poems of Rutebeuf (*q.v.*) was the commonest lot of the minstrel.

Entries of payments to minstrels occur in the accounts of corporations and religious houses throughout the 16th century; but the art of minstrelsy, already in its decline, was destroyed in England by the introduction of printing, and the minstrel of the entertainments given to Elizabeth at Kenilworth was little more than a survival.

The best account of the subject is to be found in E. K. Chambers's *Medieval Stage* (1903), i. 23-86 and ii. 230-266. See also L. Gautier in *Épopées françaises* (vol. ii., 2nd ed., 1892); A. Schultz, *Das höfische Leben zur Zeit der Minnesinger* (2nd ed., 1889); T. Percy, *Reliques of English Poetry* (ed. H. B. Wheatley, 1876); J. Ritson, *Ancient English Metrical Romances* (1802); J. J. Jusserand, *English Wayfaring Life in the Middle Ages* (4th ed., 1892).

MINT, botanically *Mentha*, a genus of labiate plants, comprising about twenty species of perennial herbs, widely distributed throughout the temperate and sub-tropical portions of the globe, but chiefly in the temperate regions of the Old World. The species have square stems, opposite, aromatic leaves, and a stoloniferous creeping rootstock. The flowers are arranged in axillary clusters (cymes), which either form separate whorls or are crowded together into a terminal spike. The corolla is usually small and of a pale purple or pinkish colour; it has four nearly equal lobes, and encloses two long and two short stamens. Nearly three hundred intermediate forms have been named and described. Many of these varieties are permanent, in consequence of being propagated by stolons.

In Britain ten species are indigenous or naturalized. *Mentha viridis*, or spearmint, grows in marshy meadows, and is the species commonly used for culinary purposes; it is distinguished by its smooth, sessile leaves and lax tapering flower-spikes. It is probably a cultivated race of the next species, *Mentha sylvestris*, or horsemint, which chiefly differs from the above in its coarser habit and hairy leaves, which are silky beneath, and in its denser flower-spikes. This plant is supposed to be the mint of Scripture, as it is extensively cultivated in the East; it was one of the bitter herbs with which the paschal lamb was eaten. *M. rotundifolia* resembles the last in size and habit, but is distinguished by its rounded wrinkled leaves, which are shaggy beneath, and by its lanceolate bracts. The last two species usually grow on damp waste ground. *M. aquatica* grows in ditches, and is easily recognized by its rounded flower-spikes and stalked hairy leaves. *M. piperita*, or peppermint (*q.v.*), has stalked smooth leaves and an oblong obtuse terminal spike of flowers; it is cultivated for its volatile oil. *M. pratensis* belongs to a group which have the flowers arranged in axillary whorls and never in terminal spikes; it otherwise bears some resemblance to *M. viridis*. *M. sativa* grows by damp roadsides, and *M. arvensis* in cornfields; they are distinguished from *M. pratensis* by their hairy stalked leaves, which in *M. arvensis* are all equally large, but in *M. sativa* are much smaller towards the apex of the stem. *M. Pulegium*, commonly known as pennyroyal, more rarely as fleamint, has small oval obtuse leaves and flowers in axillary whorls, and is remarkable for its creeping habit and peculiar odour. It differs from all the mints above described in the throat of the calyx being closed with hairs. It is met with in damp places on grassy commons, and was formerly popular for medicinal purposes.

All the genus *Mentha* abound in a volatile oil, contained in resinous dots in the leaves and stems. The odour of the oil is similar in several species, but is not distinctive, the same odour occurring in varieties of distinct species. Thus the peppermint flavour is found in *M. piperita*, in *M. incana*, and in Chinese and Japanese varieties of *M. arvensis*. Other forms of the last-named species growing in Ceylon and Java have the flavour of the common garden mint, *M. viridis*, and the odour is found in *M. sylvestris*, *M. rotundifolia* and *M. canadensis*. A bergamot scent is met with in a variety of *M. aquatica* and in forms of other species. Most mints blossom in August.

The name mint is also applied to plants of other genera, *Monarda punctata* being called horsemint, *Pycnanthemum linifolium* mountain mint, and *Nepeta cataria* catmint.

MINT (Lat. *moneta*; Mid. Eng. *mynt*), a place where coins are manufactured with the authority of the state. Coins are pieces of metal, of weight and composition fixed by law, with a design upon them, also fixed by law, by which they are identified, their value made known and their genuineness certified. The origin of the word "mint" is ascribed to the manufacture of silver coin at Rome in 269 B.C. at the temple of Juno Moneta.[1] This goddess became the personification of money, and her name was applied both to money and to its place of manufacture. Metals were used for money at an early stage of civilization, and are well suited to the purpose, owing to their great intrinsic value and their durability, indestructibility, divisibility and rarity. The best metals for coinage are gold, silver, platinum, copper, tin, nickel, aluminium, zinc, iron, and their alloys; certain alloys of gold, silver, copper and nickel have the best combination of the required qualities.

History of Minting.—The earliest metallic money did not consist of coins, but of unminted metal in the form of rings and other ornaments or of weapons, which were used for thousands of years by the Egyptian, Chaldean and Assyrian Empires (see NUMISMATICS). According to Herodotus, the first mint was probably that established by Gyges in Lydia towards the end of the 8th century B.C. for the coining of gold, silver and electrum, an alloy of gold and silver found in a natural state.[1] Silver was coined in the island of Aegina soon afterwards. The art of coining was introduced by the Greeks into Italy and other countries bordering on the Mediterranean and into Persia and India. Subsequently the Romans laid the foundations of modern minting. Coining originated independently in China at a later date than in the western world, and spread from China to Japan and Korea. Coins may be made by casting in moulds or by striking between engraved dies. The Romans cast their larger copper coins, in clay moulds carrying distinctive markings, not because they knew nothing of striking, but because it was not suitable for such large masses of metal. Casting is now used only by counterfeiters. The most ancient coins were cast in bullet-shaped or conical moulds and marked on one side by means of a die which was struck with a hammer. The "blank" or unmarked piece of metal was placed on a small anvil (*ambos*), and the die was held in position with tongs. The reverse or lower side of the coin received a rectangular mark made by the sharp edges of the little anvil. Subsequently the anvil was marked in various ways, and decorated with letters and figures of beasts, and later still the ambos was replaced by a reverse die. The spherical blanks soon gave place to lenticular-shaped ones. The blank was made red-hot and struck between cold dies. One blow was usually insufficient, and the method was similar to that still used in striking medals in high relief, except that the blank is now allowed to cool before being struck. With the substitution of iron for bronze as the material for dies, about A.D. 300, the practice of striking the blanks while they were hot was gradually discarded.[2] In the middle ages bars of metal were cast and hammered out on an anvil. Portions of the flattened sheets were then cut out with shears, struck between dies and again trimmed with shears. A similar method had been used in Egypt under the Ptolemies (*c.* 300 B.C.) but had been forgotten. Square pieces of metal were also cut from cast bars, converted into round disks by hammering and then struck between dies. In striking, the lower die was fixed into a block of wood, and the blank piece of metal laid upon it by hand. The upper die was then placed on the blank, and kept in position by means of a holder round which was placed a roll of lead to protect the hand of the operator while heavy blows were struck with a hammer. An early improvement was the introduction of a tool resembling a pair of tongs, the two dies being placed one at the extremity of each leg. This avoided the necessity of readjusting the dies between blows, and ensured greater accuracy in the impression. Minting by means of a falling weight (*monkey press*) intervened between the hand hammers and the screw press in many places. In Birmingham in particular this system became highly developed and was long in use. A. Olivier introduced screw presses for striking coins, together with rolls for reducing the cast bars and machines for punching-out round disks from flattened sheets of metal, in Paris in 1553. After being discarded in 1585, except for making medals, they were reintroduced by J. Varin in 1640 and the practice of hammering was forbidden in 1645.[3] In England the new machinery was tried in London in 1561, but abandoned soon afterwards; it was finally adopted in 1662, although the old pieces continued in circulation until 1696. At first the rolls were driven by workmen by means of cranks, but later they were worked by horses, mules or water-power. Steam-power was applied to them by Matthew Boulton and Watt in Birmingham in 1788, and was adopted by the Royal Mint, London, in 1810. Recently the practice of driving rolls by electricity has been growing, the advantage being that each pair of rolls can be driven independently without the intervention of cumbrous shafting. Boulton and Watt's screw press, invented in 1788 and used at the Royal Mint until 1881, was worked by atmospheric pressure applied to a piston. The piston was in communication with a vacuum vessel from which the air had been pumped by steam power.

[1] Lenormant, *La Monnaie dans l'antiquité*, i. 82.

History of British Mints.—In Britain there are evidences of the existence of mints before the arrival of the Romans. Th Romans at first imported their coins, and no Roman mints wer established until about the end of the 3rd century, when coin were being struck at London and Colchester.[4] In Anglo-Saxo times Athelstan appears to have been the first monarch wh enacted regulations for the mints.[5] He promulgated laws abou the year 928, appointing a large number of "moneyers" o "mynteres," London being assigned eight, Canterbury seven other important towns various numbers and all smaller borough one moneyer each. The necessity for so many mints lay i the imperfect means of communication. At an early period probably about A.D. 1000, the dies were made in London an issued to the other mints. The moneyers, who were elected b the burgesses, were responsible for the manufacture of the coin and according to Madox were liable at the time of Henry II. t be summoned to Westminster to take part in the trials of th pyx.[6] If there was any deficiency in the weight of the fineness of the coin the moneyers were punished as traitors. These moneyers appear to have been abolished about 1180,[7] whe officers were appointed to supervise the coinage on behalf of th king, and the name "moneyer" was applied to contractors wh manufactured the coin under superintendence and were no responsible to the king for its weight and fineness. The moneyer continued to manufacture the coin of the realm until the yea 1850, when the work was entrusted to civil servants. In th reign of Henry III. the principal officers of the Mint were th master, who manufactured the coin under a contract, the warde or paymaster who acted on behalf of the Crown, the assay maste (also a king's officer) who was responsible for the fineness of th coin, the cuneator or superintendent of the engravers of the dies and the moneyer. One of the most important duties of th warden was the collection from the contractor of the seigniorag which was claimed by the sovereign by virtue of his prerogativ as a source of revenue to the Crown. In 1718 Sir Isaac Newto was made master of the Mint, and in that capacity as contracto for the coinage he amassed a considerable fortune.[8] As the work of the Mint became more extensive and more complicated othe officers were added and their duties were varied from time t time. The present administration of the English Mint is base on arrangements made in 1870, when the establishment was reorganized. The office of master of the Mint is held by the chancellor of the exchequer for the time being, without salary, but th actual administrative work of the department is entrusted t the deputy master and comptroller. The receipt of bullion an the delivery of coin from the Mint is under the charge of the chie clerk, the manufacture of coin is in the hands of the superintendent of the operative department, and the valuation of th bullion by assay, and matters relating to the fineness of th coin are entrusted to the chemist and assayer. The date of th establishment of the Mint in the Tower of London is unknown There is a reference to it dated 1229 and a clear reference date 1329.[9] According to Ruding, there were over fifty mints in th reign of Edward the Confessor. After the Norman Conques the mints increased to about seventy, a greater numbe than now exists in the world, but they were gradually reduce and in the reign of Edward I. there were only twelve Ruding enumerates 128 mints operated at various times in th United Kingdom, including some established by usurpation, a in the reign of Stephen by certain barons, and also mints established by grants to ecclesiastics to be worked for their own profit The provincial mints were all closed just before the reign o Mary, who coined in London only. Charles I. set up small mint in various towns, and for the great re-coinage in the reign o William III. mints were established at York, Chester, Exeter Bristol and Norwich, but were soon abandoned. Wood's coppe money for Ireland and America was coined at Wolverhampto (1700–1722), and the tradesmen's tokens were struck at variou towns. Copper coins were struck by Boulton at Soho, Birmingham in 1788, and a colonial bronze coinage was executed at this establishment as recently as the year 1875. There is another mint in Birmingham worked by a private company ("The Mint, Birmingham, Limited"), where coinages for foreign governments are executed and in addition silver and bronze colonial coins are occasionally manufactured under the supervision of the London Mint. The existing London Mint was erected on Tower Hill in 1810. Minting in Scotland began in the reign of David I. (1124–1153) and ceased in 1709, two years after the Act of Union, in which it had been expressly stipulated that a mint should be continued in Scotland.[1] Coinage in Dublin began in Anglo-Saxon times and came to an end in the reign of William III.[2] The other Irish mints were of little importance.

British Dominions.—Turning to mints in British Dominions beyond the Seas, Ruding enumerates twenty-six mints in France and Flanders used by British monarchs between 1186 and 1513, and Anglo-Hanoverian coins were struck at Clausthal, Zellerfeld and Hanover in the period 1714–1837. In India[3] the earliest English mint was that at Madras which was bought by the East India Company in 1620, reorganized more than once and finally closed in 1869. The Calcutta mint was established by the East India Company in 1757, but other mints in Bengal continued to be used till about 1835, when the Calcutta mint was rebuilt. The Bombay mint was set up about the year 1671, but the coins were made by hammer and anvil until 1800. The Calcutta and Bombay mints are still in operation. A mint was opened in Hong-Kong in 1866 but was closed in 1868 and the machinery sold to Japan. In Australia there are three mints, Sydney, opened in 1855, Melbourne, opened in 1872, and Perth, opened in 1899. Up to 1909 only sovereigns and half-sovereigns were struck at these establishments, but in 1910 arrangements were made for a Commonwealth silver coinage. A mint at Ottawa was opened in 1908 for the manufacture of all Canadian coins as well as English sovereigns.

Other Countries.—In the United States the Philadelphia mint was opened in 1792, but only manual or horse power was used until 1836, when steam was introduced. Other mints are now in operation at New Orleans, San Francisco and Denver. In most European countries a single mint situated at the capital is found to be sufficient, but there are six mints in the German Empire and two in Austria-Hungary. In China 26 mints were at work in 1906. There are also mints at Osaka, Bangkok and Teheran, and the Seoul mint was at work in 1904. In Mexico 11 mints formerly existed, but one only, in the city of Mexico, remained open in 1907. In South America there are mints at Lima, Santiago, Buenos Ayres and Tegucigalpa. No mints are in operation in Africa. In all there are nearly 70 mints in the world.

The Supply of Bullion to Mints.—In England, in the middle ages, the king was accustomed to send in to the mint the produce of his own silver mines, and claimed the exclusive privilege of purchasing the precious metals. The right of levying seigniorage, however, was sometimes waived by the king to encourage his subjects to bring gold and silver to the mint, and several instances are recorded in which the aid of alchemists was called in to effect the transmutation of baser metals into gold. Seigniorage was abolished for both gold and silver in 1666, when it was provided that no charge should be made at the Mint for coining and assaying. Finally in 1816 the free coinage of silver was brought to an end. At present all gold bullion brought to the Mint is weighed and portions are cut off for assay. The amount of gold in standard ounces (916·6 fine) corresponding to the "imported" bullion is thus ascertained, and on the application of the importer the gold is coined and delivered to him in the form of sovereigns and half-sovereigns at the rate of £3, 17s. 10½d. per standard ounce troy, no deduction being made for wastage, seigniorage, the purchase of alloy metal, or the expense of manufacture. As a considerable time elapses between the receipt of bullion by the Mint and the delivery of the coin, it is generally more profitable for the holder of gold bullion to sell it to the Bank of England or dispose of it in some other way. The result is that the gold presented for coinage is almost always sent from the Bank of England, which suffers no loss of interest during the coinage of the bullion, because bank-notes have already been issued against it. Silver bullion, and the copper, tin and zinc required to make up bronze, are bought by the Mint and manufactured into coin, which is kept in stock and issued as it may be required. One ounce of standard silver, which contains 925 parts of silver and 75 of copper per 1000, is converted into 5s. 6d. in silver coin, whatever may be the market price of silver bullion. This seldom exceeded 30d. per ounce in the years 1893–1907. Coinage bronze consists of copper 95 parts, tin 4 parts and zinc 1 part, and a ton yields £448 in pence or £373, 6s. 8d. in halfpence or farthings. The difference between the nominal value of silver and bronze coin and its intrinsic value is retained by the state to cover the expenses of manufacture and as a source of profit. It corresponds to the seigniorage levied by the king on all coinages down to the reign of Charles II. In return, the Mint receives at its nominal value for recoinage the worn gold and silver coin which is withdrawn from circulation by the Bank of England and some other banks. In spite of the cost of this recoinage, however, the profit on the issue of new silver and bronze usually exceeds in each year the total expenditure of the Mint. Gold and silver are delivered in a refined state suitable for immediate conversion into coin. In general, only old coin, ingots resulting from the melting of coin, and "fine" ingots are received. Fine gold ingots (the "bar gold" of commerce) are usually about 400 oz. troy in weight, and contain from 990 to 999·5 parts of gold per 1000, the remainder being chiefly silver. Fine silver ingots usually weigh from 1000 to 1200 oz. troy and contain from 995 to 999 parts of silver per 1000. The ingots are valued by weighing and assaying, and a calculation is made as to the amount of copper required for melting with them to produce the standard alloy. The two standard alloys consist respectively of gold 916·6, copper 83·3 and of silver 925, copper 75. All gold coins received at the Bank are weighed on automatic balances (see below) and those below the lowest legal current weight are separated. The lowest current weight is 122·5 grains for sovereigns and 61·125 grains for half-sovereigns corresponding to losses by wear of about 0·6% and 0·8% respectively. The average age on withdrawal is about 24 years for sovereigns and 15 years for half-sovereigns. Silver coins are not weighed but are selected for withdrawal when they present a worn appearance. The average deficiency in weight of worn silver coin received at the Mint is from 8 to 10%, and the mean age somewhat less than 50 years. In European mints generally little difficulty is experienced in procuring refined gold and silver for coinage. In Australia, the United States, Japan and some other countries, the Mints receive unrefined gold from the mines and refine it before it is coined. A charge for refining is made in all cases. A refinery was attached to the London Mint from 1816 to 1851, but was then let on lease and left to private enterprise. The operations employed in the manufacture of gold and silver coin are as follow:—

(1) Melting the metal and casting it into bars. (2) Rolling the bars into strips or "fillets." (3) Cutting out disks or blanks from the fillets. (4) Adjusting the weight of the blanks (this is omitted in some mints). (5) "Marking" or edge-rolling the blanks to produce a raised rim or to impress a design on the edge. (6) Annealing the blanks and (in some mints) cleaning them in acid. (7) Striking the blanks between dies surrounded by a collar. (8) Weighing each coin. Among the incidental operations are (*a*) the valuation of the bullion by weighing and assaying it; (*b*) "rating" the bullion, or calculating the amount of copper to be added to make up the standard alloy; (*c*) recovering the values from ground-up crucibles, ashes and floor sweepings (the Mint "sweep"); (*d*) assaying the melted bars; (*e*) "pyxing" the finished coin or selecting specimens to be weighed and assayed; (*f*) "telling" or counting the coin.

Melting.—Formerly bullion was melted in crucibles made of refractory clay, but they are liable to crack and require careful handling

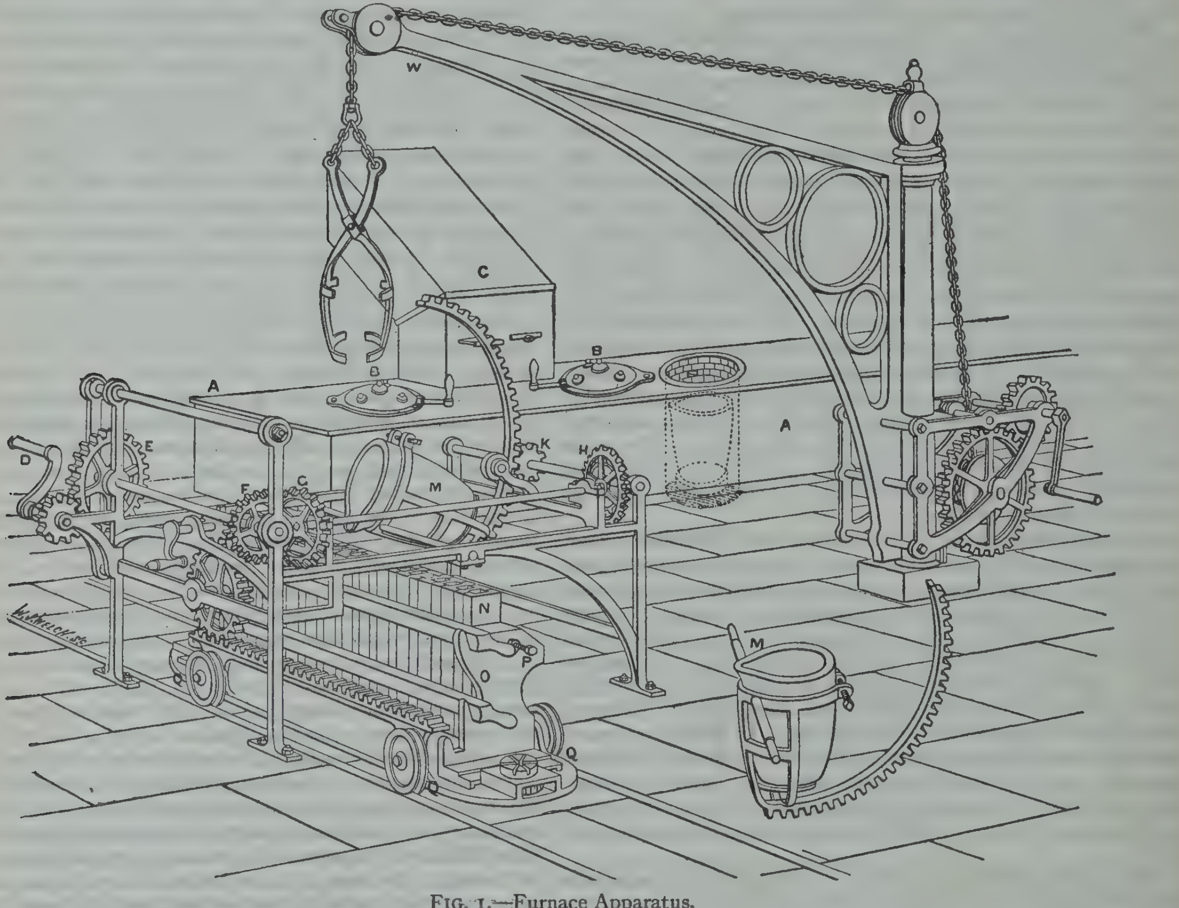

FIG. 1.—Furnace Apparatus.

These were succeeded by iron crucibles, especially for melting silver, and these have now been generally replaced by graphite (plumbago) crucibles made of a mixture of clay and graphite. Good graphite crucibles can be used many times in succession if they are heated gradually each time, but they are usually discarded after about fifteen or twenty meltings. At the Royal Mint gold is melted in crucibles about 10 in. in height and 8½ in. in diameter at the widest part. The charge is from 1200 to 1300 oz. (37·3 to 40·5 kilograms) of metal. The furnace is 12 in. square and 2 ft. deep from the fire-bars to the cover. An old crucible is cut off about 2 in. from the bottom and the bottom piece is inverted and placed on the fire-bars as a support for the crucible. The "muffle," a graphite cylinder 6 in. in height, is placed on the crucible to allow room for long bars to be melted in the crucible and to prevent the surrounding coke from falling into it. The flue, of about 5 in. square, communicates with a stack 60 ft. high. In many mints the flues pass into condensing chambers where volatilized gold and silver are recovered. The crucible is at a red heat when the gold is charged in, the copper being added last, and a graphite lid put on the crucible to check loss by volatilization. The charge is completely melted in about half an hour, and it is then thoroughly mixed by stirring with a graphite rod. The crucible is then lifted out by circular tongs suspended in such a way that two men can take part in the operation. The contents are poured by hand into moulds which are contained side by side in an iron carriage running on wheels, fig. 1, OP. The molten gold, which is of a pale green colour, solidifies at once in the iron moulds, and the bars can be taken out immediately. Bars from which sovereigns are to be coined are 22 in. long, 1⅝ in. wide and ⅓ in. thick, and about seven such bars are cast from one pot. The rough edges of the bars are removed by a circular revolving file, and the hollow ends are cut off. Pieces are cut out for assay, and the bars are then ready for rolling. The amount of gold melted in an ordinary day's work is two tons to two and a half tons, of the value of £250,000 to £300,000. For silver larger crucibles are used, containing about 5000 oz. troy (155 kilograms). They are heated in circular furnaces 21 in. in diameter and lifted out with circular tongs suspended from a travelling crane which is worked by electricity. The crucible is placed in the pouring cradle, which has been in use since 1816, and is shown in fig. 1. Here A is the iron cover surrounding the furnaces, B is the revolving lid of a furnace, and C is the flue, common to two furnaces and leading to the stack. The handle D, acting through the gear wheels E, F, G and H, turns the cogwheel K, which moves the curved rack of the cradle and tips the crucible M. The molten metal is poured into the moulds N, which are carried on wheels running on rails Q. The parts of the range of moulds are brought tightly together and held in position by the bars O and the screw P, and when one mould is filled the carrier is moved forward on its rails by wheels worked by a handle also shown in the figure. In some other mints still larger crucibles are used, containing various amounts up to about 1000 kilograms or over 30,000 oz. In foreign mints the molten metal is generally transferred from the crucible to the moulds by dipping crucibles or iron ladles covered with clay. Gas is used as fuel for the melting furnaces at Philadelphia. It is cleaner than coke and is said to save time and to reduce the loss of the precious metals. At Denver and Ottawa the fuel used is "first distillate" oil, which is found to be cheaper than either naphtha or gas. The oil is pumped from buried tanks and warmed to about 90° F. before it reaches the burners at the furnaces. At the Denver mint the crucibles are used for from twelve to fifteen meltings with oil fuel, whereas they were soon destroyed when gas was employed. A charge of 6000 oz. of gold is melted in about an hour. The melting losses amount to about 0·2 per 1000 of gold and 0·6 per 1000 of silver in the Royal Mint. The losses are caused by volatilization, by the absorption of metal by the crucible, stirring rod, &c., and by occasional projection of particles from the pot into the furnace. The ash-pit is lined with iron plates to facilitate the recovery of metal accidentally spilt. All crucibles and other materials which might contain precious metal are ground up and washed in a pan, and the pannings together with a selection from the floor sweepings are remelted. The residues (the Mint "sweep") are sold to refiners or ore-smelters.

Rolling.—The cast bars are reduced to the thickness of the coin by repeated passages between rolls. These are cylinders of cast iron or steel from 6 in. to 15 in. in diameter set parallel to one another with a small interval between, and revolved by electric or steam power. They are divided into breaking-down and finishing rolls, the latter being of smaller diameter than the former. The power is usually transmitted through toothed wheels, each roll being driven independently in some cases, while sometimes power is applied to the lower roll only, the upper roll being coupled to it. The of many foreign coins, are put on by the marking machine, and a plain collar is used in striking.

The coining presses now used are all modifications of the lever press invented by Uhlhorn of Grevenbroich near Cologne in 1839. The press in use at the Royal Mint since 1882 is shown in figs. 6 and 7. The lever M worked from the front of the machine causes the fly-wheel to be connected with the driving-wheel and the machine starts. The blanks are placed in the slide J and the lowest one is carried forward to the die in two successive movements of the "layer-on" K, a rod working backwards and forwards on a horizontal plate and actuating the finger L, fig. 8. The lower die is firmly fixed to the bed of the machine, and the blank is placed exactly upon it. The collar A′ is then raised by the lever G so as to encircle the blank, and the upper die which is held at A is brought down. This is done by the little crank B on the axle of the fly-wheel, acting through the rod C, and the bent lever D, which forms a toggle-joint at E with the vertical piece of metal below it. The straightening of the toggle-joint when C is pushed forward forces A down to strike the coin. The reverse movement of D lifts up the upper die and the collar drops simultaneously so that its upper surface is level with the face of the lower die on which the finished coin lies. Another blank moved on by the finger L pushes off the finished coin which falls down the tube N. The diagram, fig. 9, shows the relative position of the dies and levers more clearly. The dies and collar are shaded. The presses at the Mint strike from 90 to 125 coins per minute, most of them working at the rate of 110 coins per minute. There are 19 presses and it is possible with these to strike between 700,000 and 800,000 pieces in an ordinary working day.

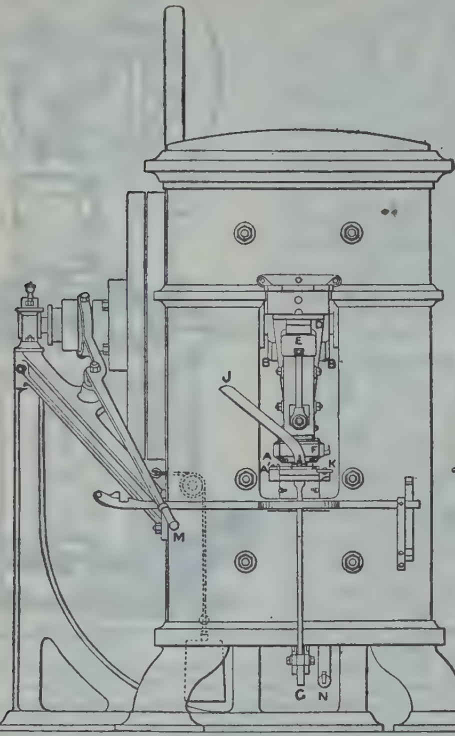

Fig. 6.

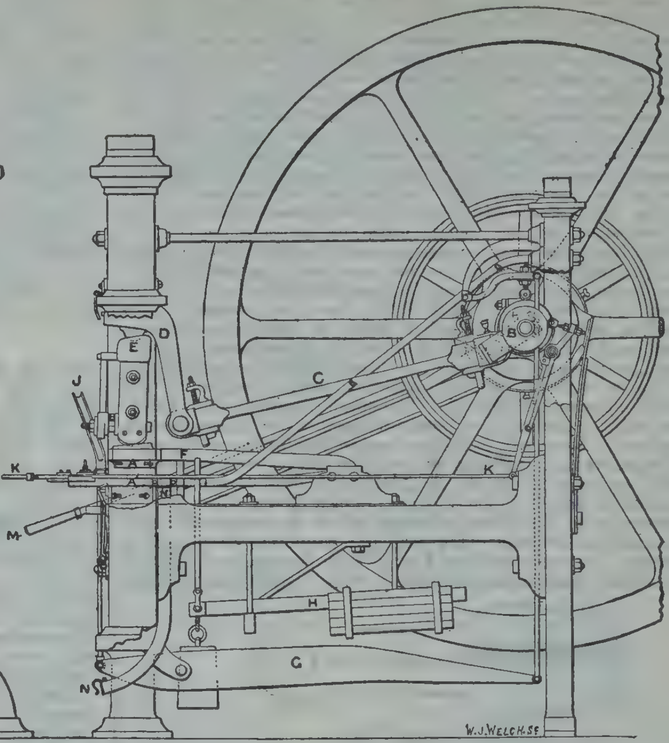

Fig. 7.

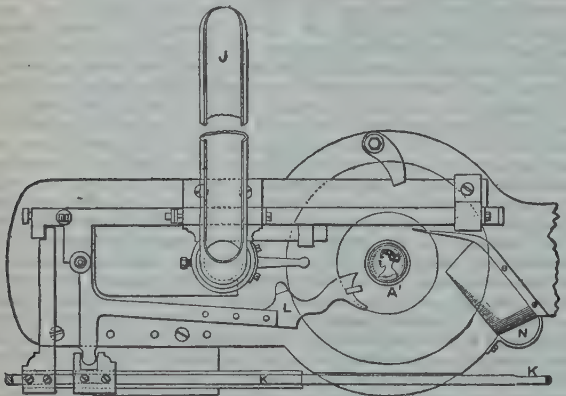

Fig. 8.

Weighing the Coins.—Gold and silver coins are examined and tested by ringing, and each coin is then weighed separately by being passed over delicate automatic balances. The first automatic balance for weighing single coins was introduced at the Bank of England in 1843, and was designed by William Cotton, the deputy governor of the Bank. In 1851 these balances, improved by Richard Pilcher, were introduced at the Royal Mint, and modifications of them are now used at most foreign mints. For mint use it is necessary that they shall distinguish between "light," "heavy" and "good" coins which do not differ from standard by more than the small weight known as the "remedy" (see above). The balances used in the Royal Mint were further improved by J. T. Butler in the year 1889. The balance consists essentially of a beam with two scale pans, one for the coin and the other for the counterpoise. The beam is released and in the course of a second or so takes up a certain position dependent on the relative weights of the coin and counterpoise. Its position is then fixed by an automatic grip, and the coin falling down a shoot enters one of three compartments of a box, according to the position of the beam when it is arrested. The chief working parts are shown in fig. 10. The beam A is of steel made in one piece, about 11 in. long. Its centre and end knife edges are shown in fig. 11. The scale pan for the coin is shown in fig. 12. B is the pan on which the coin rests, at a point above the beam. The coins are placed in a rouleau in the hopper C and the lowest one is pushed on to the pan B by a slide not shown in the figure. While the coin is being moved the hanger D is held firmly by the forceps E to prevent the pan from being pushed sideways. The forceps are then opened and the beam released, but at this moment the levelling bar F is allowed to drop momentarily by a bent lever G acting on the pin G′, until the ends of F press down on a stirrup in each hanger at H, H. This brings the beam to a horizontal position. The lever G at once

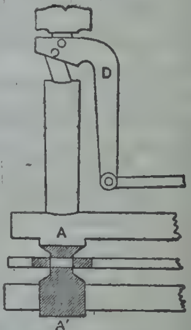

Fig. 9.

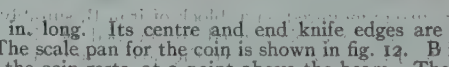

Fig. 10

lifts the bar F again by acting on the pin G′ so that the bar F does not touch the stirrups at H and the beam and hangers are free to move. The coin is balanced by the brass counterpoise J on the left-hand hanger and by little weights made of wire attached to the right-hand hanger at K. If the coin is heavier than the lowest legal weight (that is, the standard weight less the remedy) the right-hand side of the beam begins to fall and the left-hand one is raised. This movement proceeds until the stirrup L below the left-hand hanger is raised far enough to touch the rod M, which is equal in weight to twice the remedy. The movement is then stopped provided that the weight of the coin is not greater than the standard weight plus the remedy. If it is heavier than this, it raises the weight M, and the movement of the beam and its hangers proceeds farther in the same direction. After about a second from the time of the final release of the beam, the forceps E again close and the hanger D is held firmly in its new position. The rod N is then lowered and allows the indicating finger O, which is pivoted at P, to fall until it rests on the stirrup R, which is part of the hanger D. The extension of O holds down the right-hand end of the rod S which is also pivoted at P, and enables its end to fit into one of the three inverted steps on the bottom of the shoot Q. The position of the shoot is thus determined. It stops over one of three orifices in the bottom plate of the balance. If the coin is light the rod S fits into the uppermost step and the shoot stops over the right-hand slot. If the coin is heavy, S fits into the lowest step and the shoot stops over the left-hand slot. The middle step and slot are for coins within the remedy. The movement of the slide now pushes another coin forward, and the weighed coin is displaced by it and falls down the shoot, through one of the slots. Each slot leads into a separate compartment and the coins are consequently sorted into three classes, light, correct weight and heavy. The balance turns to 0·01 grain. The driving power is applied by shafting through a number of cams. In the Royal Mint both light and heavy coins are returned to the melting pot. The proportion of rejected gold coin varies with the quality of the bullion, and frequently exceeds 10%. The percentage of rejected silver is often no more than 1%. In most foreign mints the blanks are weighed by the automatic balances before being struck, and those which are too heavy are reduced by filing or planing. A workman sitting at a balance files the edges of the piece and weighs it until it is within the remedy. The blank is then again passed through the automatic balance and is sent forward to the coining press if the correctness of the weight is confirmed. Since 1870 no adjusting of the weight of coins has been attempted at the Royal Mint. Heavy blanks have also been reduced chemically by making them part of the anode in a cyanide bath through which a current of electricity is passed. Some metal from the surface of each blank then passes into solution, and the blanks are reduced in weight with remarkable uniformity. This system was introduced into the Indian mints in 1873.

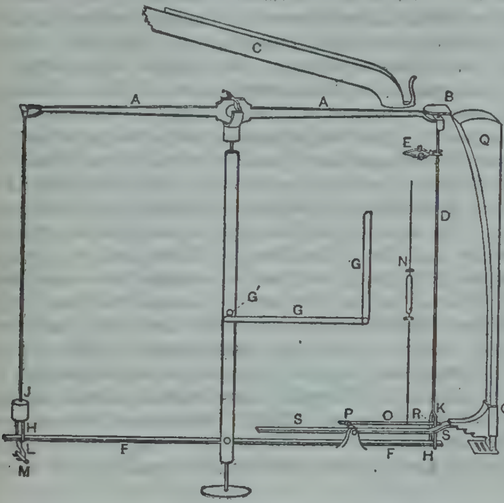

FIG. 11.

FIG. 12.

Telling.—The coin is counted and packed into bags for despatch from the Mint. The counting or telling is now carried out in the case of bronze and silver coins by ingenious machines introduced in 1891. The coins are spread on an inclined table by hand. They slide down the table and enter a narrow passage where only one can pass at a time, jamming being prevented by the joggling action of an eccentric rotating disk at the entrance to the passage. The coins are then gripped by a pair of india-rubber driving wheels, which force them past the rim of a thin disk with notches in its edge to fit the coins. As the disk is thus made to revolve, the coins are pushed forward, and falling down a shoot are received in a bag. The machine can be set to deliver a certain number of coins, after which the counting wheel stops automatically.

Trial of the Pyx.—Periodical examinations of the coins issued by the Mint have been made from very early times in England by persons appointed by the Crown. Specimens are selected from the finished coin and are put into a box or "pyx." At intervals these coins are weighed and assayed by a jury of skilled persons and the results reported to the Crown. A trial of the pyx is mentioned in the Lansdowne MSS. as having taken place in the reign of Henry II., but the practice had probably originated much earlier. The trial is now held annually by a jury consisting of freemen of the Company of Goldsmiths. Coins from the London and Australian mints are examined. The Company has been entrusted with the duty since the time of James I. Coins of foreign mints are generally submitted to examination by a committee of eminent chemists and metallurgists whose report is published in the official journals.

A full account of the work of the Mint, with valuable tables giving the amount of the coinage of gold and silver and bronze in the United Kingdom and the colonies in detail, and a *résumé* of the coinages of foreign countries, will be found in the *Annual Reports of the Deputy Master and Comptroller of the Mint*, which have been published since 1870. (T. K. R.)

MINTO, EARLS OF. The Scottish border family of Elliot which has held the earldom of Minto since 1813 has had many distinguished members. Sir Gilbert Elliot, bart. (1651–1718), and his son and successor, another Sir Gilbert Elliot (1693–1766), were both celebrated Scottish judges and both took the official title of Lord Minto. The elder Sir Gilbert was sentenced to death for his share in the rising of the earl of Argyll in 1685, but was afterwards pardoned; the younger Sir Gilbert was a scholar and an agriculturist. Among the children of the latter were John Elliot (d. 1808), a naval officer, who served as governor of Newfoundland and was made an admiral; Andrew Elliot, the last English governor of New York; and the poetess Jean, or Jane, Elliot (*c.* 1727–1805), who wrote the popular ballad "Flowers of the Forest." The eldest son, Sir Gilbert Elliot (1722–1777), who became the third baronet in April 1766, was a member of parliament from 1753 to 1777, and a friend and follower of the earl of Bute. He filled several public offices, and Horace Walpole said he was "one of the ablest members of the House of Commons." His second son was the diplomatist, Hugh Elliot (1752–1830), who represented his country at Munich, at Berlin, at Copenhagen and at Naples. He was governor of Madras from 1814 to 1820, and he died on the 10th of December 1830.

See the *Memoirs of the Right Hon. Hugh Elliot*, by the countess of Minto (Edinburgh, 1868).

The third baronet's eldest son was GILBERT ELLIOT, 1st earl of Minto (1751–1814). About 1763 Gilbert and his brother Hugh were sent to Paris, where their studies were supervised by David Hume and where they became intimate with Mirabeau. Having passed the winters of 1766 and 1767 at Edinburgh University, Gilbert entered Christ Church, Oxford, and on quitting the university he was called to the bar. In 1776 he entered parliament as an independent Whig. He became very friendly with Burke, whom he helped in the attack on Warren Hastings and Sir Elijah Impey, and on two occasions was an unsuccessful candidate for the office of speaker. In 1794 Elliot was appointed to govern Corsica, and in 1797 he assumed the additional names of Murray-Kynynmond and was created Baron Minto. From 1799 to 1801 he was envoy-extraordinary to Vienna, and having been for a few months president of the board of control he was appointed governor-general of India at the end of 1806. He governed with great success until 1813. He was then created Viscount Melgund and earl of Minto. He died at Stevenage on the 21st of June 1814 and was buried in Westminster Abbey.

The earl's second son was Admiral Sir George Elliot (1784–1863), who as a youth was present at the battles of Cape St Vincent and the Nile, and who was secretary to the admiralty from 1830 to 1834. A nephew of the earl was Sir Charles Elliot (1801–1875) also an admiral, who took a prominent part in the war with China in 1840. Afterwards he was governor of Bermuda, of Trinidad and of St Helena.

GILBERT ELLIOT-MURRAY-KYNYNMOND, 2nd earl of Minto (1782–1859), eldest son of the 1st earl, was ambassador to Berlin from 1832 to 1834, first lord of the admiralty from 1835 to 1841 and lord privy seal from 1846 to 1852. His influence in the Whig party was partly due to the fact that his daughter, Frances, was the wife of Lord John Russell.

His son William Hugh, the 3rd earl (1814–1891), was the father of the 4th earl, Gilbert John Elliot-Murray-Kynynmond (1845–), who joined the Scots Guards in 1867. In 1874, in the capacity of a newspaper correspondent, he witnessed the operations of the Carlists in Spain; he took service with the Turkish army in the war with Russia in 1877 and served under Lord Roberts in the second Afghan War (1878–79), having narrowly escaped accompanying Sir Louis Cavagnari Kabul. He acted as private secretary to Lord Roberts during his mission to the Cape in 1881; as military secretary to Lord Lansdowne during his governor-generalship of Canada from 1883 to 1885; and as chief of the staff to General Middleton in the Riel Rebellion in Canada (1885). Having succeeded to the earldom in 1891 he was appointed governor-general of Canada in 1898. His term of office (1898–1904) was distinguished by a visit of the prince and princess of Wales to the colonies. In 1905, on the resignation of Lord Curzon, Lord Minto was appointed viceroy and governor-general of India, retiring in 1910.

The 4th earl's brother, the Hon. Arthur Ralph Douglas Elliot (b. 1846), editor of the *Edinburgh Review*, was a member of parliament from 1880 to 1892 and again from 1898 to 1906, and from 1903 to 1906 he was financial secretary to the treasury. Sir Francis Edmund Hugh Elliot (b. 1851), a grandson of the 2nd earl, became British minister at Athens in 1903.

See Hon. G. F. S. Elliot, *The Border Elliots and the Family of Minto* (Edinburgh, 1897); the article India; *History*; also the *Life and Letters of the first Earl of Minto, 1751–1806* (1874) and *Lord Minto in India, 1807–1814* (1880), both edited by the countess of Minto; and Sir J. F. Stephen, *The Story of Nuncomar and the Impeachment of Sir E. Impey* (1885).

MINTO, WILLIAM (1845–1893), Scottish man of letters, was born at Auchintoul, Aberdeenshire, on the 10th of October 1845. He was educated at Aberdeen University, and spent a year at Merton College, Oxford. He was assistant professor under Alexander Bain at Aberdeen for some years; from 1874 to 1878 he edited the *Examiner*, and in 1880 he was made full professor of logic and English at Aberdeen. In 1872 he published a *Manual of English Prose Literature*, which was distinguished by sound judgment and sympathetic appreciation; and his *Characteristics of English Poets from Chaucer to Shirley* (1874) showed the same high qualities. His other works include: *The Literature of the Georgian Era* (1894) edited with a biographical introduction by W. Knight a monograph on Defoe in the *English Men of Letters* series (1879); three novels of small importance, and numerous articles on literary subjects in the 9th edition of the *Encyclopaedia Britannica*. He died on the 1st of March 1893.

MINTURNAE, an ancient city of the Aurunci, in Italy, situated on the N.W. bank of the Liris with a suburb on the opposite bank 1½ m. from its mouth, at the point where the Via Appia crossed it by the Pons Tiretius. It was one of the three towns of the Aurunci which made war against Rome in 314 B.C., the other two being Ausona (see Sessa Aurunca) and Vescia; and the Via Appia was made two years later. It became a colony in 295 B.C. In 88 B.C. Marius in his flight from Sulla hid himself in the marshes of Minturnae. The ruins consist of an amphitheatre (now almost entirely demolished, but better preserved in the 18th century), a theatre, and a very fine aqueduct in *opus reticulatum*, the quoins of which are of various colours arranged in patterns to produce a decorative effect. Close to the mouth of the river was the sacred grove of the Italic goddess Marica. It is still mentioned in the 6th century, but was probably destroyed by the Saracens, and its low site, which had become unhealthy, was abandoned in favour of that of the modern town of Minturno (known as Traetto until the 19th century), 459 ft. above sea-level. A tower at the mouth of the river, erected between 961 and 981, commemorates a victory gained by Pope John X. and his allies over the Saracens in 915. It is built of Roman materials from Minturnae, including several inscriptions and sculptures.

See T. Ashby in *Mélanges de l'École française de Rome* (1903), 413; R. Laurent-Vibert and A. Piganol, ibid. (1907), p. 495; G. Q. Giglioli, *Notizie degli Scavi* (1908) p. 396. (T. As.)

MINUCIUS, FELIX MARCUS, one of the earliest if not the earliest, of the Latin apologists for Christianity. Of his personal history nothing is known, and even the date at which he wrote can be only approximately ascertained. Jerome (*De vir. ill* 58) speaks of him as "Romae insignis causidicus," but in this he is probably only improving on the expression of Lactantius (*Inst. div.* v. 1) who speaks of him as "non ignobilis inter causidicos loci." He is now exclusively known by his *Octavius*, a dialogue on Christianity between the pagan Caecilius Natalis[1] and the Christian Octavius Januarius, a provincial lawyer, the friend and fellow-student of the author. The scene is pleasantly and graphically laid on the beach at Ostia on a holiday afternoon, and the discussion is represented as arising out of the homage paid by Caecilius, in passing, to the image of Serapis. His arguments for paganism (possibly modelled on those of Celsus) are taken up seriatim by Octavius, with the result that the assailant is convinced. Minucius himself plays the part of umpire. The form of the dialogue is modelled on the *De natura deorum* and *De divinatione* of Cicero and its style is both vigorous and elegant if at times not exempt from something of the affectation of the age. Its latinity is not of the specifically Christian type. If the doctrines of the Divine unity, the resurrection, and future rewards and punishments be left out of account, the work has less the character of an exposition of Christianity than of a philosophical and ethical polemic against the absurdities of polytheism. While it thus has much in common with the Greek Apologies it is full of the strong common sense that marks the Latin mind. Its ultimate appeal is to the fruits of faith.

The *Octavius* is admittedly earlier than Cyprian's *Quod idola dii non sint*, which borrows from it; how much earlier can be determined only by settling the relation in which it stands to Tertullian's *Apologeticum*. Since A. Ebert's exhaustive argument in 1868, repeated in 1889, the priority of Minucius has been generally admitted; the objections are stated in the *Dict. Chr. Biog.* article by G. Salmon. Editions: F. Sabaeus-Brixianus, as Bk. viii. of Arnobius (Rome, 1543); F. Balduinus, first separate edition (Heidelberg, 1560); Migne, *Patrol. Lat.* iii. 239; Halm in *Corp. Scr. Eccl. Lat.* (Vienna, 1867); H. A. Holden. Translations: R. E. Wallis, in *Ante-Nic. Fathers*, vol. iv.; A. A. Brodribb's *Pagan and Puritan*. Literature: In addition to that already cited see H. Boenig's art. in Hauck-Herzog's *Realencyk.* vol. 13, and the various histories of early Christian Literature by A. Harnack, G. Krüger, A. Ehrhard and O. Bardenhewer.

MINUET (adapted, under the influence of the Italian *minuetto*, from Fr. *menuet*, small, pretty, delicate, a diminutive of *menu*, from Lat. *minutus*; the word refers probably to the short steps, *pas menus*, taken in the dance), a dance for two persons, in $\frac{3}{4}$ time. At the period when it was most fashionable it was slow, ceremonious, and graceful (see Dance). The name is also given to a musical composition written in the same time and rhythm, but when not accompanying an actual dance the pace was quicker. An example of the true form of the minuet is to be found in Don Giovanni. The minuet is frequently found as one of the movements in the Suites of Handel and Bach. Haydn introduced it into the symphony, with little trace of the slow grace and ceremony of the dance. In the hands of Beethoven it becomes the scherzo.

MINUSINSK, a town of Russia, in East Siberia, and the government of Yeniseisk, 180 m. S.S.W. of Krasnoyarsk railway station, and 5 m. from the right bank of the Yenisei, in a fertile prairie region. Pop. (1897), 10,255. It is a centre for trade with the native populations of the Sayan Mountains and north-western Mongolia. It has an excellent natural history, ethnographical and archaeological museum (1877), with a library and a meteorological station. Coal and iron abound in the vicinity.

---

[1] This name occurs in six inscriptions of the years 211–217 found at Constantine (Cirta), North Africa (*C.I.L.* vol. viii.). Like the other North African fathers Tertullian, Cyprian, Arnobius and Lactantius, he was a lawyer. Some use may have been made of rhetorical expressions of M. Cornelius Fronto of Cirta (d. *c.* A.D. 170).

MINUTE (Lat. *minutus*, small; *minuere*, to make less), an adjective meaning of very small size, petty or trifling; also extremely precise. In this sense the word is pronounced *mī-nūte*. As a substantive and pronounced *minnit* the word (usually in the plural) is applied to a written summary of the transactions of a meeting of a public or other body, or to a memorandum of instructions, &c. A Treasury minute in the United Kingdom is an official memorandum authorizing certain procedure. "To minute" is to draw up such a summary or memorandum. More particularly, "minute" is used of the sixtieth part of any unit); in time, of an hour; and in astronomy, geometry, geography, &c., of a degree in the measurement of a circle. The sexagesimal system of division was originally used by the ancient Babylonian astronomers, was adopted by Ptolemy; and the sixtieth part of a degree, and its further subdivision into sixty parts, was called in Latin *pars minutae primae*, and *pars minutae secundae* respectively, hence the English "minute" and "second."

MINUTE MEN: in the American War of Independence, militiamen who had undertaken to turn out for service at a minute's notice. In Massachusetts the minute men were enrolled by an act of the provincial congress of the 23rd of November 1774, and in Boston alone they numbered 16,000 prior to the outbreak of the war. The Americans who fought in the opening action of Lexington were "minute men."

MIOCENE, in geology, the system of strata which occurs between the Oligocene and the Pliocene. The term, derived from the Greek μεῖον, less, and καινός, recent, was introduced by Sir Charles Lyell, as indicating palaeontologically a less percentage of recent species than is found in the Pliocene. Variable lacustrine, estuarine and marine deposits, especially characterized by soft calcareous sandstones and conglomerates ("molasse") and sandy shell-beds ("faluns"), make up the Miocene system of the Neogene or newer Tertiary in Europe and western Asia, where it attains its fullest development.

A. de Lapparent's classification is here adopted:—

V. *Pontian* or *Pannonian*.—Brackish- and fresh-water marls, limestones and gravels: occurring at Vienna, in the Caspian and eastern Mediterranean basins, and in southern France; mammalian deposits of Pikermi and the Siwalik Hills, with *Hipparion gracile*, *Mastodon longirostris*, *Rhinoceros schleiermachi*, numerous ruminants, *Congeria subglobosa*. Marine beds of Belgium (Black Crag) and north Germany.

IV. *Sarmatian*.—More or less salt-water sands and marls of the same basins with *Mastodon angustidens*, *Anchitherium aurelianense*, *Cerithium pictum*, *C. rubiginosum*, *Ostrea gingensis*, *Mactra podolica*, *Tapes gregarius*. Stages IV. and V. represented in north-western France by marine sands (*Cardita striatissima*), and in Algeria and Morocco by marine marls and limestones.

III. *Vindobonian*.—Sub-stages:—

(*b*) *Tortonian*: Marine marls with *Ancillaria glandiformis*, *Conus antiquus*, *Ranella marginata*, *Trochus patulus*, *Voluta rarispina*. Laminated fresh-water limestones of Oeningen with fish, countless insects, and plants showing seasonal changes of the year in their successive layers (*Acer trilobatum*, *Populus mutabilis*, *Juglans acuminata*, *Camphora*, *Podogonium*); and the lacustrine deposits of central Spain.

(*a*) *Helvetian*: Marine shelly sandstones and conglomerates ("molasse" of Switzerland) with *Ostrea gingensis*, *Cardita jouanneti*, *Panopaea menardi*, *Conus ventricosus*; the "faluns" of Touraine and Aquitaine; and the marine beds of Black Sea basin. At the base of the marine Helvetian in the Vienna basin clays ("Schlier") with rock-salt and gypsum, and the lacustrine beds of Gascony (*Calcaire de Simorre* with *Mastodon tapiroides*, *M. simorrensis*, *Dinotherium giganteum*) occur.

II. *Burdigalian* or *Langhian*.—Marine "faluns" of Bordeaux (*Oliva basteroti*, *Turritella terebralis*); marls of Langhe in Liguria (*Pecten burdigalensis*); marine deposits of Vienna basin, Caspian region, Tunis and Algeria; fresh-water sands and marls of Orleans with *Mastodon angustidens*, *M. tapiroides*, *Dinotherium cuvieri*, *Anthracotherium onoideum*; *Littorinella* clays of Mainz basin with *Acerotherium incisivum Littorinella acuta*, *Dreyssenia brardi*; fresh-water grey "molasse" of Switzerland, with acacias, laurels, palms and sequoias.

I. *Aquitanian*.—Limestones, sands and marls of lakes and lagoons, with *Anthracotherium*, *Anchitherium*, *Acerotherium incisivum*, *Palaeochoerus typus*, *Helix ramondi*, *Limnaea pachygaster*, *Planorbis cornu*, *Potamides lamarcki*; *Quercus*, *Acacia*, *Ficus*, *Camphora*, *Cinnamomum*, *Taxodium*, *Glyptostrobus*, *Sequoia*, *Sabal*, *Phoenix*, occur in central France (*Calcaire de la Beauce*); the plant-beds of Manosque; Mainz basin; lower "molasse" of Switzerland with lignite, gypsum, red marls and conglomerates; "brown-coal series" of north Germany with lignite. Intercalated marine sandstones occur in Aquitaine and near Marseilles; other marine developments occur in the "faluns" of Gascony (*Lepidocyclina mantelli*, *Miogypsina burdigalensis*), the upper Aquitanian of Bavaria and Austria-Hungary (*Ostrea crassiassima*, *Pectunculus pilosus*), and in southern Spain, Italy and Malta (*Lepidocyclina* and *Lithothamnium*). Basic tuffs and lavas occur in Auvergne.

Some authors assign Stage I. to the Oligocene, Stage V. to the Pliocene; Stages I. and II. correspond to the first, and III. to the second Mediterranean Stage of E. Suess.

In Europe a general emergence of land in late Oligocene time resulted at the beginning of the Miocene (Aquitanian) in widespread lacustrine conditions throughout the western part of that continent, upon which the sea encroached at few points, though it had gained access to the Vienna basin and extended westward into Bavaria. Otherwise, marine Aquitanian deposits are confined to the Mediterranean basin and the south-west corner of France. Most of northern Europe, including the British Isles, remained dry land throughout Miocene time. During the Burdigalian period, with increasing elevation of the mountain regions and depression of the Mediterranean and Caspian basins, a marine invasion began, which passed its maximum in the Vindobonian. The Mediterranean reached eastward to Persia, and, still open to the Atlantic, submerged north Africa, most of Italy and the neighbouring islands. It ascended the Rhone valley, penetrated to the Mainz basin, and skirting the north flank of the Alpine region passed into the Vienna basin and thence around the Carpathian tract into the Pontic and Caspian depression. The waters of the Atlantic further invaded the regions of the Garonne and the Loire, isolated Brittany and encroached upon north Europe between Belgium and Denmark.

The elevation of the Alps, and probably of the whole Alpine system of mountain folds from Morocco to Indo-China, though initiated by earlier Miocene and late Oligocene movements, took place mainly during the latter part of the Vindobonian period, and was completed in the Sarmatian. The waters of the ocean were then excluded from the Caspian and eastern Mediterranean basins, and replaced by vast fresh-water lakes; while brackish-water lagoons occupied much of the western Mediterranean. This great retreat of the sea culminated in the Pontian stage, and land-connexion was established between North and South America. Outside the Eurasian region, Aquitanian deposits occur in Formosa, Java, Borneo and Madagascar; while Burdigalian deposits are found in Mongolia. The Vindobonian ranges from Greenland, Iceland and Spitzbergen, where it contains lignite and plants denoting a temperate climate, by Japan, Java and India, to Victoria. It recurs in the Azores and the Antilles, and at intervals along the American continent from Patagonia to Alaska, where all three lower stages are represented, as also in the West Indies. Along the Atlantic slope of the United States and around the Gulf of Mexico the complete Miocene series is present, the Sarmatian and Pontian also occur in California.

The Miocene was a period of change, of mountain-building, climatic differentiation hitherto unprecedented, and of moderation in organic life, especially on land. The rich European flora indicates an equable and moist sub-tropical climate, slowly cooling, as witnessed by the gradual increase of trees with deciduous foliage amongst those characteristic of more tropical conditions. Oaks, maples, poplars, planes, willows, *Cinnamomum*, *Camphora*, *Myrica*, *Sequoia*, *Taxodium*, *Glyptostrobus* and palms, flourished together. The marine calcareous alga *Lithothamnium* became an important reef-building organism. Nummulites gave place to *Lepidocyclina*; lamellibranchs and particularly gasteropods abounded in the shallow seas, of which the shark *Carcharodon* and the marine mammals *Squalodon* and *Halitherium* were amongst the largest denizens. The mammalian land-fauna of Europe made striking advances, and assumed a decidedly African aspect. Marsupials had disappeared from it before the Burdigalian period, during which primitive genera like *Palaeochoerus*, *Hyopotamus*, and the hornless ruminants *Anthracotherium* and *Brachyopus*, became extinct, while proboscideans (*Mastodon*, *Dinotherium*), rhinoceros and apes (*Oreopithecus*, *Pliopithecus*) came in, followed by antelopes, beavers and probably *Machaerodus* in the Vindobonian. The spread of turf-forming grasses was succeeded in the Pontian by an enormous increase of herbivorous mammals, including *Hipparion* and horned ruminants (*Helladotherium*, *Antilope*, *Cervus*, *Camelopardalis*, *Palaeotragus*), whose migrations were facilitated by the desiccation of the Mediterranean basin. (C. B. W.*)

MIOT DE MÉLITO, ANDRÉ FRANÇOIS, Comte (1762–1841), French statesman and scholar, was born at Versailles (Seine-et-Oise) on the 9th of February 1762. He was a high official in the war office before the Revolution, and under the Republic he eventually became secretary-general for foreign affairs. That he was not denounced under the Terror was due to the fact that he was indispensable in his department. In 1795 he was sent as French envoy to Florence; then to Rome, and on his return to Florence received orders to proceed to Corsica, which, after its evacuation by the British, was in a state of anarchy. In Corsica he allied himself with Joseph Bonaparte, and after pacifying the island returned to Italy. Recalled by their Dectory in 1798 because of his refusal to foment insurrection in Italy, he spent some time in retirement, but he was in the diplomatic service in Holland at the revolution of 18. Brumaire (Nov. 9, 1799). Under the consulate he was secretary-general at the ministry of war, and a member of the council of state, and was sent on a second mission (1801–1802) for the pacification of Corsica. In 1806 he joined Joseph Bonaparte in Naples as minister of the interior, afterwards following him to Spain as comptroller of the household, but he returned to France in the retreat of 1813. Next year he was created comte de Mélito, and during the Hundred Days he served as commissary extraordinary with the XII. Army division. He took no part in politics after Waterloo, where his son-in-law, General J. B. Jamin, was killed, and his own son mortally wounded. He visited Joseph Bonaparte in America in 1825, and then spent some years in Germany with his daughter, whose second husband, General von Fleischmann, represented the king of Württemburg in Paris in 1831. He was admitted in 1835 to the French Academy on the merits of his translations of Herodotus (Paris, 1822) and Diodorus (Paris, 1835–1838). He died in Paris on the 5th of January 1841.

Miot de Mélito had kept a diary which, arranged for publication by his son-in-law, General von Fleischmann, covers the years from 1788 to 1815, and is of interest for the history of the Bonaparte family and of Joseph's dominion in Spain. Published in France in 1858, it was translated into English by Mrs C. Hoey and J. Lillie (2 vols., 1881); and also into German (Stuttgart, 1866–1867). See Albert Gaudin, *Les Arrêtés Miot* (Ajaccio, 1896).

MIQUEL, JOHANN VON (1829–1901), German statesman, was born at Neuenhaus, Hanover, on the 19th of February 1829, being descended from a French family which had emigrated during the Revolution. He learnt law at the universities of Heidelberg and Göttingen. Studying the writings of Karl Marx he became a convert to an extreme revolutionary, socialistic and atheistic creed; but though he entered into correspondence with Marx, with the object of starting a revolutionary movement, he does not appear to have taken any overt part in the events of 1848–1849. Further study of political economy soon enabled him to pass out of this phase, and in 1850 he settled down to practise as an advocate at Göttingen. He acquired repute as an able lawyer and a rising politician, and especially for his knowledge of financial questions. He was one of the founders of the German *Nationalverein*, and in 1864 he was elected a member of the Hanoverian parliament as a Liberal and an opponent of the government. He accepted the annexation of Hanover by Prussia without regret, and was one of the Hanoverians whose parliamentary abilities at once won a commanding position in the Prussian parliament, which he entered in 1867. For some reason—perhaps because Bismarck did not entirely trust him—he did not at this time attain quite so influential a position as might have been anticipated; nevertheless he was chairman of the parliamentary committee which in 1876 drafted the new rules of legal procedure, and he found scope for his great administrative abilities in the post of burgomaster of Osnabrück. He held this position from 1865 to 1870, and again from 1876 to 1879, being in the meantime (1870–1873) a director of the Discontogesellschaft. In 1879 he was elected burgomaster of Frankfort-on-Main, where he gained a great reputation for the energy with which he dealt with social questions, especially that of the housing of the poor. Probably owing to his early study of socialism, he was very ready to support the new state socialism of Bismarck. He was the chief agent in the reorganization of the National Liberal party in 1887, in which year he entered the imperial Reichstag. After Bismarck's fall in 1890 he was chosen Prussian minister of finance, and held this post for ten years. He distinguished himself by his reform of the Prussian system of taxation, the one really successful measure of the new reign in internal affairs. An attempt, however, to reform the system of imperial finance in 1893–1894 failed, and much injured his reputation. Miquel had entirely given up his Liberalism, and aimed at practical measures for improving the condition of the people irrespective of the party programmes; yet some of his measures—such as that for taxing "Waarenhäuser" (stores)—were of a very injudicious nature. He professed to aim at a union of parties on the basis of the satisfaction of material interests, a policy to which the name of *Sammlung* was given; but his enemies accused him of constantly intriguing against the three chancellors under whom he served, and of himself attempting to secure the first place in the state. The sympathy which he expressed for the Agrarians increased his unpopularity among Liberals and industrials; but he pointed out that the state, which for half a century had done everything to help manufactures, might now attempt to support the failing industry of agriculture. In June 1901 the rejection of the canal bill led to a crisis, and he was obliged to send in his resignation. His health was already failing, and he died on the 8th of September of the same year at his house in Frankfort.

MIQUELETS (MIQUELETES or MIGUELETES) were irregular local troops in Catalonia who derived their name, it is said, from Miguel or Miquelot de Prats, a Catalan mercenary captain in the service of Cesare Borgia. They enjoyed a certain prominence in the minor wars of Spain during the 17th and 18th centuries, and in peace seem to have plundered travellers. In the War of the Spanish Succession (*q.v.*) the Miquelets continued the struggle against the French claimant until long after the peace. During the Peninsular War they were exceedingly successful in harassing the French invaders in the mountains of Catalonia. Sometimes they even attempted operations in large bodies, as in the operations round Gerona in 1808 and 1809. They were maintained by the several parishes, not by the central or the provincial governments, and as they had to turn out for duty on sound of the village alarm-bell (*somaten*) they are frequently called *somatenes*.

MIRABEAU, ANDRÉ BONIFACE LOUIS RIQUETI, VICOMTE DE (1754–1792), brother of the orator Mirabeau, was one of the reactionary leaders at the opening of the French Revolution. Sent to the army in Malta in 1776 he spent part of his two years there in prison for insulting a religious procession. During the War of American Independence he was in several sea-fights with the English, and was at the taking of Yorktown in 1781. In the following year he had two narrow escapes from drowning. In 1789, with his debts paid up by his father, he was elected by the noblesse of Limoges a deputy to the States General. He was a violent Conservative and opposed everything that threatened the old régime. His drunkenness produced a corpulency which brought him the nickname Mirabeau Tonneau ("Barrel Mirabeau"); but he was not lacking in some of that insight which marked his brother. He shared fully in the eccentric family pride; and boasted of his brother's genius even when bitterly opposing him. He emigrated about 1790, and raised a legion which was to bear his name; but his insolence alienated the German princes, and his command was taken from him. He died in August 1792—of apoplexy or from a duel—in Freiburg im Breisgau. He wrote some verse as well as various pamphlets.

See Joseph Sarrazin, *Mirabeau Tonneau, ein Condottiere aus der Revolutionszeit* (Leipzig, 1893); and *La Révolution française*, vols. xxi. and xxiv.; Eugène Berger, *Le Vicomte de Mirabeau* (*Mirabeau Tonneau*), *1754–1792* (1904); and for a list of contemporary pamphlets, &c., M. Tourneux, *Bibliographie de la ville de Paris* . . ., vol. iv. (1906).

MIRABEAU, HONORÉ GABRIEL RIQUETI, COMTE DE (1749–1791), French statesman, was born at Bignon, near Nemours, on the 9th of March 1749. The family of Riquet, or Riqueti, originally of the little town of Digne, won wealth as merchants at Marseilles, and in 1570 Jean Riqueti bought the château and seigniory of Mirabeau, which had belonged to the great Provençal family of Barras. In 1685 Honoré Riqueti obtained the title of marquis de Mirabeau. His son Jean Antoine served with distinction through all the later campaigns of the reign of Louis XIV., and especially distinguished himself in 1705 at the battle of Cassano, where he was so severely wounded in the neck that he had ever after to wear a silver stock; yet he never rose above the rank of colonel, owing to an eccentric habit of speaking unpleasant truths to his superiors. On retiring from the service he married Françoise de Castellane, and left at his death, in 1737, three sons—Victor marquis de Mirabeau, Jean Antoine, bailli de Mirabeau, and Comte Louis Alexandre de Mirabeau. The great Mirabeau was the eldest surviving son of the marquess. When but three years old he had a virulent attack of small-pox which left his face disfigured, and contributed to his father's dislike of him. Being destined for the army, he was entered at a pension militaire at Paris. Of this school, which had Lagrange for its professor of mathematics, we have an amusing account in the life of Gilbert Elliot, 1st earl of Minto, who with his brother Hugh, afterwards British minister at Berlin, there made the acquaintance of Mirabeau. On leaving this school in 1767 he received a commission in a cavalry regiment which his grandfather had commanded years before. He at once began love-making, and in spite of his ugliness succeeded in winning the heart of the lady to whom his colonel was attached; this led to such scandal that his father obtained a *lettre de cachet*, and the young scapegrace was imprisoned in the isle of Rê. The love affairs of Mirabeau form a well-known history, owing to the celebrity of the letters to Sophie. Yet it may be asserted that until the more durable and more reputable connexion with Mme de Nehra these love episodes were the most disgraceful blemishes in a life otherwise of a far higher moral character than has been commonly supposed. As to the marquess, his use of *lettres de cachet* is perfectly defensible on the theory of *lettres de cachet*, and Mirabeau, if any son, surely deserved such correction. Further, they had the effect of sobering the culprit, and the more creditable part of his life did not begin till he left Vincennes. Mirabeau did not develop his great qualities of mind and character until his youthful excesses were over, and it was not till 1781 that these began to appear. On being released, the young count obtained leave to accompany as a volunteer the French expedition to Corsica. After his return, he tried to keep on good terms with his father, and in 1772 he married a rich heiress, Marie Emilie, daughter of the marquess de Marignane, an alliance procured for him by his father. His wild extravagance, however, forced his father to forestall his creditors by securing his detention in semi-exile in the country, where he wrote his earliest extant work, the *Essai sur le despotisme*. His violent disposition now led him to quarrel with a country gentleman who had insulted his sister, and his semi-exile was changed by *lettre de cachet* into imprisonment in the Château d'If. In 1775 he was removed to the castle of Joux, to which, however, he was not very closely confined, having full leave to visit in the town of Pontarlier. Here he met Marie Thérèse de Monnier, his Sophie as he called her. Of his behaviour nothing too strong can be said: he was introduced into the house as a friend, and betrayed his trust by inducing Mme de Monnier to fall in love with him. The affair ended by his escaping to Switzerland, where Sophie joined him; they then went to Holland, where he lived by hack-work for the booksellers; meanwhile Mirabeau had been condemned to death at Pontarlier for *rapt et vol*, and in May 1777 he was seized by the French police, and imprisoned by a *lettre de cachet* in the castle of Vincennes.

During his imprisonment he seems to have learnt to control his passions from their very exhaustion, for the early part of his confinement is marked by the indecent letters to Sophie (first published in 1793), and the obscene *Erotica biblion* and *Ma conversion*, while to the later months belongs his political work of any value, the *Lettres de cachet*, published after his liberation (1782). It exhibits an accurate knowledge of French constitutional history skilfully applied in an attempt to show that an existing actual grievance was not only philosophically unjust but constitutionally illegal. It shows, though in rather a diffuse and declamatory form, that application of wide historical knowledge, keen philosophical perception, and genuine eloquence to a practical purpose which was the great characteristic of Mirabeau, both as a political thinker and as a statesman.

With his release from Vincennes (August 1782) begins the second period of Mirabeau's life. He found that his Sophie was an idealized version of a rather common and ill-educated woman, and she consoled herself with the affection of a young officer, after whose death she committed suicide. Mirabeau first set to work to get the sentence of death still hanging over him reversed, and by his eloquence not only succeeded in this but got M. de Monnier condemned in the costs of the whole law proceedings. From Pontarlier he went to Aix, where he claimed the court's order that his wife should return to him. She naturally objected, but his eloquence would have won his case, even against Jean Etienne Marie Portalis, the leader of the Aix Bar, had he not in his excitement accused his wife of infidelity, on which the court pronounced a decree of separation. He then intervened in the suit pending between his father and mother before the parlement of Paris, and attacked the ruling powers so violently that he had to leave France and again go to Holland, and try to live by literary work. About this time began his connexion with Mme de Nehra, the daughter of Zwier van Haren, a Dutch statesman and political writer, and a woman of a far higher type than Sophie, more educated, more refined, and more capable of appreciating Mirabeau's good points. His life was strengthened by the love of his *petite horde*, Mme de Nehra, his adopted son, Lucas de Montigny, and his little dog Chico. After a period of work in Holland he betook himself to England, where his treatise on *lettres de cachet* had been much admired, being translated into English in 1787, and where he was soon admitted into the best Whig literary and political society of London, through his old schoolfellow Gilbert Elliot, who had now inherited his father's baronetcy and estates, and become a leading Whig member of parliament. Of all his English friends none seem to have been so intimate with him as the 1st marquess of Lansdowne, better known as Lord Shelburne, and Mr, afterwards Sir Samuel, Romilly. The latter became particularly attached to him, and really understood his character; and it is strange that his remarks upon Mirabeau in the fragment of autobiography which he left, and Mirabeau's letters to him, should have been neglected by French writers. Romilly was introduced to Mirabeau by Sir Francis D'Ivernois (1757–1842), and readily undertook to translate into English the *Considérations sur l'ordre de Cincinnatus*, which Mirabeau had written in 1785. Romilly writes thus of him in his autobiography:—

> "The count was difficult enough to please; he was sufficiently impressed with the beauties of the original. He went over every part of the translation with me, observed on every passage in which justice was not done to the thought or the force of the expression lost, and made many useful criticisms. During this occupation we had occasion to see one another often, and became very intimate; and, as he had read much, had seen a great deal of the world, was acquainted with all the most distinguished persons who at that time adorned either the royal court or the republic of letters in France; had a great knowledge of French and Italian literature, and possessed very good taste, his conversation was extremely interesting and not a little instructive. I had such frequent opportunities of seeing him at this time, and afterwards at a much more important period of his life, that I think his character was well known to me. I doubt whether it has been so well known to the world, and I am convinced that great injustice has been done him. This, indeed, is not surprising, when one considers that, from the first moment of his entering upon the career of an author, he had been altogether indifferent how numerous or how powerful might be the enemies he should provoke. His vanity was certainly excessive; but I have no doubt that, in his public conduct as well as in his writings, he was desirous of doing good, that his ambition was of the noblest kind, and that he proposed to himself the noblest ends. He was, however, like many of his countrymen, who were active in the calamitous Revolution which afterwards took place, not sufficiently scrupulous about the means by which those ends were to be accomplished. He indeed to some degree professed this; and more than once I have heard him say that there were occasions upon which 'la petite morale était ennemie de la grande.' It is not surprising that with such maxims as these in his mouth, unguarded in his expressions and careless of his reputation, he should have afforded room for the circulation of many stories to his disadvantage."

This luminous judgment, it must be noted, was written by a man of acknowledged purity of life, who admired Mirabeau in early life not when he was a statesman, but when he was only a struggling literary man. The *Considérations sur l'ordre* *de Cincinnatus* which Romilly translated was the only important work Mirabeau wrote in the year 1785, and it is a good specimen of his method. He had read a pamphlet published in America attacking the proposed order, which was to form a bond of association between the officers who had fought in the American War of Independence against England; the arguments struck him as true and valuable, so he re-arranged them in his own fashion, and rewrote them in his own oratorical style. He soon found such work not sufficiently remunerative to keep his *petite horde* in comfort, and then turned his thoughts to employment from the French foreign office, either in writing or in diplomacy. He first sent Mme de Nehra to Paris to make peace with the authorities, and then returned himself, hoping to get employment through an old literary *collaborateur* of his, Durival, who was at this time director of the finances of the department of foreign affairs. One of the functions of this official was to subsidize political pamphleteers, and Mirabeau had hoped to be so employed, but he ruined his chances by a series of writings on financial questions. On his return to Paris he had become acquainted with Étienne Clavière, the Genevese exile, and a banker named Panchaud. From them he heard plenty of abuse of stock-jobbing, and seizing their ideas he began to regard stock-jobbing, or agiotage, as the source of all evil, and to attack in his usual vehement style the Banque de St Charles and the Compagnie des Eaux. This last pamphlet brought him into a controversy with Caron de Beaumarchais, who certainly did not get the best of it, but it lost him any chance of literary employment from the government. However, his ability was too great to be neglected by a great minister such as Charles Gravier, Comte de Vergennes undoubtedly was, and after a preliminary tour to Berlin at the beginning of 1786 he was despatched in July 1786 on a secret mission to the court of Prussia, from which he returned in January 1787, and of which he gave a full account in his *Histoire secrète de la cour de Berlin* (1789). The months he spent at Berlin were important in the history of Prussia, for while he was there Frederick the Great died. The letters just mentioned show clearly what Mirabeau did and what he saw, and equally clearly how unfit he was to be a diplomatist. He certainly failed to conciliate the new king Frederick William; and thus ended Mirabeau's one attempt at diplomacy. During his journey he had made the acquaintance of Jakob Mauvillon (1743–1794), whom he found possessed of a great number of facts and statistics with regard to Prussia; these he made use of in a great work on Prussia published in 1788. But, though his *De la monarchie prussienne sous Frédéric le Grand* (London, 1788) gave him a general reputation for historical learning, he had in the same year lost a chance of political employment. He had offered himself as a candidate for the office of secretary to the Assembly of Notables which the king had just convened, and to bring his name before the public published another financial work, the *Dénonciation de l'agiotage*, which abounded in such violent diatribes that he not only lost his election, but was obliged to retire to Tongres; and he further injured his prospects by publishing the reports he had sent in during his secret mission at Berlin. But 1789 was at hand; the states-general was summoned; Mirabeau's period of probation was over.

On hearing of the king's determination to summon the states-general, Mirabeau started for Provence, and offered to assist at the preliminary conference of the noblesse of his district. They rejected him; he appealed to the *tiers état*, and was returned both for Aix and for Marseilles. He elected to sit for the former city, and was present at the opening of the states-general on the 4th of May 1789. From this time the record of Mirabeau's life forms the best history of the first two years of the Constituent Assembly, for at every important crisis his voice is to be heard, though his advice was not always followed. He possessed at the same time great logical acuteness and the most passionate enthusiasm. From the beginning he recognized that government exists in order that the bulk of the population may pursue their daily work in peace and quiet, and that for a government to be successful it must be strong. At the same time he thoroughly comprehended that for a government to be strong it must be in harmony with the wishes of the majority of the people. He had carefully studied the English constitution in England, and he hoped to establish in France a system similar in principle but without any slavish imitation of the details of the English constitution. In the first stage of the history of the states-general Mirabeau's part was very great He was soon recognized as a leader, to the chagrin of Jean Joseph Mounier, because he always knew his own mind, and was prompt in emergencies. To him is to be attributed the successful consolidation of the National Assembly. When the taking of the Bastille had assured the success of the Revolution, he warned the Assembly of the futility of passing fine-sounding decrees and urged the necessity for acting. He declared that the famous night of the 4th of August was but an orgy, giving the people an immense theoretical liberty while not assisting them to practical freedom, and overthrowing the old régime before a new one could be constituted. His failure to control the theorizers showed Mirabeau, after the removal of the king and the Assembly to Paris, that his eloquence would not enable him to guide the Assembly by himself, and that he must therefore try to get some support. He wished to establish a strong ministry, which should be responsible like an English ministry, but to an assembly chosen to represent the people of France better than the English House of Commons at that time represented England. He first thought of becoming a minister at a very early date, if we may believe a story contained in the *Mémoires* of the duchesse d'Abrantes, to the effect that in May 1789 the queen tried to bribe him, but that he refused this and expressed his wish to be a minister. The indignation with which the queen repelled the idea may have made him think of the duke of Orleans as a possible constitutional king, because his title would of necessity be parliamentary. But the weakness of Orleans was too palpable, and in a famous remark Mirabeau expressed his utter contempt for him. He also attempted to form an alliance with Lafayette, but the general was as vain and as obstinate as Mirabeau himself, and had his own theories about a new French constitution. Mirabeau tried for a time, too, to act with Necker, and obtained the sanction of the Assembly to Necker's financial scheme, not because it was good, but because, as he said, "no other plan was before them, and something must be done."

Hitherto weight has been laid on the practical side of Mirabeau's political genius; his ideas with regard to the Revolution after the 5th and 6th of October must now be examined, and this can be done at length, thanks to the publication of Mirabeau's correspondence with the Comte de la Marck, a study of which is indispensable for any correct knowledge of the history of the Revolution between 1789 and 1791. Auguste Marie Raymond, prince d'Arenberg, known as the Comte de la Marck, was a Flemish nobleman who had been proprietary colonel of a German regiment in the service of France; he was a close friend of the queen, and had been elected a member of the states-general. His acquaintance with Mirabeau, begun in 1788, ripened during the following year into a friendship, which La Marck hoped to turn to the advantage of the court. After the events of the 5th and 6th of October he consulted Mirabeau as to what measures the king ought to take, and Mirabeau, delighted at the opportunity, drew up an admirable state paper, which was presented to the king by Monsieur, afterwards Louis XVIII. The whole of this *Mémoire* should be read to get an adequate idea of Mirabeau's genius for politics; here it must be summarized.

The main position is that the king is not free in Paris; he must therefore leave Paris and appeal to France. "Paris n'en veut que l'argent; les provinces demandent des lois." But where must the king go? "Se retirer à Metz ou sur toute autre frontière serait déclarer la guerre à la nation et abdiquer le trône. Un roi qui est la seule sauvegarde de son peuple ne fuit point devant son peuple; il le prend pour juge de sa conduite et de ses principes." He must then go towards the interior of France to a provincial capital, best of all to Rouen, and there he must appeal to the people and summon a great convention. It would be ruin to appeal to the noblesse, as the queen advised: "un corps de noblesse n'est point une armée, qui puisse combattre." When this great convention met the king must show himself ready to recognize that great changes have taken place, that feudalism and absolutism have for ever disappeared, and that a new relation between king and people has arisen, which must be loyally observed on both sides for the future. "Il est certain, d'ailleurs, qu'il faut une grande révolution pour sauver le royaume, que la nation a des droits, qu'elle est en chemin de les recouvrer tous, et qu'il faut non seulement les rétablir, mais les consolider." To establish this new constitutional position between king and people would not be difficult, because "l'indivisibilité du monarque et du peuple est dans le cœur de tous les Français; il faut qu'elle existe dans l'action et le pouvoir."

Such was Mirabeau's programme, from which he never diverged, but which was far too statesmanlike to be understood by the poor king, and far too positive regarding the altered condition of the monarchy to be palatable to the queen. Mirabeau followed up his *Mémoire* by a scheme of a great ministry to contain all men of mark—Necker as prime minister, "to render him as powerless as he is incapable, and yet preserve his popularity for the king," the duc de Liancourt, the duc de la Rochefoucauld, La Marck, Talleyrand, bishop of Autun, at the finances, Mirabeau without portfolio, G. J. B. Target, mayor of Paris, Lafayette generalissimo to reform the army, Louis Philippe, comte de Ségur (foreign affairs), Mounier and I. R. G. le Chapelier. This scheme got noised abroad, and was ruined by a decree of the Assembly of the 7th of November 1789, that no member of the Assembly could become a minister; this decree destroyed any chance of that necessary harmony between the ministry and the majority of the representatives of the nation which existed in England, and so at once overthrew Mirabeau's hopes. The queen utterly refused to take Mirabeau's counsel, and La Marck left Paris. However, in April 1790 he was suddenly recalled by the comte de Mercy-Argenteau, the Austrian ambassador at Paris, and the queen's most trusted political adviser, and from this time to Mirabeau's death he became the medium of almost daily communications between the latter and the queen. Mirabeau at first attempted again to make an alliance with Lafayette, but it was useless, for Lafayette was not a strong man himself and did not appreciate "la force" in others. From the month of May 1790 to his death in April 1791 Mirabeau remained in close and suspected, but not actually proved, connexion with the court, and drew up many admirable state papers for it. In return the court paid his debts; but it ought never to be said that he was bribed, for the gold of the court never made him swerve from his political principles—never, for instance, made him a royalist. He regarded himself as a minister, though an unavowed one, and believed himself worthy of his hire.

Before Mirabeau's influence on foreign policy is discussed, his behaviour on several important points must be noticed. On the great question of the veto he took a practical view, and seeing that the royal power was already sufficiently weakened, declared for the king's absolute veto and against the compromise of the suspensive veto. He knew from his English experiences that such a veto would be hardly ever used unless the king felt the people were on his side, and that if it were used unjustifiably the power of the purse possessed by the representatives of the people would, as in England in 1688, bring about a bloodless revolution. He saw also that much of the inefficiency of the Assembly arose from the inexperience of the members and their incurable verbosity; so, to establish some system of rules, he got his friend Romilly to draw up a detailed account of the rules and customs of the English House of Commons, which he translated into French, but which the Assembly, puffed up by a belief in its own merits, refused to use. On the great subject of peace and war he supported the king's authority, and with some success. Again Mirabeau almost alone of the Assembly held that the soldier ceased to be a citizen when he became a soldier; he must submit to be deprived of his liberty to think and act, and must recognize that a soldier's first duty is obedience. With such sentiments, it is no wonder that he approved of the vigorous conduct of François Claude Amour, marquis de Bouillé, at Nancy, which was the more to his credit as Bouillé was the one hope of the court influences opposed to him. Lastly, in matters of finance he showed his wisdom: he attacked Necker's "caisse d'escompte," which was to have the whole control of the taxes, as absorbing the Assembly's power of the purse; and he heartily approved of the system of assignats, but with the reservation that they should not be issued to the extent of more than one-half the value of the lands to be sold.

Of Mirabeau's attitude with regard to foreign affairs it is necessary to speak in more detail. He held it to be just that the French people should conduct their Revolution as they would, and that no foreign nation had any right to interfere with them while they kept themselves strictly to their own affairs. But he knew also that neighbouring nations looked with unquiet eyes on the progress of affairs in France, that they feared the influence of the Revolution on their own peoples, and that foreign monarchs were being prayed by the French emigrés to interfere on behalf of the French monarchy. To prevent this interference, or rather to give no pretext for it, was his guiding thought as to foreign policy. He had been elected a member of the *comité diplomatique* of the Assembly in July 1790, and became its reporter at once, and in this capacity he was able to prevent the Assembly from doing much harm in regard to foreign affairs. He had long known Armand Marc, comte de Montmorin, the foreign secretary, and, as matters became more strained from the complications with the princes and counts of the empire, he entered into daily communication with the minister, advised him on every point, and, while dictating his policy, defended it in the Assembly. Mirabeau's exertions in this respect are not his smallest title to the name of statesman; and how great a work he did is best proved by the confusion which ensued in this department after his death. For indeed in the beginning of 1791 his death was very near; and he knew it to be so. The wild excesses of his youth and their terrible punishment had weakened his strong constitution, and his parliamentary labours completed the work. So surely did he feel its approach that some time before the end he sent all his papers over to Sir Gilbert Elliot, who kept them under seal until claimed by Mirabeau's executors. In March his illness was evidently gaining on him, to his great grief, because he knew that he alone could yet save France from the distrust of her monarch and the present reforms, and from the foreign interference, which would assuredly bring about catastrophes unparalleled in the history of the world. Every care that science could afford was given by his friend and physician, Cabanis, to whose brochure on his last illness and death the reader may refer. The people kept the street in which he lay quiet; but medical care, the loving solicitude of friends, and the respect of all the people could not save his life. When he could speak no more he wrote with a feeble hand the one word "dormir," and on the 2nd of April 1791 he died.

No man ever so thoroughly used other men's work, and yet made it all seem his own. "Je prends mon bien où je le trouve," is as true of him as of Molière. His first literary work, except the bombastic but eloquent *Essai sur le despotisme* (Neufchâtel, 1775), was a translation of Robert Watson's *Philip II.*, done in Holland with the help of Durival; his *Considérations sur l'ordre de Cincinnatus* (London, 1788) was based on a pamphlet by Aedanus Burke (1743–1802), of South Carolina, who opposed the aristocratic tendencies of the Society of the Cincinnati, and the notes to it were by Target; his financial writings were suggested by the Genevese exile, Clavière. During the Revolution he received yet more help; men were proud to labour for him, and did not murmur because he absorbed all the credit and fame. Etienne Dumont, Clavière, Antoine Adrien Lamourette and Etienne Salomon Reybaz were but a few of the most distinguished of his collaborators. Dumont was a Genevese exile, and an old friend of Romilly's, who willingly prepared for him those famous addresses which Mirabeau used to make the Assembly pass by sudden bursts of eloquent declamation; Clavière helped him in finance, and not only worked out his figures, but even wrote his financial discourses; Lamourette wrote the speeches on the civil constitution of the clergy; Reybaz not only wrote for him his famous speeches on the assignats, the organization of the national guard, and others, which Mirabeau read word for word at the tribune, but even the posthumous speech on succession to the estates of intestates, which Talleyrand read in the Assembly as the last work of his dead friend. Yet neither the gold of the court nor another man's conviction would make Mirabeau say what he did not himself believe, or do what he did not himself think right. He took other men's labour as his due, and impressed their words, of which he had suggested the underlying ideas, with the stamp of his own individuality; his collaborators themselves did not complain—they were but too glad to be of help in the great work of controlling and forwarding the French Revolution through its greatest thinker and orator. As an orator his eloquence has been likened to that of both Bossuet and Vergniaud, but it had neither the polish of the old 17th century bishop nor the flashes of genius of the young Girondin. It was rather parliamentary oratory in which he excelled, and his true compeers are rather Burke and Fox than any French speakers. Personally he had that which is the truest mark of nobility of mind, a power of attracting love and winning faithful friends. (H. M. S.)

Authorities.—The best edition of Mirabeau's works is that published by Blanchard in 1819–1822, in ten volumes, of which the first two contain his *Œuvres oratoires*; from this collection, however, many of his less important works and the *De la monarchie prussienne* are omitted. For details of his life consult Peuchet, *Mirabeau: Mémoires sur sa vie littéraire et privée* (1824); and the *Mémoires biographiques, littéraires et politiques de Mirabeau, écrits par lui-même, par son père, son oncle et son fils adoptif*, which was issued by his adopted son, Lucas de Montigny (8 vols., Paris, 1834–1835). See also Etienne Dumont, *Souvenirs sur Mirabeau* (1832), a work which has been translated into English by Lady E. R. Seymour as *The Great Frenchman and the Little Genevese* (1904); Louise Colet, *La Jeunesse de Mirabeau* (1841); and Alfred Bégis, *Mirabeau, son interdiction judiciaire* (1895). The publication of the *Correspondance entre Mirabeau et le comte de la Marck*, by A. de Bacourt (2 vols., 1851) marks an epoch in our exact knowledge of Mirabeau and his career; some additional letters appeared in the German edition (3 vols., Leipzig, 1851–1852). Other published correspondence is *Lettres de Mirabeau à Chamfort* (1796); *Lettres du comte de Mirabeau à Jacques Mauvillon* (Brunswick, 1792); *Lettres originales de Mirabeau, écrites du donjon de Vincennes, 1777–1780*, published by L. P. Manuel (4 vols., 1792); and, on the same subject, Paul Cottin, *Sophie de Monnier et Mirabeau d'après leur correspondance inédite* (1903); *Lettres à Julie*, edited by D. Meunier and G. Selois (Paris, 1903); *Lettres inédites* (1806), edited by J. F. Vitry. The *Histoire secrète* forms the basis of H. Welschinger's *La Mission secrète de Mirabeau à Berlin* (Paris, 1900). The most useful modern books are Louis and Charles de Loménie, *Les Mirabeau* (5 vols., 1878 and 1889); Alfred Stern, *Das Leben Mirabeaus* (1889). See also E. Rousse, *Mirabeau* (1891) in the Grands Ecrivains Français series; P. Plan, *Un Collaborateur de Mirabeau* (Paris, 1874), treating of Reybaz and throwing infinite light on Mirabeau's mode of work; and H. Reynald, *Mirabeau et la constituante* (1873). On his eloquence and the share his collaborators had in his speeches see F. A. Aulard, *Orateurs de l'assemblée constituante* (1882). For his death see the curious brochure of his physician, Cabanis, *Journal de la maladie et de la mort de Mirabeau* (Paris, 1791, ed. H. Duchenne, Paris, 1890). There is a good sketch summarizing modern opinion by E. Charavay in *La Grande Encyclopédie*. English works include P. F. Willert, *Mirabeau* (1898) in the "Foreign Statesman" series; C. F. Warwick, *Mirabeau and the French Revolution* (1905); W. R. H. Trowbridge, *Mirabeau, the demi-god* (1907); H. E. von Holst, *The French Revolution Tested by Mirabeau's Career* (Chicago, 1894); and F. Fling, *Mirabeau and the French Revolution* (London and New York, 1908). Other works are Victor Hugo, *Étude sur Mirabeau* (1834); Jules Barni, *Mirabeau* (1882); Albert Sorel, "Mirabeau" in *Essais d'histoire et de critique* (1883); G. Leloir, *Mirabeau à Pontarlier* (1886); Ferdinand Schwartz, *Mirabeau und Marie Antoinette* (Basel, 1891); and Alfred Mézières, *Vie de Mirabeau* (1892).

MIRABEAU, VICTOR RIQUETI, Marquis de (1715–1789), French author and political economist, father of the great Mirabeau, was born at Pertuis, near the old château de Mirabeau, on the 4th of October 1715. He was brought up very sternly by his father, and in 1728 joined the army. He took keenly to campaigning, but never rose above the rank of captain, owing to his being unable to get leave at court to buy a regiment. In 1737 he came into the family property on his father's death, and spent some pleasant years till 1743 in literary companionship with duc Clapiers, marquis de Vauvenargues and the poet Lefranc de Pompignan, which might have continued had he not determined to marry—not for money, but for landed estates. The lady whose property he fancied was Marie Geneviève, daughter of a M. de Vassan, a brigadier in the army, and widow of the marquis de Saulveboef, whom he married without previously seeing her on the 21st of April 1743. While in garrison at Bordeaux Mirabeau had made the acquaintance of Montesquieu, and after retiring from the army he wrote his first work, his *Testament Politique* (1747), which demanded for the prosperity of France a return of the French noblesse to their old position in the middle ages. This work was followed in 1750 by a book on the *Utilité des états provenciaux*, which was attributed to Montesquieu himself. In 1756 Mirabeau made his first appearance as a political economist by the publication of his *Ami des hommes ou traité de la population*. This work has been often attributed to the influence, and in part even to the pen, of Quesnay, the founder of the economical school of the physiocrats, but was really written before the marquis had made the acquaintance of the physician of Madame de Pompadour. In 1760 he published his *Théorie de l'impôt*, in which he attacked with all the vehemence of his son the farmers-general of the taxes, who got him imprisoned for eight days at Vincennes, and then exiled to his country estate at Bignon. At Bignon the school of the physiocrats was really established, and the marquis in 1765 bought the *Journal de l'agriculture, du commerce, et des finances*, which became the organ of the school. He was recognized as a leader of political thinkers by Prince Leopold of Tuscany, afterwards emperor, and by Gustavus III. of Sweden, who in 1772 sent him the grand cross of the order of Vasa. But his marriage had not been happy; he had separated from his wife in 1762, and had, he believed, secured her safely in the provinces by a lettre de cachet, when in 1772 she suddenly appeared in Paris, and commenced proceedings for a separation. One of his own daughters had encouraged his wife to take this step. He was determined to keep the case quiet, if possible, for the sake of Mme de Pailly, a Swiss lady whom he had loved since 1756. But his wife would not let him rest; her plea was rejected in 1777, but she renewed her suit, and, though the great Mirabeau had pleaded his father's case, was successful in 1781. This trial quite broke the health of the marquis, as well as his fortune; he sold his estate at Bignon, and hired a house at Argenteuil, where he lived quietly till his death on the 11th of July 1789.

The marquis's younger brother, Jean Antoine Riqueti, "the bailli" (d. 1794), served with distinction in the navy, but his brusque manners made success at court impossible. In 1763 he became general of the galleys of Malta. In 1767 he returned to France and took charge of the château de Mirabeau, helping the marquis in his disastrous lawsuits.

See Louis de Loménie's *Les Mirabeau* (2 vols., 1879). MIRACLE (Lat. *miraculum*, from *mirari*, to wonder), anything wonderful, beyond human power, and deviating from the common action of the laws of nature, a supernatural event. The term is particularly associated with the supernatural factors in Christianity. To the Lat. *miraculum* correspond Gr. *τέρας* in the New Testament, and Heb. פֶּלֶא (Exod. xv. 11; Dan. xii. 6) in the Old Testament. Other terms used in the New Testament are *δύναμις* "with reference to the power residing in the miracle worker" (cf. גבורה Deut. iii. 24 and בריאה Num. xvi. 30), and *σημεῖον* "with reference to the character or claims of which it was the witness and guarantee" (cf. אות Exod. iv. 8); that the power is assumed to be from God is shown by the phrases *πνεύματι θεοῦ* (Matt. xii. 28; cf. Luke iv. 18) and *δακτύλῳ θεοῦ* (Luke xi. 20).

While Augustine describes miracles as "contra naturam quae nobis est nota," Aquinas without qualification defines them as "praeter naturam," "supra et contra naturam." Löscher affirms in regard to miracles that "solus Deus potest tum supra naturae vires tum contra naturae leges agere"; and Buddaeus argues that in them a "suspensio legum naturae" is followed by a *restitutio*. Against the common view that miracles can attest the truth of a divine revelation Gerhard maintained that "per miracula non possunt probari oracula"; and Höpfner returns to the qualified position of Augustine when he describes them as "praeter et supra naturae ordinem." The two conceptions, once common in the Christian church, that on the one hand miracles involved an interference with the forces and a suspension of the laws of nature, and that, on the other hand, as this could be effected only by divine power, they served as credentials of a divine revelation, are now generally abandoned. As regards the first point, it is now generally held that miracles are exceptions to the order of nature as known in our common experience; and as regards the second, that miracles are constituent elements in the divine revelation, deeds which display the divine character and purpose; but they are *signs* and not merely *seals* of truth. Some of the theories regarding miracles which have been formulated may be mentioned. Bonnet, Euler, Haller, Schmid and others "suppose miracles to be already implanted in nature. The miraculous germs always exist alongside other germs in a sort of sheath, like hidden springs in a machine, and emerge into the light when their time comes." Similar is the view of Paracelsus and Jerome Cardan, who "suppose a twofold world, existing one in the other; beside or behind the visible is an inner, ideal world, which breaks through in particular spots" (Dorner's *System of Christian Doctrine*, ii. 155, 156). The 8th duke of Argyll (*Reign of Law*) maintains that "miracles may be wrought by the selection and use of laws of which man knows and can know nothing, and which, if he did know, he could not employ." These theories endeavour to discover the means by which the exceptional occurrence is brought about; but the explanation is merely hypothetical, and we are not helped in conceiving the mode of the divine activity in the working of miracles. The important consideration from the religious standpoint is that God's activity should be fully recognized.

An attempt has been made to discover a natural law which will explain some at least of the miracles of Jesus. "In one respect alone," says Matthew Arnold, "have the miracles recorded by the evangelists a more real ground than the mass of miracles of which we have the relation. Medical science has never gauged, perhaps never enough set itself to gauge the intimate connexion between moral fault and disease. To what extent or in how many cases what is called illness is due to moral springs having been used amiss, whether by being over-used, or by not being used sufficiently, we hardly at all know, and we too little inquire. Certainly it is due to this very much more than we commonly think, and the more it is due to this the more do moral therapeutics rise in possibility and importance" (*Literature and Dogma*, pp. 143–144). The moral therapeutics consists in the influence of a powerful will over others. Harnack accepts this view. "We see that a firm will and a convinced faith act even on the bodily life and cause appearances which appeal to us as miracles. Who has hitherto here with certainty measured the realm of the possible and the real? Nobody. Who can say how far the influences of one soul on another soul and of the soul on the body reach? Nobody. Who can still affirm that all which in this realm appears as striking rests only on deception and error? Certainly no miracles occur, but there is enough of the wonderful and the inexplicable" (*Das Wesen des Christentums*, p. 18). As regards the theory, it may be pointed out: (1) that the *nature* or *cosmical* miracles—feeding of the five thousand, stilling of the storm, withering of the fig-tree—are as well-attested as the miracles of healing; (2) that many of the diseases, the cure of which is reported, are of a kind with which *moral therapeutics* could not effect anything;[1] (3) that Christ's own insight regarding the power by which He wrought His works is directly challenged by this explanation, for He never failed to ascribe His power to the Father dwelling in Him.

The divine agency is recognized as combining and controlling, but not as producing, in the teleological notion of miracles. "In miracle no new powers, instituted or stimulated by God's creative action, are at work, but merely the general order of nature"; but "the manifold physical and spiritual powers in actual existence so blend together as to produce a startling result" (Dorner's *System of Christian Doctrine*, ii. 157). While we cannot deny, we have no ground for affirming the truth of this theory. Whether God's action is creative, or only selective and directive in miracles, is beyond our knowledge; we at least do not know the powers exercised, whether new or old.

An attempt is made to get rid of the distinctive nature of miracle when the exceptionalness of the events so regarded is reduced to a *new subjective mode* of regarding natural phenomena. H. E. G. Paulus dismisses the miracles as "exaggerations or misapprehensions of quite ordinary events." A. Ritschl has been unjustly charged with this treatment of miracles. But what he emphasizes is on the one hand the close connexion between the conception of miracles and the belief in divine providence, and on the other the compatibility between miracles and the order of nature. He declines to regard miracles as divine action contrary to the laws of nature. So for Schleiermacher "miracle is neither explicable from nature alone, nor entirely alien to it." What both Ritschl and Schleiermacher insist on is that the belief in miracles is inseparable from the belief in God, and in God as immanent in nature, not only directing and controlling its existent forces, but also as initiating new stages consistent with the old in its progressive development.

We may accept Dorner's definition as adequate and satisfactory. "Miracles are sensuously cognizable events, not comprehensible on the ground of the causality of nature as such, but essentially on the ground of God's free action alone. Such facts find their possibility in the constitution of nature and God's living relation to it, their necessity in the aim of revelation, which they subserve" (p. 161). By the first clause, inward moral and religious changes due to the operation of the Spirit of God in man are excluded, and rightly so (see INSPIRATION). The negative aspect is presented in the second clause. This is prominent in J. S. Mill's definition of miracles: "to constitute a miracle, a phenomenon must take place without having been preceded by any antecedent phenomenal conditions sufficient again to reproduce it. . . . The test of a miracle is, were there present in the case such external conditions, such second causes we may call them, that wherever these conditions or causes reappear the event will be reproduced. If there were, it is not a miracle; if there were not, it is" (*Essays*, p. 224). The positive aspect is presented in the third clause. When the existence of God is denied (atheism), or His nature is declared unknowable (agnosticism), or He is identified with nature itself (pantheism), or He is so distinguished from the world that His free action is excluded from the course of nature (deism), miracle is necessarily denied. Thus Spinoza, identifying God and nature, declares "nothing happens in nature which is in contradiction with its universal laws." The deists, compelled by their view of the relation of God to nature to regard miracles as interventions, disposed of the miracles of the Bible either as "mistaken allegory" or even as conscious fraud on the part of the narrators. It is only the theistic view of God as personal power—that is as free-will ever present and ever active in the world, which leaves room for miracles.

The *possibility* of miracles is often confidently denied. "We are of the unalterable conviction," says Harnack, "that what happens in time and space is subject to the universal laws of movement; that accordingly there cannot be any miracles in this sense, *i.e.* as interruptions of the continuity of nature" (*Das Wesen des Christentums*, p. 17). Huxley expresses himself much more cautiously, as he recognizes that we do not know the continuity of nature so thoroughly as to be able to declare that this or that event is necessarily an interruption of it. "If a dead man did come to life, the fact would be evidence, not that any law of nature had been violated, but that these laws, even when they express the results of a very long and uniform experience, are necessarily based on incomplete knowledge, and are to be held only on grounds of more or less justifiable expectation" (*Hume*, p. 135).

Lotze has shown how the possibility of miracle can be conceived. "The whole course of nature becomes intelligible only by supposing the co-working of God, who alone carries forward the reciprocal action of the different parts of the world. But that view which admits a life of God that is not benumbed in an unchangeable sameness will be able to understand his eternal co-working as a variable quantity, the transforming influence of which comes forth at particular moments and attests that the course of nature is not shut up within itself. And this being the case, the complete conditioning causes of the miracle will be found in God and nature together, and in that eternal action and reaction between them which perhaps, although not ordered simply according to general laws, is not void of regulative principles. This vital, as opposed to a mechanical, constitution of nature, together with the conceptions of nature as not complete in itself—as if it were dissevered from the divine energy—shows how a miracle may take place without any disturbance elsewhere of the constancy of nature, all whose forces are affected sympathetically, with the consequence that its orderly movement goes on unhindered" (*Mikrokosmos*, iii. 364).

The mode of the divine working in nature is in another passage more clearly defined.

"The closed and hard circle of mechanical necessity is not immediately accessible to the miracle-working fiat, nor does it need to be; but the inner nature of that which obeys its laws is not determined by it but by the meaning of the world. This is the open place on which a power that commands in the name of this meaning can exert its influence; and if under this command the inner condition of the elements, the magnitudes of their relation and their opposition to each other, become altered, the necessity of the mechanical cause of the world must unfold this new state into a miraculous appearance, not through suspension but through strict maintenance of its general laws" (*op. cit.* ii. 54).

If we conceive God as personal, and His will as related to the course of nature analogously to the relation of the human will to the human body, then the laws of nature may be regarded as habits of the divine activity, and miracles as unusual acts which, while consistent with the divine character, mark a new stage in the fulfilment of the purpose of God.

The doctrine of Evolution, instead of increasing the difficulty of conceiving the possibility of miracle, decreases it; for it presents to us the universe as an uncompleted process, and one in which there is no absolute continuity on the phenomenal side; for life and mind are inexplicable by their physical antecedents, and there is not only room for, but need of, the divine initiative, a creative as well as conservative co-operation of God with nature. Such an absolute continuity is sometimes assumed without warrant; but Descartes already recognized that the world was no continuous process, "Tria mirabilia fecit Dominus; res ex nihilo, liberum arbitrium et hominem Deum." That life cannot be explained by force is recognized by Sir Oliver Lodge. "Life may be something not only ultra-terrestrial, but even immaterial, something outside our present categories of matter and energy; as real as they are, but different, and utilizing them for its own purpose" (*Life and Matter*, p. 198). The theory of *psychophysical parallelism* recognizes that while there is a correspondence between mental and material phenomena, changes in the mind and changes in the brain, the former cannot be explained by the latter, as the transition from the one to the other is unthinkable. William James distinguishes the *transmissive* function of the brain from the *productive* in relation to thought, and admits only the former, and not the latter (*Human Immortality*, p. 32). Thus as life is transcendent and yet immanent in body, and mind in brain, and both utilize their organs, so God, transcendent and immanent, uses the course of nature for His own ends; and the emergence both of life and mind in that course of nature evidences such a divine initiative as is assumed in the recognition of the possibility of miracles. For such an initiative there must be adequate reason; it must be prepared for in the previous process, and it must be necessary to further progress.

---

[1] See also R. J. Ryle, "The Neurotic Theory of the Miracles of Healing," *Hibbert Journal*, v. 586.

The proof of the possibility of miracle leads us inevitably to the inquiry regarding the *necessity* of miracle. The necessity of miracles is displayed in their connexion with the divine revelation; but this connexion may be conceived in two ways. The miracles may be regarded as the *credentials* of the agents of divine revelation. "It is an acknowledged historical fact," says Butler, "that Christianity offered itself to the world, and demanded to be received, upon the allegation—*i.e.* as unbelievers would speak—upon the pretence of miracles, publicly wrought to attest the truth of it, in such an age; and that it was actually received by great numbers in that very age, and upon the professed belief of the reality of miracles" (*Analogy*, part ii. ch. vii.). This view is now generally abandoned; for it is recognized that acts of superhuman power, even if established by adequate historical evidence, do not necessarily certify their divine origin. Their moral quality must correspond with the character of God; and they must be connected with teaching which to reason and conscience approves itself divine. "Miracula sine doctrina nihil valent" is the principle now generally recognized. The miracle and the doctrine mutually illuminate one another. "Les miracles discernent la doctrine, et la doctrine discerne les miracles" (Pascal's *Pensées des miracles*). Accordingly, the *credentials* must also be *constituents* of the revelation. Of the miracles of Jesus, Bushnell says, "The character of Jesus is ever shining with and through them, in clear self-evidence leaving them never to stand as raw wonders only of might, but covering them with glory as tokens of a heavenly love, and acts that only suit the proportions of His personal greatness and majesty" (*Nature and the Supernatural*, p. 364). If it be asked why the character may not be displayed in ordinary acts instead of miracles, the answer may be given, "Miracle is the certificate of identity between the Lord of Nature and the Lord of Conscience—the proof that He is really a moral being who subordinates physical to moral interests" (Lidden's *Elements of Religion*, p. 73). As God is the Saviour, and the chief end of the revelation is redemption, it is fitting that the miracles should be acts of divine deliverance from physical evil. This congruity of the miracle with divine truth and grace is the answer to Matthew Arnold's taunt about turning a pen into a pen-wiper or Huxley's about a centaur trotting down Regent Street. The miracles of Jesus—the relief of need, the removal of suffering, the recovery of health and strength—reveal in outward events the essential features of His divine mission. The divine wisdom and goodness are revealed in the course of nature, but also obscured by it. The existence of physical evil, and still more of moral evil, forbids the assumption without qualification that the real is the rational. God in nature as well as history is fulfilling a redemptive as well as perfective purpose, of which these miracles are appropriate signs. It is an unwarranted idealism and optimism which finds the course of nature so wise and so good that any change in it must be regarded as incredible. On the problem of evil and sin it is impossible here to enter; but this must be insisted on, that the miracles of Jesus at least express divine benevolence just under those conditions in which the course of nature obscures it, and are therefore, proper elements in a revelation of grace, of which nature cannot give any evidence.

Having discussed the possibility and necessity of miracles for the divine revelation, we must now consider whether there is sufficient historical evidence for their occurrence. Hume maintains that no evidence, such as is available, can make a miracle credible. Mill states the position with due care. "The question can be stated fairly as depending on a balance of evidence, a certain amount of positive evidence in favour of miracles, and a negative presumption from the general course of human experience against them" (*Essays on Religion*, p. 221). The existence of "a certain amount of positive evidence in favour of miracles" forbids the sweeping statement that miracles are "contrary to experience." The phrase itself is, as Paley has pointed out, ambiguous. If it means *all* experience it assumes the point to be proved; if it means only *common* experience then it simply asserts that the miracle is unusual—a truism. The *probability* of miracles depends on the conception we have of the free relation of God to nature, and of nature as the adequate organ for the fulfilment of God's purposes. If we believe in a divine revelation and redemption, transcending the course of nature, the miracles as signs of that divine purpose will not seem improbable.

For the Christian Church the miracles of Jesus are of primary importance; and the evidence—external and internal—in their favour may be said to be sufficient to justify belief. The Gospels assumed their present form between A.D. 60 and 90. Their representation of the moral character, the religious consciousness, the teaching of Jesus, inspires confidence. The narratives of miracles are woven into the very texture of this representation. In these acts Jesus reveals Himself as Saviour. "The Jesus Christ presented to us in the New Testament would become a very different person if the miracles were removed" (Temple's *Relations between Religion and Science*). In His sinless perfection and filial relation to God He is unique, and His works are congruous with His Person. Of the supreme miracle of His resurrection there is earlier evidence than of any of the others (1 Cor. xv. 3–7, before A.D. 58). His conquest of death is most frequently appealed to in the apostolic teaching. The Christian Church would never have come into existence without faith in the Risen Lord. The proof of the supernaturalness of His Person sets the seal to the credibility of His supernatural works. In Christ, however, was the fulfilment of law and prophecy. This close connexion invests the antecedent revelation in some degree with the supernaturalness of His Person: at least, we are prepared to entertain without prejudice any evidence that may be presented in the Old Testament. That this evidence is not as good as that for the miracles of Jesus must be conceded, as much of it is of much later date than the events recorded. The miracles connected with the beginnings of the national history—the period of the Exodus—appear on closer inspection to have been ordinarily natural phenomena, to which a supernatural character was given by their connexion with the prophetic word of Moses. The miracles recorded of Elijah and Elisha lie somewhat apart from the main currents of the history, the narratives themselves are distinct from the historical works in which they have been incorporated, and the character of some of the actions raises serious doubts and difficulties. In some cases suspense of judgment seems necessary even from the standpoint of Christian faith. The supernatural element that is prominent in the Old Testament is God's providential guidance and guardianship of His people, and His teaching and training of them by His prophets. The Apostolic miracles, to which the New Testament bears evidence, were wrought in the power of Christ, and were evidences to His church and to the world of His continued presence. When the Church had established itself in the world, and possessed in its moral and religious fruits evidence of its claims, these outward signs appear gradually to have ceased, although attempts were made to perpetuate them. It is true that in Roman Catholicism, in medieval as in modern times, the working of miracles has been ascribed to its saints; but the character of most of these miracles is such as to lack the *a priori probability* which has been claimed for the Scripture miracles on account of their connexion and congruity with the divine revelation. The *a posteriori evidence* as regards both its moral and religious quality and its date is altogether inferior to the evidence of the Gospels. Further, these records are imitative. As Christ and the apostles worked miracles, it is assumed that those who in the Church were distinguished for their sanctity would also work miracles; and there can be little doubt that the wish was often father to the thought. There may be cases which cannot be explained in this way; but "whatever may be thought about them, it is plain that even if these and their like are really to be traced to the intervention of the divine mercy which loves to reward a simple faith (and it does not seem to us that the evidence is sufficient to establish such a conclusion), yet they do not serve as vehicles of revelation as the miracles of the Gospel did" (H. J. Bernard in Hastings's *Bible Dictionary*, iii. 395). (A. E. G.*)

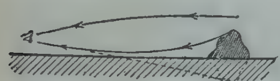
MIRA DE AMESCUA, ANTONIO (1578?–1636?), Spanish dramatist, was born at Guadix (Granada) about 1578. He is said, but doubtfully, to have been the illegitimate son of one Juana Perez; he took orders, obtained a canonry at Guadix, and settled at Madrid early in the 17th century. He is mentioned as a prominent dramatist in Rojas Villandrando's *Loa* (1603), which was written several years before it was published. In 1610, being then arch-dean of Guadix, he accompanied the count de Lemos to Naples, and on his return to Spain was appointed (1619) chaplain to the cardinal Infante Ferdinand of Austria; he is referred to as still alive in Montalbán's *Para todos* (1632), and he collaborated with Montalbán and Calderón in *Polifemo y Circe*, printed in 1634. The date of his death is not known. Mira de Amescua's plays are dispersed in various printed collections, and the absence of a satisfactory edition has prevented his due recognition. He has an evenness of execution which indicates an artistic conscience uncommon in Spanish playwrights; he resisted the temptation to write too much, and he unites a virile dignity of expression to impressive conception of character.

Two of his plays—*La Adversa fortuna de Don Bernado de Cabrera* and *El ejemplo mayor de la desdicha*—are respectively the sources of Rotrou's *Don Bernardo de la Cabrère* and *Belisaire*; Moreto's *Caer para levantar* is simply a recast of Mira's *El Esclavo del demonio*, a celebrated drama which clearly influenced Calderón when composing *La Devoción de la cruz*; and there is manifestly a close relation between Mira's *La Rueda de la fortuna* on the one hand and Corneille's *Héraclius* and Calderón's *En esta vida todo es verdad y todo es mentira*. A few of Mira de Amescua's plays are reprinted in the *Biblioteca de autores españoles*, vol. xlv.

MIRAGE (a French word, from *mirer*, to look at, *se mirer*, to be reflected), an optical illusion due to variations in the refractive index of the atmosphere. It embraces the phenomena of the visionary appearance of lakes in arid deserts, the images of ships and icebergs, frequently seen as if inverted and suspended in the atmosphere in the Polar Regions, the *Fata Morgana*, and "looming" as witnessed in mists or fogs.

In the article Refraction it is shown that a ray of light traversing a homogeneous medium is deviated from its rectilinear path when it enters a medium of different refractive index; it is therefore readily seen that the path of a ray through continuously varying media is necessarily curvilinear, being compounded of an infinite number of infinitesimally small rectilinear deviations. Our atmosphere is a medium of continuously varying refractive index. Meteorological optical phenomena, due to variations in the refractive index of the atmosphere, may be divided into groups: (1) those due to the permanent or normal variation experienced as one ascends in the atmosphere, and (2) those due to sporadic variations occasioned by irregular heating. The first variation must be taken into account in correcting geodetic observations of heights and astronomical observations of the heavenly bodies; it also has a considerable bearing on the phenomena of the twilight and the afterglow (see Refraction: § *Astronomical*; and Twilight). The second (or temperature) variation gives rise to phenomena which we proceed to discuss.

A common type of mirage is the appearance of an isolated lake frequently seen in hot sandy deserts, as in the Sahara, Turkestan, &c. The explanation is as follows: The sand, being abnormally heated by the solar rays, causes the neighbouring air to expand, consequently its density, and therefore its refractive index, is diminished, and attains a minimum value in the lowest layers. It increases as we ascend and reaches a maximum at a certain height, and then decreases according to the normal variation. Any object viewed across such an area is seen by two sets of rays: one set passing near the earth and assuming a curved path convex to the horizon, the second set more remote from the earth and concave to the horizon. The object thus appears double, an image being seen mirrored in the sand. The sky appears as a shining lake; mountains or palms may be similarly reflected, but it is to be noted that the images are inverted (see fig.). Similar atmospheric conditions sometimes prevail in the air over large bodies of water on cold autumn mornings. These phenomena have been experimentally realized by R. W. Wood (*Phil. Mag.*, 1899, vol. xlvii.), who viewed objects over a series of heated slate slabs.



Another type of mirage, frequently observed at sea in the northern latitudes, is presented in the appearance of ships and icebergs as if inverted and suspended in the clouds. This is due to a stratum of hot air at some distance above the sea level, the rays of light near the horizon being practically horizontal, while those at greater elevations are fairly concave. It may happen that the change in density is so great that only the upper rays reach the eye; we are then met with the curious illusion of seeing inverted ships in the clouds, although nothing is visible on the ocean.

The *Fata Morgana*, frequently seen in the Straits of Messina, consists of an apparent vertical elongation of an object situated on the opposite shore. The distribution of density is similar to that attending a desert mirage, but the transition is not so abrupt. The object is really viewed through a horizontally stratified medium consisting of a central sheet of maximum refractive index, over- and under-laid by sheets of decreasing refractive power. The system consequently acts as a continuous lens, magnifying the object in a vertical direction.

If, in addition to this horizontal stratification, the atmosphere varies similarly in vertical planes, then the object would be magnified both horizontally and vertically. These conditions sometimes prevail in misty or foggy weather, more particularly at sea, and thus give rise to the phenomena known as "looming." A famous example is the *Brockengespenst* or "spectre of the Brocken." The chromatic halos which frequently encircle these images are due to diffraction. (See Corona.)

It is interesting to note that lenses formed on non-homogeneous material, having the maximum refractive index along the central axis, have been prepared, and reproduce the effects caused by abnormal distribution of the density of the atmosphere.

The mathematical investigation of this subject was worked out by Gaspard Monge. For this aspect and further details, both descriptive and experimental, see J. Pernter, *Meteorologische Optik* (1906); E. Mascart, *Traité d'optique* (1899–1903); R. W. Wood, *Physical Optics* (1905); R. S. Heath, *Geometrical Optics*.

MIRAJ, a native state of India, in the Deccan division of Bombay, forming part of the southern Mahratta Jagirs. Since 1820 it has been subdivided between a senior and a junior branch. The territory of both is widely scattered among other native states and British districts. Area of the senior branch, 339 sq. m.; pop. (1901), 81,467; revenue £23,000; tribute £800. Area of the junior branch, 211 sq. m.; pop. (1901), 35,806; revenue £27,000, tribute £400. The chiefs are Brahmans of the Patwardhan family. The town of Miraj, at which the chief of the senior branch resides, is situated near the river Kistna; it is a junction of the Southern Mahratta railway for the branch to Kolhapur. Pop. (1901), 18,425. The chief of the junior branch has his residence at Bhudgaon (pop. 3591).

MIRAMON, MIGUEL (1832–1867), Mexican soldier of French extraction, was born in the city of Mexico, on the 29th of September 1832, and shot with the Emperor Maximilian at Queretaro on the 19th of June 1867. While still a student he helped to defend the military academy at Chapultepec against the forces of the United States; and, entering the army in 1852, he rapidly came to the front during the civil wars. It was largely due to Miramon's support of the ecclesiastical party against Alvarez and Comonfort that Zuloaga was raised to the presidency; and in 1859 he was called to succeed him in that office. Decisively beaten by the Liberals in 1860, he spent some time in Europe advocating foreign intervention in Mexican affairs; and returned as a partisan of Maximilian. His ability as a soldier was shown by his double defence of Puebla in 1856.

MIRANDA, FRANCESCO (*c.* 1754–1816), Spanish-American soldier and adventurer, was born at Carácas, Venezuela, about 1754. He entered the army, and served with the French in the American War of Independence. The success of that war inspired him with a belief that the independence of Spanish America would increase its prosperity. He began to scheme a revolution, but was discovered and had only just time to escape to the United States. Thence he went to England, where he was introduced to Pitt, but chiefly lived with the leading members of the opposition—Fox, Sheridan and Romilly. Finding no help, he travelled through Austria and Turkey to Russia, where he was warmly received, but was dismissed with rich presents, at the demand of the Spanish ambassador, backed up by France. The news of the dispute between England and Spain about Nootka Sound in 1790 recalled him to England, where he saw a good deal of Pitt, but the peaceful arrangement of the dispute again destroyed his hopes. In April 1792 he went to Paris, with introductions to Pétion and the leading Girondists, hoping for aid in South America. France had too much to do to help others; but Miranda's friends sent him to the front as general of brigade. He distinguished himself under Dumouriez, was entrusted in February 1793 with the siege of Maestricht, and commanded the left wing of the French army at the disastrous battle of Neerwinden. Although he had given notice of Dumouriez's treachery, he was put on his trial on the 12th of May, unanimously acquitted, but again imprisoned, and not released till after the 9th Thermidor. He was sentenced to be deported after the struggle of Vendémiaire, yet he continued in Paris till the *coup d'état* of Fructidor caused him to take refuge in England. He now found Pitt and Dundas ready to listen, but, as neither of them would or could give him substantial help, he went to the United States, where President Adams only gave him fair words. Addington might have done something for him but for the peace of Amiens in 1802. Though in no way amnestied, he returned to Paris, but was expelled by the First Consul, who was eager to be on good terms with Spain. Disappointed in England and the United States, he decided to make an attempt at his own expense. Aided by two American citizens, Colonel W. S. Smith and Mr S. G. Ogden, he equipped the "Leander," in 1806, and with the help of the English admiral Sir A. Cochrane made a landing near Carácas, and proclaimed the Colombian republic. He had some success, but a false report of peace between France and England caused the English admiral to withdraw his support. At last, in 1810, the events in Spain which brought about the Peninsular War had divided the authorities in Spanish America, some of whom declared for Joseph Bonaparte, others for Ferdinand VII., others for Charles IV., and Miranda again landed, and got a large party together who declared a republic both in Venezuela and New Granada or Colombia. But Miranda's desire—that all the South American colonies should form a federal republic—awoke the selfishness of provincial administrations, and the cause was believed to be hateful to heaven owing to a great earthquake on the 26th of March 1812. The count of Monte Verde, the Bourbon governor, had little difficulty in defeating Miranda, and on the 26th of July the general capitulated on condition that he should be deported to the United States. The condition was not observed; Miranda was moved from dungeon to dungeon, and died on the 14th of July 1816 at Cadiz.

There are allusions to Miranda's early life in nearly all memoirs of the time, but they are not generally very accurate. For his trial see Buchez et Roux, *Histoire parlementaire*, xxvii. 26–70. For his later life see J. Biggs, *History of Miranda's Attempt in South America* (London, 1809); and Veggasi, *Revolucion de la Colombia.* Prof. William S. Robertson has recently devoted considerable research in the Spanish archives and elsewhere to Miranda, his monograph on *F. de M. and the revolutionizing of Spanish America* being awarded a prize of the American Historical Association in 1908. See also Marqués de Rojas, *El General Miranda* (Paris, 1884), and his *Miranda dans la révolution française* (Carácas, 1889); and R. Becerra, *Ensayo historico documentado de la vida de Don F. de M.* (Carácas, 1896).

MIRANDE, a town of south-western France, capital of an arrondissement in the department of Gers, on the left bank of the Grande Baise, 17 m. S.S.W. of Auch by the Southern railway. Pop. (1906), 2368. Mirande is laid out on the uniform plan typical of the *bastide.* Its church, built at the beginning of the 15th century, is chiefly remarkable for its porch which bestrides the Rue de l'Évêché and is surmounted by two flying buttresses supporting a belfry of Flemish appearance. The remains of ramparts are still to be seen and the principal street is bordered by ancient arcades. The town has a sub-prefecture and a tribunal of first instance. The trade is in live-stock and agricultural products. Tanning and wood-turning are carried on.

Mirande was founded in 1286 by the monks of Berdones and the seneschal of Toulouse acting on behalf of Philip IV. During the 14th century it was the capital of the counts of Astarac.

MIRANDOLA, a town of Emilia, Italy, in the province of Modena, 19½ m. N. by E. of it by rail, 59 ft. above sea-level. Pop. (1901), 15,162. The Palazzo del Commune is a 15th-century edifice of Gothic style. The castle of the Pico family, who held the town from the 14th century to 1710, when the last member was deprived of his dominions by Joseph I. of Austria, is almost entirely destroyed. The height of the fortunes of this family was from about 1450 to 1550, Giovanni (b. 1463, d. 1494) being its ablest and most learned member (see Pico). The cathedral, dating from the end of the 16th century, has been restored. S. Francesco is a fine Gothic church.

MIRANZAI VALLEY, or Hangu, a mountain valley on the Kohat border of the North-West Frontier Province of India. Miranzai comprises two valleys draining S.W. into the Kunam and N.E. into the Kohat Toi. It is thus divided into upper and lower Miranzai, and extends from Thal to Raisan, and from the Zaimukht and Orakzai hills to those of the Khattaks. Its length is about 40 m., and its breadth varies from 3 to 7 m. Area, 546 sq. m.; pop. (1901), 43,901. The portion of Miranzai east of Hangu village consists of numerous small and well-cultivated valleys, in which orchard trees flourish abundantly. To the west of Hangu, including the whole of Upper Miranzai, the country is a broad, open, breezy valley. The plain is bare of trees, but the hills are generally covered with scrub. The country is full of ravines towards Thal. The wealth of the inhabitants consists principally in cattle, goats and sheep; of these the cows are of a lean and dwarf breed, and give but little milk. Miranzai forms the meeting place of many different tribes; but its chief inhabitants are the Bangash and Orakzais. Disturbances have necessitated British expeditions in 1851, 1855, and twice in 1891.

MIRBEAU, OCTAVE HENRI MARIE (1850–), French dramatist and journalist, was born at Trevières (Calvados) on the 16th of February 1850. He was educated in a Jesuit school at Vannes, and studied law in Paris. He began his journalistic career as dramatic critic of the Bonapartist paper, *L'Ordre.* For a short time before 1877 he was *sous-préfet* and then *préfet* of Saint-Girons, but from that time he devoted himself to literature. He was one of the earliest defenders of the Impressionist painters. His witty articles in the anti-republican papers, and his attacks on established reputations, involved him in more than one duel. He gradually developed extreme individualist views. In 1890 he began to write for the *Révolte,* but his anarchist sympathies were definitely checked by the murder of President Carnot in 1894. He was one of the early and consistent defenders of Captain Alfred Dreyfus. He married in 1887 the actress Alice Regnault. His first novel, *Jean Marcellin* (1885), attracted little attention, but he made his mark as a *conteur* with a series of tales of the Norman peasantry, *Lettres de ma chaumière* (1886). *Le Calvaire* (1887), a chapter of which on the defeat of 1870 aroused much discussion, was followed by *L'Abbé Jules* (1888), the story of a mad priest; by *Sebastien Roch* (1890), a bitter picture of the Jesuit school in which his own early years were spent; *Le Jardin des supplices* (1899), a Chinese story; *Les Mémoires d'une femme de chambre* (1901); and *Les Vingt-et-un jours d'un neurasthénique* (1902). In 1897 his five-act piece, *Les Mauvais Bergers,* was played at the Renaissance by Sarah Bernhardt, and he followed this up with *Les Affaires sont les affaires* (Théâtre Français, 1903), which was adapted by Sydney Grundy for Sir H. Beerbohm Tree in 1905. Some of his short pieces are collected as *Farces et moralités* (1904).

MIRFIELD, an urban district in the Morley parliamentary division of the West Riding of Yorkshire, England, 3 m. S.W. of Dewsbury, on the Lancashire & Yorkshire and London & North-Western railways. Pop. (1901), 11,341. The church of St Mary was completed in 1874, from designs of Sir Gilbert Scott. The tower of the ancient church remains. The large industrial population is employed in woollen, cotton, carpet and blanket manufactures, and in the numerous collieries in the vicinity.

MIRKHOND (1433–1498). Mohammed bin Khāwandshāh bin Mahmūd, commonly called Mīrkhwānd or Mīrkhāwand, more familiar to Europeans under the name of Mirkhond, was born in 1433, the son of a very pious and learned man who, although belonging to an old Bokhara family of Sayyids, or direct descendants of the Prophet, lived and died in Balkh. From his early youth he applied himself to historical studies and literature in general. In Herāt, where he spent the greater part of his life, he gained the favour of that famous patron of letters, Mīr 'Alīshīr (1440–1501), who served his old schoolfellow, the reigning sultan Husain (who as the last of the Tīmūrides in Persia ascended the throne of Herāt in 1468), first as keeper of the seal, afterwards as governor of Jurjān. At the request of

Mīr ʿAlīshīr, himself a distinguished statesman and writer, Mirkhond began about 1474, in the quiet convent of Khilāsīyah, which his patron had founded in Herāt as a house of retreat for literary men of merit, his great work on universal history, *Rauẓat-ussafā fi sīrat-ulanbiā walmulūk walkhulafā* or *Garden of Purity on the Biography of Prophets, Kings and Caliphs*. He made no attempt at a critical examination of historical traditions, and wrote in a flowery and often bombastic style, but in spite of this drawback, Mirkhond's *Rauẓat* remains one of the most marvellous achievements in literature. It comprises seven large volumes and a geographical appendix; but the seventh volume, the history of the sultan Husain (1438–1505), together with a short account of some later events down to 1523, cannot have been written by Mirkhond himself, who died in 1498. He may have compiled the preface, but the main portion of this volume is probably the work of his grandson, the historian Khwāndamīr (1475–1534), to whom also a part of the appendix must be ascribed.

For accounts of Mirkhond's life see De Sacy's "Notice sur Mirkhond" in his *Mémoires sur diverses antiquités de la Perse* (Paris, 1793); Jourdain's "Notice de l'histoire universelle de Mirkhond" in the *Notices et extraits*, vol. ix. (Paris, 1812); Elliot, *History of India*, iv. 127 seq.; Morley, *Descriptive Catalogue* (London, 1854), p. 30 seq.; Rieu, *Cat. of Persian MSS. of the Brit. Mus.* (vol. i. London, 1879), p. 87 seq. Besides the lithographed editions of the whole work in folio (Bombay, 1853, and Teheran, 1852–1856) and a Turkish version (Constantinople, 1842), the following portions of Mirkhond's history have been published by European Orientalists: *Early Kings of Persia*, by D. Shea (London, 1832) (Oriental Translation Fund); *L'Histoire de la dynastie des Sassanides*, by S. de Sacy (in the above-mentioned *Mémoires*); *Histoire des Sassanides* (*texte Persan*), by Jaubert (Paris, 1843); *Historia priorum regum Persarum*, Persian and Latin, by Jenish (Vienna, 1782); *Mirchondi historia Taheridarum*, Persian and Latin, by Mitscherlik (Göttingen, 1814, 2nd ed., Berlin, 1819); *Historia Samanidarum*, Persian and Latin, by Wilken (Göttingen, 1808); *Histoire des Samanides*, translated by Defrémery (Paris, 1845); *Historia Ghaznevidarum*, Persian and Latin, by Wilken (Berlin, 1832); *Geschichte der Sultane aus dem Geschlechte Bujeh*, Persian and German, by Wilken (Berlin, 1835); followed by Erdmann's *Erläuterung und Ergänzung* (Kazan, 1836); *Historia Seldschuckidarum*, ed. Vullers (Giessen, 1837); and a German trans. by the same; *Histoire des Sultans du Kharezm*, in Persian, by Defrémery (Paris, 1842); *History of the Atabeks of Syria and Persia*, in Persian, by W. Morley (London, 1848); *Historia Ghuridarum*, Persian and Latin, by Mitscherlik (Frankfort, 1818); *Histoire des Sultans Ghurides*, trans. into French by Defrémery (Paris, 1844); *Vie de Djenghiz-Khan*, in Persian, by Jaubert (Paris, 1841) (see also extracts from the same 5th vol. in French trans. by Langlès in vol. vi. of *Notices et extraits*, Paris, 1799, p. 192 seq.), and by Hammer in *Sur les origines russes*, St Petersburg, 1825, p. 52 seq.); "Tīmūr's Expedition against Tuktamish Khān," Persian and French, by Charmoy, in *Mémoires de l'acad. impér. de St Pétersbourg* (1836), pp. 270–321 and 441–471. (H. E.)

MIRROR (through O. Fr. *mirour*, mod. *miroir*, from a supposed Late Lat. *miratorium*, from *mirari*, to admire), an optical instrument which produces images of objects by reflection. In its usual forms it is simply a highly polished sheet of metal or of glass (which may or may not be covered, either behind or before, with a metallic film); a metallic mirror is usually termed a speculum. The laws relating to the optical properties of mirrors are treated in the article REFLECTION OF LIGHT.

Ancient Mirrors.—The mirror (*κάτοπτρον, ἔσοπτρον, ἔνοπτρον, speculum*) of the Etruscans, Greeks and Romans consisted of a thin disk of metal (usually bronze) slightly convex and polished on one side, the other being left plain or having a design incised upon it. A manufactory of mirrors of glass at Sidon is mentioned by Pliny (*Nat. Hist.* xxxvi. 66, 193), but they appear to have been little used (one has been found at San Remo). Glass mirrors were coated, but with tin; some silver mirrors have also been found. They are said to have been in use as early as the time of Pompey, and were common under the empire. Homer knows nothing of mirrors, but they are frequently mentioned in the tragedians and onwards. The usual size was that of an ordinary hand-mirror, but in imperial times some appear to have been large enough to take in the whole figure (Seneca, *Nat. quaest.*, i. 17, 8), being either fixed to the wall or working up and down like a window sash. The first specimen of a Greek mirror was not discovered till 1867, at Corinth, and the number extant is comparatively small. They are usually provided with a handle, which sometimes took the form of a statuette (especially of Aphrodite) supported on a pedestal, or consist of two metallic circular disks (the "box" mirrors) fitting in to each other, and sometimes fastened together by a hinge. The upper disk or cover was ornamented on the outside with a design in low relief; inside it was polished to reflect the face. The lower disk was decorated inside with engraved figures. The best specimens of both kinds of mirrors date from a little before 400 B.C. and last for some time after that. Of the reliefs, one of the best examples is "Ganymede carried away by the eagle"; amongst the incised mirrors may be mentioned one representing Leucas and Corinthus, inscribed with their names (both the above in Collignon, *L'Archéologie grecque*, 1907, figs. 212, 213); the Genius of the Cock-fights (*Revue archéologique*, new ser. xvii., 1868, Pl. 13). A bronze mirror-case, found at Corinth, has attached on the outside a relief representing an Eros with two girls; on the inside is incised a design of a nymph seated on a bench and playing with Pan at a game resembling the Italian *mora* (*Classical Review*, Feb. 1889, p. 86). On the back of another mirror in the British Museum (*Gazette archéologique*, ii. Pl. 27) is a figure of Eros which has been silvered over. With this was found the bronze case used to contain it, on the back of which is a group of Aphrodite and Eros in repoussé. It was found in Crete; but most of the Greek mirrors and mirror-cases having designs are from Corinth.

The principal feature of the Etruscan mirrors, the extant examples of which far outnumber the Greek, is the design incised on the back. Belonging chiefly to the 4th and 3rd centuries, they mostly resemble the Greek disk-mirrors in form, box-mirrors being rare. As a rule the subjects incised are taken from Greek mythology and legend (Trojan War, birth of Athena, Aphrodite and Adonis), the names of the persons represented being frequently added in Etruscan letters and orthography (Apul = Apollo, Achle = Achilles, Achmemrum = Agamemnon). Scenes from daily life, the toilet, the bath, the palaestra, also occur. In most cases the style of drawing, the types of the figures, and the manner of composing the groups are true to the characteristics of Greek art. Some may have been imported from Greece, but the greater number appears to have been more or less faithfully imitated from such designs as occurred on the Greek vases which the Etruscans obtained from Greece. Even where distinctly Etruscan figures are introduced, such as the heroes Aelius and Caelius Vibenna on a mirror in the British Museum, Greek models are followed. Although the work is frequently rough and careless, certain very fine and beautiful specimens have been found: the famous Semele-mirror, and the healing of Telephus, in which Achilles is shown scraping the healing rust from the lance with a crescent-shaped knife (Baumeister, *Denkmäler*, figs. 557, 1774). Roman mirrors are usually disk-mirrors, the back of the disk, if engraved, being generally ornamented with decorative patterns, not with any subject design.

Plain mirrors are found wherever Greek and Roman civilization spread, and a specimen found in Cornwall (now in the British Museum) shows that the Celtic population of England had adopted the form and substance of the mirror from their conquerors. This specimen is enriched with a Celtic pattern incised. The shape of the handle exhibits native originality. Mirrors were sometimes used in Greece for purposes of divination (Pausanias vii. 21, 5). The mirror was let down into a well by means of a string until it grazed the surface of the water with the rim; after a little while it was pulled up, and when looked into showed the face of the sick person, alive or dead, on whose behalf the ceremony had been performed. This took place at Patrae.

See J. J. de Witte, "Les miroirs chez les anciens," in *Extrait des annales de l'académie*, xxviii. (Antwerp, 1872); Mylonas, Ἑλληνικὰ κάτοπτρα (Athens, 1876); M. Collignon, *L'Archéologie grecque* (new ed., 1907; Eng. tr. by J. H. Wright, 1886); E. Gerhard, *Etruskische Spiegel* (1840–1867), continued by K. Klugmann and G. Körte (1884–1897); article in Smith's *Dictionary of Greek and Roman Antiquities* (3rd ed., 1891). (J. H. F.)

Medieval and Modern Mirrors.—Small metallic mirrors with a highly polished surface were largely used during the middle ages: pocket mirrors or small hand mirrors carried at the girdle being indispensable adjuncts to ladies' toilets. The pocket mirrors consisted of small circular plaques of polished metal, usually steel or silver, fixed in a shallow circular box covered with a lid. Mirror-cases were chiefly made of ivory, carved with relief representations of love or domestic scenes, hunting and games, and sometimes illustrations of popular poetry or romance. Gold and silver, enamels, ebony and other costly materials were likewise used for mirror cases, on which were lavished the highest decorative efforts of art workmanship and costly jewelling. The mirrors worn at the girdle had no cover, but were furnished with a short handle. In 625 Pope Boniface IV. sent Queen Ethelberga of Northumbria a present of a silver mirror; and in early Anglo-Saxon times mirrors were well known in England. It is a remarkable fact that on many of the sculptured stones of Scotland, belonging probably to the 7th, 8th or 9th century, representations of mirrors, mirror-cases and combs occur.

The method of backing glass with thin sheets of metal for mirrors was well known in the middle ages, at a time when steel and silver mirrors were almost exclusively employed. Vincent of Beauvais, writing about 1250, says that the mirror of glass and lead is the best of all, "quia vitrum propter transparentiam melius recipit radios"; and a *verre à mirer* is mentioned in the inventories of the dukes of Burgundy, dating from the 15th century. A gild of glass-mirror makers existed at Nuremberg in 1373, and small convex mirrors were commonly made in southern Germany before the beginning of the 16th century; and these continued to be in demand, under the name of bull's-eyes (*Ochsen-Augen*), till comparatively modern times. They were made by blowing small globes of glass into which while still hot was passed through the pipe a mixture of tin, antimony and resin or tar. When the globe was entirely coated with the metallic compound and cooled it was cut into convex lenses, which formed small but well-defined images. As early as 1317 a "Magister de Alemania," who knew how to work glass for mirrors, broke an agreement he had made to instruct three Venetians, leaving in their hands a large quantity of mixed alum and soot for which they could find no use. It was, however, in Venice that the making of glass mirrors on a commercial scale was first developed; and the republic enjoyed a much-prized monopoly of the manufacture for about a century and a half. In 1507 two inhabitants of Murano, representing that they possessed the secret of making perfect mirrors of glass, a knowledge hitherto confined to one German glass-house, obtained an exclusive privilege of manufacturing mirrors for a period of twenty years. In 1564 the mirror-makers of Venice, who enjoyed peculiar privileges, formed themselves into a corporation. The products of the Murano glass-houses quickly supplanted the mirrors of polished metal, and a large and lucrative trade in Venetian glass mirrors sprang up. They were made from blown cylinders of glass, which were slit, flattened on a stone, carefully polished, the edges frequently bevelled, and the backs "silvered" by an amalgam. The glass was remarkably pure and uniform, the "silvering" bright, and the sheets sometimes of considerable dimensions. In the inventory of his effects, made on the death of the French minister Colbert, a Venetian mirror, 46 by 26 in., in a silver frame, is valued at 8016 livres, while a picture by Raphael is put down at 3000 livres.

The manufacture of glass mirrors, with the aid of Italian workmen, was practised in England by Sir Robert Mansel early in the 17th century, and about 1670 the duke of Buckingham was concerned in glass-works at Lambeth where flint glass was made for looking-glasses. These old English mirrors, with bevelled edges in the Venetian fashion, are still well known. The Venetians guarded with the utmost jealousy the secrets of their manufactures, and gave exceptional privileges to those engaged in such industries. By their statutes any glass-maker carrying his art into a foreign state was ordered to return on the pain of imprisonment of his nearest relatives, and should he disobey the command emissaries were delegated to slay him. In face of such a statute Colbert attempted in 1664 to get Venetian artists transported to France to develop the two great industries of mirror-making and point-lace working. The ambassador, the bishop of Béziers, pointed out that this was to court the risk of being thrown into the Adriatic, and, further, that Venice was selling to France mirrors to the value of 100,000 crowns and lace to three or four times that value. Nevertheless, twenty Venetian glass-mirror makers were sent to France in 1665, and the manufacture was begun in the Faubourg St Antoine, Paris. But previous to this the art of blowing glass for mirrors had been practised at Tour-la-Ville, near Cherbourg, by Richard Lucas, Sieur de Nehou, in 1653; and by the subsequent combination of skill of both establishments French mirrors soon excelled in quality those of Venice. The art received a new impulse in France on the introduction of the making of plate glass in 1691. The St Gobain Glass Company attribute the discovery to Louis Lucas of Nehou, and over the door of the chapel of St Gobain they have placed an inscription in memory of "Louis Lucas qui inventa en 1691 le méthode de couler les glaces et installa la manufacture en 1695 dans le château de Saint Gobain."

Manufacture.—The term "silvering," as applied to the formation of a metallic coating on glass for giving it the properties of a mirror, was till quite recently a misnomer, seeing that till about 1840 no silver, but a tin amalgam, was used in the process. Now, however, a large proportion of mirrors are made by depositing on the glass a coating of pure silver, and the old amalgamation process is comparatively little used.

The process of amalgamation consists in applying a thin amalgam of tin and mercury to the surface of glass. A sheet of thin tin-foil, somewhat larger than the glass to be operated on, is spread out on a flat table, and after all folds and creases have been completely removed a small quantity of mercury is rubbed lightly and quickly over the whole surface, and the scum of dust, impure tin and mercury is taken off. Mercury is then poured upon the "quickened" foil until there is a body of it sufficient to float the glass to be silvered (about $\frac{1}{4}$ in. deep), and the glass (scrupulously cleaned simultaneously with the above operations) is slid over the surface of the mercury. Weights are placed over the surface until the greater part of the amalgamated mercury is pressed out, and the table is then tilted so that all superfluous mercury finds its way to the gutter. The glass is left twenty-four hours under weights; it is then turned over, silvered side up and removed to a drainer, where it dries and hardens. This process, when elaborated, yields excellent results, producing a brilliant silver-white metallic lustre, which is only subject to alteration by exposure to high temperatures or by contact with damp surfaces; but the mercurial vapours to which the workmen are exposed give rise to the most distressing and fatal affections.

The "silver on glass" mirror may be regarded as a discovery of J. von Liebig, who in 1835 observed that by heating aldehyde with an ammoniacal solution of silver nitrate in a glass vessel a brilliant deposit of metallic silver was formed on the surface of the glass. In practice the process was introduced about 1840; and it is now carried on, with several modifications, in two distinct ways, called the hot and the cold process respectively. In the former method there is employed a horizontal double-bottomed metallic table, which is heated with steam to from 35° to 40° C., and the reduction of the ammoniacal silver solution is effected with tartaric acid.

In silvering by the cold process advantage is taken of the power of sugar to reduce the silver nitrate. This method has been generally adopted for the silvering of mirrors for astronomical telescopes. G. W. Ritchey ("The Modern Reflecting Telescope," *Smithsonian Contributions to Knowledge*, xxxiv. 40) used the process devised by Brashear in 1884. The glass disk is mounted on a rocking-table, and most carefully cleaned with nitric acid, potash, and finally with distilled water. The reducing solution (which improves on keeping) is made up from 200 parts of water, 20 of loaf sugar, 20 of alcohol and 1 of nitric acid (commercial pure). The silver solution is prepared as follows: 2 parts of silver nitrate are dissolved in 20 parts of water, and strong ammonia added until the brown solution becomes clear. A solution of $1\frac{1}{2}$ parts of potash (pure by alcohol) in 20 of water is now added, and then ammonia until the solution is again clear. A solution of $\frac{1}{4}$ part of silver nitrate in 16 of water is added until the liquid is straw-coloured; it is then filtered. Quantities of the solutions, such that the sugar equals one half the nitrate, are taken, then diluted, mixed, and poured on to the plate, which is gently rocked. The liquid goes muddy-brown, and in 3 to 4 minutes it begins to clear, a thick deposit being formed in about 5 minutes. The solution is poured off, and water run on, the streaks of precipitate being removed by lightly held cotton wool. The washing is repeated, and then water is allowed to remain on the film for one hour. The water is then run off, and the plate is washed several times with alcohol, and then dried by an air fan. The film is now burnished with a chamois leather pad, and finally with the finest jewellers' rouge, the silver surface being the reflecting surface of the mirror.

The deposit of silver on glass is not so adherent and unalterable under the influence of sunlight and sulphurous fumes as the tin-mercury amalgam, and, moreover, real silvered glass has in many cases a slightly yellowish tinge. These defects have been overcome by a process introduced by Lenoir, which consists of brushing over the silvered surface with a dilute solution of cyanide of mercury, which, instantaneously forming a kind of amalgam, renders the deposit at once much whiter and more firmly adherent than before. To protect the thin metallic film from mechanical injury and the chemical action of gases and vapours it is coated with shellac or copal varnish, over which, when dry, are applied two coatings of red-lead paint or an electrolytically-deposited film of copper. This precaution only applies when the silver forms the back of the mirror.

Platinum Mirrors.—A cheap process of preparing mirror glass was to some extent prosecuted in France, whereby a thin but very adherent deposit of platinum is formed on the glass. A solution of chloride of platinum with a proportion of litharge and borate of lead dissolved in essential oil of spike is applied with a brush to well-cleaned glass, which is then placed on edge in a muffle furnace, and the platinum is thus burned in, forming an exceedingly thin but brilliant metallic backing having a somewhat grey lustre. It was used only for the lids of cheap boxes, toys, ornamental letters, &c.

Magic Mirrors.—Hand mirrors of metal are still in common use in Oriental countries, and in Japan bronze mirrors possess a religious significance. They have been known and used from the most remote period, mention of them being found in Chinese literature of the 9th century. The (reputed) first made Japanese mirror, preserved at Isé, is an object of the highest veneration in Japan, and an ancient mirror, connected with which is a tradition to the effect that it was given by the sun-goddess at the foundation of the empire, is a principal article of the Japanese regalia. The mirrors of Japan in general consist of thin disks, from 3 to 12 in. in diameter, of speculum metal with handles, cast in one piece. The polished face of the mirror is slightly convex in form, so that a reflected image is seen proportionately reduced in size; the back of the disk is occupied with ornamentation and inscriptions in bold relief, and its rim is also raised to the back. Much attention has been attracted to these mirrors by a singular physical peculiarity which in a few cases they are found to possess. These are known as magic mirrors from the fact that when a strong beam of light is reflected from their smooth and polished surface, and thrown on a white screen, an image of the raised ornaments and characters on the back of the mirror is formed with more or less distinctness in the disk of light on the screen. This peculiarity has at no time been specially observed by the Japanese, but in China it attracted attention as early as the 11th century, and mirrors possessed of this property sell among the Chinese at ten or even twenty times the price sought for the ordinary non-sensitive examples. The true explanation of the magic mirror was first suggested by the French physicist Charles Cléophas Person in 1847, who observed that the reflecting surface of the mirrors was not uniformly convex, the portions opposite relief surfaces being plane. Therefore, as he says, "the rays reflected from the convex portion diverge and give but a feebly illuminated image, while, on the contrary, the rays reflected from the plane portions of the mirror preserve their parallelism, and appear on the screen as an image by reason of their contrast with the feebler illumination of the rest of the disk." Such differences of plane in the mirror surface are accidental, being due to the manner in which it is prepared, a process explained by W. E. Ayrton and J. Perry (*Proc. Roy. Soc.*, 1878, vol. xxviii.), by whom ample details of the history, process of manufacture and composition of Oriental mirrors have been published. A preliminary operation in polishing the surface consists of scoring the cast disk in every direction with a sharp tool. The thicker portions with relief ornament offer more resistance to the pressure of the tool than the thin flat portions, which tend to yield and form at first a concave surface, but this by the reaction of its elasticity rises afterwards and forms a slightly convex surface, while the more rigid thick portions are comparatively little affected. This irregularity of surface is inconspicuous in ordinary light, and does not visibly distort images; but when the mirror reflects a bright light on a screen the unequal radiation renders the minute differences of surface obvious.

MIRZAPUR, a city and district of British India, in the Benares division of the United Provinces. The city is on the right bank of the Ganges; a station on the East Indian railway, about halfway between Allahabad and Benares, 509 m. N.W. from Calcutta. Pop. (1901), 79,862. The river front, lined with stone ghats or flights of stairs, mosques, Hindu temples and dwelling-houses of the wealthier merchants, is handsome; but the interior of the town is mainly composed of mud huts. Formerly it was the emporium of trade between central India and Bengal, which has now been diverted to the railways. It has European and native lace factories, and manufactures brass vessels and woollen carpets. The London Mission manages a high school and an orphanage. The municipal limits include the town of Bindhachal, an important centre of pilgrimage, with the shrine of Vindhyeshwari.

The DISTRICT OF MIRZAPUR extends into the Sone valley. Area, 5238 sq. m. It is crossed from east to west by the Vindhya and Kaimur ranges. A central jungly plateau connects these and separates the valley of the Ganges from that of the Sone. The part north of the Vindhyas is highly cultivated and thickly peopled, but the rest of the district consists largely of ravines and forests with a sparse population. The population in 1901 was 1,082,430, showing a decrease of 6·8% in the decade. The district comprises a large part of the hereditary domains of the raja of Benares, which are revenue-free. It is traversed, near the Ganges, by the main line of the East Indian railway. The Great Southern road used to start from the city.

MISCARRIAGE, in its widest sense a going astray, a failure. In law, the word is used in several phrases; thus, a miscarriage of justice is a failure of the law to attain its ends. In the Statute of Frauds (29 Car. II., c. 3) in the expression "debt, default or miscarriage of another," the word has sometimes been interpreted as equivalent in meaning to default, but it is more usually considered to mean a species of wrongful act for the consequence of which the law makes a party civilly responsible. The term is also used (see ABORTION) for the premature expulsion of the contents of the womb before the period of gestation is complete.

MISCEGENATION (from Lat. *miscere*, to mix, and *genus*, race), a mixture or blending of two races, particularly of a white with a black or negro race.

MISCELLANY, a term applied to a single book containing articles, treatises or other writings dealing with a variety of different subjects. It is a common title in the literature of the 17th and 18th centuries. The word is an adaptation of Lat. *miscellanea* (from *miscellaneus*, mixed, *miscere*, to mix), used in this sense by Tertullian, *Miscellanea Ptolemaei* (Tert. *adv. Val.* 12); the ordinary use of the word in Latin was for a dish of broken meats, applied by Juvenal (xi. 20) to the coarse food of gladiators.

The Lat. *miscellaneus* has affected the form of a word which is now usually spelled "maslin," applied to a mixture of various kinds of grain, especially rye and wheat. This, however, is really from the O. Fr. *mesteillon*; Late Lat. *mistilio*, formed from *mistus*, past participle of *miscere*, to mix, mingle.

MISCHIEF, a term meaning originally calamity, trouble; now used particularly of annoying injuries or damage done in play or through petty spite. The word is derived through O. Fr. *meschef*, mod. *méchef*, from *meschever*, to do wrong, *mes-*, amiss, and *chever*, bring to a head (*chef*, Lat. *caput*).

MISDEMEANOUR (from O. Fr. *mes-* and *demener*, to conduct oneself ill), the generic term used in English law to include all those offences against the criminal law which are not by common law or statute made treason or felony. In *Russell on Crimes* it is defined as a crime for which the law has not provided a particular name (6th ed., i. 193). The term misprision, at one time applied to the more heinous offences of this class, is now almost obsolete. The term misdemeanour includes not only all indictable offences below the degree of felony, some of them grave crimes, such as sedition, riot and perjury, but also the petty misdemeanours, which may be dealt with summarily by justices of the peace, and the most trifling breaches of local by-laws.

As a matter of legal history, many misdemeanours now represent what were originally described as trespasses against the peace, a phrase which is equivalent to a "tort" or delict, accompanied by circumstances calling for prosecution in the interest of the Crown and the public as well as for civil proceedings by the injured parties. Such acts as riot, public nuisance, sedition and the different forms of libel naturally came to be regarded as wrongs against the king's peace. Many of the early statutes anent justices are particularly concerned with the punishment of rioters; and some offences now treated as misdemeanours belonged to the spiritual and not to the temporal courts, *e.g.* perjury.

While it is true that almost all crimes which in the middle ages were considered heinous fall into the categories of treason or felony, many statutory misdemeanours differ so little, if at all, from felony in character or in the mode of punishment that, in the absence of a code, no logical line of division can now be drawn, inasmuch as few felonies are now capital and none involve the forfeitures of land or goods, which at one time afforded an appreciable distinction between the two categories of crime. The result is that it is impossible to distinguish without enumerating the specific crimes falling under each head.

Among the chief *misdemeanours* are: (1) Assault on the sovereign; (2) unlawful assembly; (3) riot and sedition; (4) forcible entries; (5) perjury, which until 1563 was mainly, if not solely, cognizable by the spiritual courts; (6) blasphemy; (7) extortion; (8) bribery; (9) obtaining property by false pretences (which is nearly cognate to the felony of larceny); (10) assault; (11) public nuisance; (12) libel; (13) conspiracy to defraud, &c.; (14) attempts to commit other crimes.

Numerous acts or omissions are punishable as "misdemeanours by interpretation." In other words, disobedience to the command or prohibition of a statute as to a matter of public concern is indictable as a misdemeanour, even if the statute does not so describe it, unless the terms of the statute indicate that some other remedy alone is to be pursued. For some misdemeanours penal servitude may be imposed by statute. But as a rule the appropriate punishment is by fine or imprisonment without hard labour or both, at the discretion of the court unless limited by a particular statute. The offender may also be put under recognizance to keep the peace and be of good behaviour. Theoretically, whipping may be imposed; but this is not now done except under specific statutory authority: and the like authority is necessary to authorize the addition of hard labour to a sentence of imprisonment.

At the present time the practical difference in English law between misdemeanour and felony lies in matters of procedure, in which a trial for misdemeanour closely resembles an ordinary civil trial.

1. An arrest for misdemeanour may not be made without judicial authority except under specific statutory authority.
2. A person charged with misdemeanour is entitled to bail (see ARREST), *i.e.* to release on the obtaining of sureties, or even on his own recognizance without sureties to appear and take his trial. Bail is obligatory in all misdemeanours, with the exception of misdemeanours where the costs of the prosecution are payable out of the county or borough rate or fund.
3. A misdemeanour may be tried on an information filed by the attorney-general or by leave of the high court without the indictment essential in cases of treason and felony.
4. The same indictment or information may include a number of charges of misdemeanour committed at different times and even against different persons. See INDICTMENT.
5. A trial for misdemeanour may proceed in the absence of the defendant, who is not "given in charge" to the jury, as in the case of felony.
6. On a charge of misdemeanour a trial by special jury may be ordered.
7. There is no right to challenge peremptorily any of the jurors summoned to try the case; any challenge made must be for cause. The jury is sworn collectively (four men to a book), and not poll by poll as in felony, and their oath is to try the issues joined between the king and the defendant. They may separate during adjournments of the trial, like a jury in a civil case.
8. The costs of prosecuting certain misdemeanours are recoverable out of public funds under specific statutory provisions; but in very few cases can the court make the misdemeanant himself pay them.
9. There are no accessories after the fact to misdemeanour. (See ACCESSORY.)

Under French law and systems based thereon or having a common origin a distinction is drawn between *crime* (*verbrechen*), *délit* (*vergehen*) and *contravention*. The English term misdemeanour roughly corresponds to the two classes of *délit* and *contravention* but includes some offences which would be qualified as "crime." In the criminal code of Queensland the term "misdemeanour" is retained, while that of "felony" is abolished; and offences are classified as crimes, misdemeanours and simple offences, the two former punishable on indictment, the latter on summary conviction only; the more serious offences described in English law as misdemeanours are in that code described as crimes (*e.g.* perjury). In the United States the English common law as to misdemeanour is generally followed, but in New York and other states a statutory distinction has been made between misdemeanour and felony by defining the latter as a crime punishable by death or by imprisonment in a state prison. (W. F. C.)

MISE, an Anglo-French term (from Fr. *mettre*, to place) signifying a settlement of accounts, disputes, &c., by agreement or arbitration. As an English legal term it was applied to the issue in a writ of right; and in history to the payment, in return for certain privileges, made by the county palatine of Chester to each new earl, and by the Welsh to each new lord of the Marches, or to a prince or king on his entry into the country. In its more general sense of agreement the term is familiar in English history in the "Mise of Amiens," in January, and that of Lewes, in May of 1264, made between Henry III. and the barons.

MISENUM, an ancient harbour town of Campania, Italy, about 3 m. S. of Baiae (*q.v.*) at the western extremity of the Gulf of Puteoli (Pozzuoli). Until the end of the Republic it was dependent on Cumae, and was a favourite villa resort. Agrippa made the fine natural harbour into the main naval station of the Mediterranean fleet, and founded a colony there probably in 31 B.C. The emperor Tiberius died in his villa here. Its importance lasted until the decline of the fleet in the 4th century A.D. It was at first an independent episcopal see: Gregory the Great united it with that of Cumae. In 890 it was destroyed by the Saracens. The name was derived from one of the companions of Ulysses, or from Aeneas' trumpeter, an account of whose burial is given in Virgil, *Aeneid*, vi. 232.

The harbour consisted of the outer basin, or Porto di Miseno, protected by moles, of which remains still exist, and the present Mare Morto, separated from it by a comparatively modern embankment. The town lay on the south side of the outer harbour, near the village of Miseno, where remains of a theatre and baths and the inscriptions relating to the town have been found. Remains of villas can also be traced, and to the largest of these, which occupied the summit of the promontory, and belonged first to Marius, then to Lucullus, and then to the imperial house, probably belongs the subterranean Grotta Dragonara. Roads ran north to Baiae and north-west past the modern Torre Gaveta to Cumae: along the line of both are numerous columbaria.

See J. Beloch, *Campanien*, ed. ii. (Breslau, 1890), 190 sqq. (T. As.)

MISER, a term originally meaning (as in Latin) miserable or wretched, but now used for an avaricious person who hoards up money and who spends the smallest possible sum on necessities.

MISERERE (the imperative of Lat. *misereri*, to have mercy or pity), the name of one of the penitential psalms (*li.*), from its opening words, *Miserere mei, Deus*. The word is frequently used in English as equivalent to "Misericord" (Lat. *misericordia*, pity, compassion) for various forms in which the rules of a monastic order or general discipline of the clergy might be relaxed; thus it is applied to a special chamber in a monastery for those members who were allowed special food, drink, &c., and to a small bracket on the under side of the seat in a stall of a church made to turn up and afford support to a person in a position between sitting and standing. "Misericord" and "miserere" are also used of a small dagger, the "dagger of mercy," capable of passing between the joints of armour, with which the *coup de grâce* might be given to a wounded man.

MISHAWAKA, a city of St Joseph county, Indiana, U.S.A., on the St Joseph river of Michigan, about 80 m. E. by S. of Chicago. Pop. (1900), 5560 (821 foreign-born); (1910) 11,886. It is served by the Grand Trunk and the Lake Shore & Michigan Southern railways, and by inter-urban electric lines. It has an extensive trade in grain and other agricultural products. Two miles up the river is the Hen Island dam, which, with the Mishawaka hydraulic dam nearer the city, is the source of much of the power used by the city's manufactories. St Joseph Iron Works was laid out on the south side of the river, in 1833, and in 1835 was organized as a village and two additions were platted. In 1836 Indiana City was laid out on the north side of the river;

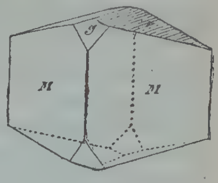
and in 1839 St Joseph Iron Works, with its two additions, and Indiana City were incorporated as one town named Mishawaka—the name of an Indian village formerly occupying a part of the present site. Mishawaka was chartered as a city in 1899.

MISHMI, a hill-tribe on the frontier of Eastern Bengal and Assam. The Mishmis occupy the hills from the Dihong to the Brahmakund, in the north-eastern corner of the Brahmaputra valley. In 1854 M. Krick and M. Bourry, two French missionaries, were murdered in the Mishmi country, but their death was avenged by a small expedition which took the murderer prisoner. In 1899 another British expedition was sent against the Mishmis, owing to the murder of some British subjects.

MISIONES, a territory of northern Argentina, bounded N. by Paraguay and Brazil, E. and S. by Brazil and W. by Paraguay and the Argentine province of Corrientes. Its boundary lines are formed by the upper Paraná and Iguassú rivers on the N., the San Antonio and Pequiry-guassu streams on the E. and the Uruguay River on the S. Area, 11,282 sq. m.; pop. (1904, estimate), 38,755, chiefly Indians and *mestizos*. The territory is a region of roughly-broken surfaces, divided longitudinally by low mountains, called the Sierra Iman and Sierra Grande de Misiones, which form the water-parting for many small streams flowing northward to the Paraná and southward to the Uruguay. The greater part of the country is covered with forest and tropical jungle. The climate is sub-tropical, the temperature ranging from 40° to 95° F. The soil is described as highly fertile, but its products are chiefly confined to *yerba mate* or Paraguay tea (*Ilex paraguayensis*), tobacco and oranges and other fruits. Communication with the capital is maintained by two lines of steamboats running to Corrientes and Buenos Aires, but a railway across Paraguay from Asunción is planned to Encarnación, opposite Posadas. Some of the Jesuit missions of the 17th and 18th centuries were established in this territory, and are to-day represented by the lifeless villages of Candelaria, Santa Ana, San Ignacio and Corpus along the Paraná River, and Apóstoles, Concepción, and San Javier along the Uruguay. Posadas (estimated pop. in 1905, 8000), the capital, on the Paraná, officially dates from 1865. It was also a Jesuit settlement called Itapua, though the large mission of that name was on the Paraguayan side of the river. It is at the extreme west of the territory, and is the terminal port for the steamers from Corrientes.

MISKOLCZ, capital of the county of Borsod, Hungary, 113 m. N.E. of Budapest by rail. Pop. (1900), 40,833. It is situated in a valley watered by the Szinva in the east of the Bükk mountains, and opens towards the south to the plain of the Sajó, an affluent of the Hernád. Miskolcz is a thriving town, and among its buildings are a Roman Catholic church of the 13th century in Late Gothic style, a Minorite convent, and Greek Catholic, Lutheran and Calvinist churches. It manufactures snuff, porcelain, boots and shoes, and prepared leather, and has both steam and water mills. It trades in grain, flour, wine, fruit, cattle, hides, honey, wax and agricultural products, while four well-attended fairs are held annually. About 5 m. west of the town in the Szinva valley is Diósgyör (pop. 11,520), which possesses important iron-works, and the ruined castle of Diósgyör, formerly a shooting residence of the kings of Hungary. About 4 m. to the south-west of Miskolcz are the baths of Tapolcza, containing warm springs. To the south-west of the town lies Onod (pop. 2087), to the south of which, on the banks of the Sajó, is the heath of Mohi or Muhi, famous as the scene of the great defeat of the Hungarians by the Mongols in 1241. About 85,000 Hungarians fell, and the whole country was devastated for the next two years by the Mongolian hordes. During the 16th and 17th centuries Miskolcz suffered much from the Ottomans, and from the troops of George Rákóczy and Emeric Tökölyi. In 1781, 1843 and 1847 it was devastated by fire, and on the 30th of August 1878 a great portion of the town was ruined by a terrific storm.

MISPICKEL, a mineral consisting of iron sulpharsenide, $FeAsS$; it contains 46% of arsenic, and is of importance as an ore of this element. It is known also as arsenopyrite or arsenical pyrites (Ger. *Arsenikkies*): mispickel is an old name of German origin, and in the form *Mistpuckel* was used by G. Agricola in 1546. The crystals are orthorhombic, with angles similar to those of marcasite; they are often prismatic in habit, and the prism *M* is usually terminated by the deeply striated faces of an obtuse dome *r*. Twinning is not uncommon, the twin-planes *M* (110) and *g* (101) being the same as in marcasite. The colour of the mineral is silver-white or steel-grey, with a metallic lustre, but it is often tarnished yellow; the streak is greyish-black. The hardness is 5$\frac{1}{2}$–6, and the specific gravity 5·9–6·2.



Mispickel occurs in metalliferous veins with ores of tin, copper, silver, &c. It is occasionally found as embedded crystals, for example, in serpentine at Reichenstein, Silesia. In Cornwall and Devon it is associated with cassiterite in the tin-lodes, but is also found in the copper-lodes: well crystallized specimens have been obtained from the neighbourhood of Tavistock, Redruth and St Agnes. Mispickel is the principal source of arsenious oxide or the "white arsenic" of commerce (see ARSENIC). The chief supplies are from Cornwall and Devon, and Freiberg in Saxony, and from Canada and the United States.

Danaite is a cobaltiferous variety of mispickel, containing up to 9% of cobalt replacing iron; it was first noticed by J. F. Dana in 1824 at Franconia in New Hampshire. This variety forms a passage to the species glaucodote, $(Co,Fe)AsS$, which is found as well-developed orthorhombic crystals in copper ore at Håkansboda in Ramberg parish, Vestmanland, Sweden. Other species belonging to this isomorphous group of orthorhombic minerals are marcasite (FeS_2), löllingite ($FeAs_2$), safflorite ($CoAs_2$) and rammelsbergite ($NiAs_2$). (L. J. S.)

MISPRISION (from O. Fr. *mesprendre*, mod. *méprendre*, to misunderstand), a term in English law, almost obsolete, used to describe certain kinds of offence. Writers on criminal law usually divide misprision into two kinds (*a*) negative, (*b*) positive.

(*a*) Negative misprision is the concealment of treason or felony. By the common law of England it was the duty of every liege subject to inform the king's justices and other officers of the law of all treasons and felonies of which the informant had knowledge, and to bring the offender to justice by arrest (see Sheriffs Act 1887, s. 8). The duty fell and still falls primarily on the grand jurors of each county borough or franchise, and is performed by indictment or presentment, but it also falls in theory on all other inhabitants (see Pollock and Maitland, *Hist. Eng. Law*, ii. 505). Failure by the latter to discharge this public duty constitutes what is known as misprision of treason or felony (see 3 Co. Inst., 139).

Misprision of Treason, in the words of Blackstone, "consists in the bare knowledge and concealment of treason, without any degree of assent thereto, for any assent makes the party a principal traitor." According to Bracton, *de Coronâ*, seq. 118, failure to reveal the treason of another was in itself high treason, but statutes of 1551–1552 and 1554–1555 made concealment of treason misprision only. Most of the statutes regulating procedure on trials for treason also apply to misprision of treason. The punishment is loss of the profit of the lands of the offender during life, forfeiture of all his goods and imprisonment for life. These punishments are not affected by the Forfeiture Act 1870.

Misprision of Felony is the concealment of a felony committed by another person, but without such previous concert with, or subsequent assistance of the offender, as would make the concealer an accessory before or after the fact. The offence is a misdemeanour punishable on indictment by fine and imprisonment.

(*b*) Positive misprision is the doing of something which ought not to be done; or the commission of a serious offence falling short of treason or felony, in other words of a misdemeanour of a public character (*e.g.* maladministration of high officials, contempt of the sovereign or magistrates, &c.). To endeavour to dissuade a witness from giving evidence, to disclose an examination before the privy council, or to advise a prisoner to stand mute, used to be described as misprisions (Hawk. P. C. bk. I. c. 20).

The old writers say that a misprision is contained in every felony and that the Crown may elect to prosecute for the misprision instead of the felony. This proposition merely affirms the right of the Crown to choose a more merciful remedy in certain cases, and has no present value in the law. Positive misprisions are now only of antiquarian interest, being treated as misdemeanours.

In the United States, misprision of treason is defined to be the crime committed by a person owing allegiance to the United States, and having knowledge of the commission of any crime against them, who conceals and does not, as soon as may be, disclose and make known the same to the president or to some judge of the United States, or to the governor, or to some judge or justice of a particular state. The punishment is imprisonment for not more than seven years and a fine of not more than one thousand dollars.

MISRULE, LORD OF, in medieval times the master of the Christmas revels. Probably J. G. Frazer (*Golden Bough* III.) is right in suggesting that the lord or abbot of misrule is the successor of the king of the ancient Roman Saturnalia, who personated Saturn and suffered martyrdom at the end of the revels. Compare, too, the burlesque figure at the carnival, which is finally destroyed. Stow (*Survey*) writes: "In the feast of Christmas there was in the King's House, wheresoever he lodged, a Lord of Misrule or Master of merry disports, and the like had ye in the house of every nobleman of honour or good worship, were he spiritual or temporal." The mayor and sheriffs of London also had Lords of Misrule. These mock-monarchs began their reign on Allhallows Eve, and misruled till Candlemas. In Scotland they were known as "Abbots of Unreason," and in 1555 a special act suppressing them was passed. In Tudor times their reign was marked by much display and expense. In Henry VIII.'s reign an order for a fool's coat is signed by six of the Privy Council. By an Act of Common Council (1555) the city expenses of the Lords of Misrule were severely curtailed. Machyn speaks of a Lord of Misrule who in 1561 rode through London followed by a hundred gentlemen on horseback hung with gold chains (see also REVELS, MASTER OF).

MISSAL, the book containing the liturgy, or office of the mass (*missa*), of the Roman Catholic Church. This name (*e.g.* Missale gothicum, francorum, gallicanum vetus) began to supersede the older word *Sacramentary* (sacramentarium, liber sacramentorum) from about the middle of the 8th century.[1] At that period the book so designated contained merely the fixed canon of the mass or consecration prayer (actionem, precem canonicam, canonem actionis), and the variable collects, secretae or orationes super oblata, prefaces, and post-communions for each fast, vigil, festival or feria of the ecclesiastical year; for a due celebration of the Eucharist they required accordingly to be supplemented by other books, such as the *Antiphonarium*, afterwards called the *Graduale*, containing the proper antiphons (introits), responsories (graduals), tracts, sequences, offertories, communions and other portions of the communion service designed to be sung by the schola or choir, and the *Lectionarium* (or *epistolarium* and *evangelistarium*) with the proper lessons.[2] Afterwards missals contained more or less fully the antiphons and lessons as well as the prayers proper to the various days, and these were called *missalia plenaria*. All modern missals are of this last description. The *Missale romanum ex decreto ss. concilii tridentini restitutum*, now in almost exclusive use throughout the Latin obedience, owes its present form to the council of Trent, which undertook the preparation of a correct and uniform liturgy, and entrusted the work to a committee of its members. This committee had not completed its labours when the council rose, but the pope was instructed to receive its report when ready and to act upon it. The "reformed missal" was promulgated by Pius V. on the 14th of July 1570, and its universal use enjoined, the only exceptions being churches having local liturgies which had been in unbroken use for at least two centuries.[3] It has subsequently undergone slight revisions under Clement VIII. (1604), Urban VIII. (1634) and Leo XIII. (1884), and various new masses, both obligatory and permissive, universal and local, have been added. Although the Roman is very much larger than any other liturgy, the communion office is not in itself inordinately long. The greater part of it is contained in the "ordinary" and "canon" of the mass, usually placed about the middle of the missal, and occupies, though in large type, only a few pages. The work owes its bulk and complexity to two circumstances. On the one hand, in the celebration of the sacrifice of the mass practically nothing is left to the discretion of the officiating priest; everything—what he is to say, the tone and gestures with which he is to say it, the cut and colour of the robe he is to wear—is carefully prescribed in the rubrics.[4] On the other hand, the Roman, like all the Western liturgies, is distinguished from those of the Eastern Church by its flexibility. A distinctive character has been given to the office for each ecclesiastical season, for each fast or festival of the year, almost for each day of the week; and provision has also been made of a suitable communion service for many of the special occasions both of public and of private life.

The different parts of the Roman communion office are not all of the same antiquity. Its essential features are most easily caught, and best understood, by reference to the earliest *Sacramentaries* (particularly the Gregorian, which was avowedly the basis of the labours of the Tridentine committee), to the Gregorian *Antiphonary*, and to the oldest redaction of the *Ordo romanus*.[5] The account of the mass (qualiter Missa Romana celebratur) as given by the *sacramentarium gregorianum* is to the effect that there is in the first place "the *Introit* according to the time, whether for a festival or for a common day; thereafter *Kyrie eleison*. (In addition to this *Gloria in excelsis Deo* is said if a bishop be [the celebrant], though only on Sundays and festivals; but a priest is by no means to say it, except only at Eastertide. When there is a litany (quando letania agitur) neither *Gloria in excelsis* nor *Alleluia* is sung.) Afterwards the *Oratio* is said, whereupon follows the *Apostolus*, also the *Gradual* and *Alleluia*. Afterwards the *Gospel* is read. Then comes the *Offertorium*,[6] and the *Oratio super oblata* is said." Then follow the *Sursum corda*, the *Preface*, *Canon*, Lord's Prayer and "embolism" (ἐμβόλισμα or insertion, *Libera nos, Domine*), given at full length precisely as they still occur in the Roman missal.

---

[1] It first occurs in Ecgbert of York's *De remediis peccatorum*, where it refers to the sacramentary of Gregory the Great.

[2] One of the most celebrated of early missals is the Stowe missal of the 6th century in the British Museum. It contains the litany of the saints, the *gloria* with the collects, the part of the Epistle to the Corinthians relating to the Eucharist, the *credo* and the *consecratio* and *memento* corresponding exactly to the Roman canon. After the daily mass follow the *missa apostolorum*, *missa sanctorum*, *missa pro poenitentibus vivis* and the *missa pro mortuis*. To the 7th century belong the *Missale francorum* and the *Missale gothicum*, originally in the abbey of Fleury. In the 8th century we find in Ecgbert of York's *De remediis peccatorum*, i., that those who devote their lives to sacred orders are supposed to furnish themselves with a psalter, lectionary, antiphonary, missal, baptismal office and martyrology. The adoption of the Roman liturgy by Charlemagne explains the great quantity of missals within this period; *e.g.* the missal of Worms in the library of the Arsenal at Paris. From the 10th century we have the missal of St Vougay, although badly mutilated, and several others. From the 12th century missals became common, and more so with the invention of printing.

[3] The English missal consequently continued to be used by English Roman Catholics until towards the end of the 17th century, when it was superseded by the Roman through Jesuit influence. The Gallican liturgy held its ground until much more recently, but has succumbed under the Ultramontanism of the bishops.

[4] In all the older liturgies the comparative absence of rubrics is conspicuous and sometimes perplexing. It is very noticeable in the Roman *Sacramentaries*, but the want is to some extent supplied by the very detailed directions for a high pontifical mass in the various texts of the *Ordo Romanus* mentioned below. That there was no absolutely fixed set of rubrics in use in France during the 8th century is shown by the fact that each priest was required to write out an account of his own practice ("libellum ordinis") and present it for approbation to the bishop in Lent (see Baluze, *Cap. Reg. Franc.* i. 824, quoted in Smith's *Dict. of Chr. Antiq.* ii. 1521).

[5] For the genealogical relationships of the Roman with other liturgies, see LITURGY. For the doctrines involved in the "sacrifice of the mass," see EUCHARIST.

[6] Some editions do not mention the Offertory here.

In every liturgy of all the five groups a passage similar to this occurs, beginning with *Sursum corda*, followed by a *Preface* and the recitation of the *Sanctus* or Angelic Hymn. The "canon" or consecration prayer, which in all of them comes immediately after, invariably contains our Lord's words of institution, and (except in the Nestorian liturgy) concludes with the Lord's Prayer and "embolism." But there are certain differences of arrangement, by which the groups of liturgies can be classified. Thus it is distinctive of the liturgy of Jerusalem that the "great intercession" for the quick and the dead follows the words of institution and an Epiklesis (ἐπίκλησις τοῦ πνεύματος ἁγίου) or petition for the descent of the Holy Spirit upon the gifts; in the Alexandrian the "great intercession" has its place in the *Preface*; in the East Syrian it comes between the words of restitution and the Epiklesis; in the Ephesine it comes before the *Preface*; while in the Roman it is divided into two, the commemoration of the living being before, and that of the dead after, the words of institution. Other distinctive features of the Roman liturgy are (1) the position of the "Pax" after the consecration, and not as in all the other liturgies at a very early stage of the service, before the *Preface* even; and (2) the absence of the Epiklesis common to all the others.[1] The words of its "canonical prayer" are of unknown antiquity; they are found in the extant manuscripts of the *Sacramentarium gelasianum*, and were already old and of forgotten authorship in the time of Gregory the Great, who, in a letter to John, bishop of Syracuse (*Registr. Epist.* vii. 64), speaks of it as "the prayer composed by a 'scholastic'" (precem quam scholasticus composuerat). The same letter is interesting as containing Gregory's defence, on the ground of ancient use, of certain parts of the Roman ritual to which the bishop of Syracuse had taken exception as merely borrowed from Constantinople. Thus we learn that, while at Constantinople the *Kyrie eleison* was said by all simultaneously, it was the Roman custom for the clergy to repeat the words first and for the people to respond, *Christe eleison* being also repeated an equal number of times. Again, the Lord's Prayer was said immediately after the consecration aloud by all the people among the Greeks, but at Rome by the priest alone.

The meagre liturgical details furnished by the *Sacramentarium gregorianum* are supplemented by the texts of the *Ordo romanus*, the first of which dates from about the year 730. The ritual they enjoin is that for a pontifical high mass in Rome itself; but the differences to be observed by a priest "quando in statione facit missas" are comparatively slight. Subjoined is a précis of *Ordo Romanus I.*

It is first of all explained that Rome has seven ecclesiastical regions, each with its proper deacons, subdeacons and acolytes. Each region has its own day of the week for high ecclesiastical functions, which are celebrated by each in rotation. [This accounts for the Statio ad S. Mariam Majorem, ad S. Crucem in Jerusalem, ad S. Petrum, &c., prefixed to most of the masses in the *Gregorian Sacramentary*, and still retained in the "Proprium de Tempore" of the Roman missal.] The regulations for the assembling and marshalling of the procession by which the pontiff is met and then escorted to the appointed station are minutely given, as well as for the adjustment of his vestments "ut bene sedeant," when the sacristy has been reached. He does not leave the sacristy until the *Introit* has been begun by the choir in the church. Before the *Gloria* he takes his stand at the altar, and after the *Kyrie Eleison* has been sung (the number of times is left to his discretion) he begins the *Gloria in excelsis*, which is taken up by the choir. During the singing he faces eastward; at its close he turns round for a moment to say "Pax vobis," and forthwith proceeds to the *Oratio*.[2] This finished, all seat themselves in order while the subdeacon ascends the ambo and reads [the *epistle*]. After he has done, the cantor with his book (cantatorio) ascends and gives out the response (*Responsum*) with the *Alleluia* and *Tractus* in addition if the season calls for either. The deacon then silently kisses the feet of the pontiff and receives his blessing in the words "Dominus sit in corde tuo et in labiis tuis." Preceded by acolytes with lighted candles and subdeacons burning incense, he ascends the ambo, where he reads the *Gospel*. At the close, with the words "Pax tibi" and "Dominus vobiscum," the pontiff,[3] after another *Oratio*, descends to the "senatorium" accompanied by certain of the inferior clergy, and receives in order the oblations of the rulers (oblationes principum), the archdeacon who follows taking their "amulas" of wine and pouring them into a larger vessel; similar offerings are received from the other ranks and classes present, including the women. This concluded, the pontiff and archdeacon wash their hands, the offerings being meanwhile arranged by the subdeacons on the altar, and water, supplied by the leader of the choir (archiparaphonista), being mingled with the wine. During this ceremony the schola have been engaged in singing the *Offertorium*; when all is ready the pontiff signs to them to stop, and enters upon the *Preface*, the subdeacons giving the responses. At the Angelic Hymn (*Sanctus*) all kneel and continue kneeling, except the pontiff, who rises alone and begins the *Canon*. At the words "per quem haec omnia" the archdeacon lifts the cup with the oblates, and at "Pax Domini sit semper vobiscum," he gives the peace to the clergy in their order, and to the laity. The pontiff then breaks off a particle from the consecrated bread and lays it upon the altar; the rest he places on the paten held by the deacon. It is then distributed while *Agnus Dei* is sung. The pontiff in communicating puts the particle into the cup, saying, "Fiat commixtio et consecratio corporis et sanguinis Domini nostri Jesu Christi accipientibus nobis in vitam aeternam." Those present communicate in their order under this species also. As the pontiff descends into the senatorium to give the communion, the schola begins the communion *Antiphon*, and continues singing the *Psalm* until, all the people having communicated, they receive the sign to begin the *Gloria*, after which, the verse having been again repeated, they stop. The celebrant, then, facing eastward, offers the *Oratio ad complendum*, which being finished the archdeacon says to the people, "Ite, missa est," they responding with "Deo gratias."

To complete our idea of the Roman communion office as it was prior to the end of the 8th century we must now turn to the Gregorian *Antiphonarius sive gradualis liber ordinatus per circulum anni*, which as its name implies contains those variable portions of the mass which were intended to be sung by the schola or choir. It gives for each day for which a proper mass is provided: (1) the *Antiphona* (Antiphona ad Introitum) and *Psalmus*; (2) the *Responsorium* and *Versus*, with its *Alleluia* and *Versus*; (3) the *Offertorium* and *Versus*; (4) the *Communio* and *Psalmus*. Some explanation of each of these terms is necessary. (1) The word *Antiphon* (ἀντίφωνον, O.Eng. *Antefn*, Eng. *Anthem*) in its ecclesiastical use has reference to the very ancient practice of relieving the voices of the singers by dividing the work between alternate choirs. In one of its most usual meanings it has the special signification of a sentence (usually scriptural) constantly sung by one choir between the verses of a psalm or hymn sung by another. According to the Roman liturgiologists it was Pope Celestine who enjoined that the Psalms of David should be sung (in rotation, one presumes) antiphonally before mass; in process of time the antiphon came to be sung at the beginning and end only, and the psalm itself was reduced to a single verse. In the days of Gregory the Great the introit appears to have been sung precisely as at present—that is to say, after the antiphon proper, the *Psalmus* with its *Gloria*, then the antiphon again. (2) The *Responsorium*, introduced between the epistle and gospel, was probably at first an entire psalm or canticle, originally given out by the cantor from the steps from which the epistle had been read (hence the later name *Graduale*), the response being taken up by the whole choir. (3) The *Offertorium* and *Communio* correspond to the "hymn from the book of Psalms" mentioned by early authorities (see, for example, Augustine, *Retr.* ii. 11; *Ap. Const.* viii. 13) as sung before the oblation and also while that which had been offered was being distributed to the people. A very intimate connexion between these four parts of the choral service can generally be observed; thus, taking the first Sunday in the ecclesiastical year, we find both in the *Antiphonary* and in the modern *Missal* that the antiphon is Ps. xxv. 1-3, the psalmus Ps. xxv. 4, the responsorium (graduale) and versus Ps. xxv. 3 and xxv. 4, the offertorium and versus Ps. xxv. 1-3 and xxv. 5. The communio is Ps. lxxxv. 12, one of the verses of the responsorium being Ps. lxxxv. 7. In the selection of the introits there are also traces of a certain rotation of the psalms in the Psalter having been observed.

The first pages of the modern Roman missal are occupied with the *Calendar* and a variety of explanations relating to the year and its parts, and the manner of determining the movable feasts. The general rubrics (*Rubricae generales missalis*) follow, explaining what are the various kinds of mass which may be celebrated, prescribing the hours of celebration, the kind and colour of vestments to be used, and the ritual to be followed (ritus celebrandi missam), and giving directions as to what is to be done in case of various defects or imperfections which may arise. The *Praeparatio ad missam*, which comes next, is a short manual of devotion containing psalms, hymns and prayers to be used as opportunity may occur before and after celebration. Next comes the proper of the season (*Proprium missarum de tempore*), occupying more than half of the entire volume. It contains the proper introit, collect (one or more), epistle, gradual (tract or sequence), gospel, offertory, secretae (one or more), communion and post-communion for every Sunday of the year, and also for the festivals and ferias connected with the ecclesiastical seasons, as well as the offices peculiar to the ember days, Holy Week, Easter and Whitsuntide. Between the office for Holy Saturday and that for Easter Sunday the ordinary of the mass (*Ordo missae*), with the solemn and proper prefaces for the year, and the canon of the mass are inserted. The proper of the season is followed by the proper of the saints (*Proprium sanctorum*), containing what is special to each saint's day in the order of the calendar, and by the *Commune sanctorum*, containing such offices as the common of one martyr and bishop, the common of one martyr not a bishop, the common of many martyrs in paschal time, the common of many martyrs out of paschal time, and the like. A variety of masses to be used at the feast of the dedication of a church, of masses for the dead, and of votive masses (as for the sick, for persons journeying, for bridegroom and bride) follow, and also certain benedictions. Most missals have an appendix also containing certain local masses of saints to be celebrated "ex indulto apostolico."

---

[1] This was one of the points discussed at the council of Florence, and Cardinal Bessarion for a time succeeded in persuading the Greeks to give up the Epiklesis.

[2] Quam collectam dicunt, *Ord. Rom. II.*

[3] After singing "Credo in unum Deum," *Ord. Rom. II.*

Masses fall into two great subdivisions: (1) ordinary or regular (secundum ordinem officii), celebrated according to the regular rotation of fast and feast, vigil and feria, in the calendar; (2) extraordinary or occasional (extra ordinem officii), being either "votive" or "for the dead," and from the nature of the case having no definite time prescribed for them. Festival masses are either double, half-double or simple, an ordinary Sunday mass being a half-double. The difference depends on the number of collects and secretae; on a double only one of each is offered, on a half-double there are two or three, and on a simple there may be as many as five, or even seven, of each. Any mass may be either high (missa solennis) or low (missa privata). The distinction depends upon the number of officiating clergy, certain differences of practice as to what is pronounced aloud and what inaudibly, the use or absence of incense, certain gestures and the like. Solitary masses are forbidden; there must be at least an acolyte to give the responses. The vestments prescribed for the priest are the amice, alb, cingulum or girdle, maniple, stole and chasuble (planeta). There are certain distinctions of course for a bishop or abbot. The colour of the vestments and of the drapery of the altar varies according to the day, being either white, red, green, violet or black. This last custom does not go much further back than Innocent III., who explains the symbolism intended (see VESTMENTS).

Subjoined is an account of the manner of celebrating high mass according to the rite at present in force.

1. The priest who is to celebrate, having previously confessed (if necessary) and having finished matins and lauds, is to seek leisure for private prayer (fasting) and to use as he has opportunity the "prayers before mass" already referred to. How the robing in the sacristy is next to be gone about is minutely prescribed, and prayers are given to be used as each article is put on. The sacramental elements having previously been placed on the altar or on a credence table, the celebrant enters the church and takes his stand before the lowest step of the altar, having the deacon on his right and the subdeacon on his left. After invoking the Trinity (In nomine Patris, &c.) he repeats alternately with those who are with him the psalm "Judica me, Deus," which is preceded in the usual way by an antiphon (Introibo ad altare Dei), and followed also by the Gloria and Antiphon.[1] The versicle "Adjutorium nostrum," with its response "Qui fecit," is followed by the "Confiteor,"[2] said alternately by the priest and by the attendants, who in turn respond with the prayer for divine forgiveness, "Misereatur." The priest then gives the absolution ("Indulgentiam"), and after the versicles and responses beginning "Deus, tu conversus" he audibly says, "Oremus," and ascending to the altar silently offers two short prayers, one asking for forgiveness and liberty of access through Christ, and another indulgence for himself, "through the merits of the saints whose relics are here." Receiving the thurible from the deacon he censes the altar, and is thereafter himself censed by the deacon. He then reads the Introit, which is also sung by the choir; the *Kyrie eleison* is then said, after which the words *Gloria in excelsis*[3] are sung by the celebrant and the rest of the hymn completed by the choir.

2. Kissing the altar, and turning to the people with the formula "Dominus vobiscum," the celebrant proceeds with the collect or collects proper to the season or day, which are read secretly. The epistle for the day is then read by the subdeacon, and is followed by the gradual, tract, alleluia or sequence, according to the time.[4] This finished, the deacon places the book of the gospels on the altar, and the celebrant blesses the incense. The deacon kneels before the altar and offers the prayer "Munda cor meum," afterwards takes the book from the altar, and kneeling before the celebrant asks his blessing, which he receives with the words "Dominus sit in corde tuo." Having kissed the hand of the priest, he goes accompanied by acolytes with incense and lighted candles to the pulpit, and with a "Dominus vobiscum" and minutely prescribed crossings and censings gives out and reads the gospel for the day, at the close of which "Laus tibi, Christe" is said, and the book is brought to the celebrant and kissed with the words "Per evangelica dicta deleantur nostra delicta." The celebrant then standing at the middle of the altar sings the words "Credo in unum Deum," and the rest of the Nicene creed is sung by the choir.[5]

3. With "Dominus vobiscum" and "Oremus" the celebrant proceeds to read the offertory, which is also sung by the choir. This finished he receives the paten with the host from the deacon, and after offering the host with the prayer beginning "Suscipe, Sancte Pater" places it upon the corporal. The deacon then ministers wine and the subdeacon water, and before the celebrant mixes the water with the wine he blesses it in the prayer "Deus qui humanae." He then takes the chalice, and having offered it ("Offerimus tibi, Domine") places it upon the corporal and covers it with the pall. Slightly bowing over the altar, he then offers the prayer "In spiritu humilitatis," and, lifting up his eyes and stretching out his hands, proceeds with "Veni sanctificator." After blessing the incense ("Per intercessionem beati Michaelis archangeli") he takes the thurible from the deacon and censes the bread and wine and altar, and is afterwards himself censed as well as the others in their order. Next going to the epistle side of the altar he washes his fingers as he recites the verses of the 26th Psalm beginning "Lavabo." Returning and bowing before the middle of the altar, with joined hands he says, "Suscipe, sancta Trinitas," then turning himself towards the people he raises his voice a little and says, "Orate, fratres" ("that my sacrifice and yours may be acceptable to God the Father Almighty"), the response to which is "Suscipiat Dominus sacrificium de manibus tuis," &c. He then recites the secret prayer or prayers, and at the end says, with an audible voice, "Per omnia saecula saeculorum" (*R.* "Amen").

4. Again saluting with a "Dominus vobiscum," he lifts up his hands and goes on to the *Sursum corda* and the rest of the *Preface*. A different intonation is given for each of the prefaces.[6] At the Sanctus the handbell is rung. If there is a choir the *Sanctus* is sung while the celebrant goes on with the canon.[7] After the words of consecration of the wafer, which are said "secretly, distinctly and attentively," the celebrant kneels and adores the host, rising elevates it, and replacing it on the corporal again adores

---

[1] This antiphon is not to be confounded with the Antiphona ad Introitum further on. This use of the 43rd Psalm goes as far back at least as the end of the 11th century, being mentioned by Micrologus (1080). It is omitted in masses for the dead and during Holy Week.

[2] A form very similar to the present is given by Micrologus, and it is foreshadowed even in liturgical literature of the 8th century.

[3] During Lent and Advent, and in masses for the dead, this is omitted. In low masses it is of course said, not sung (if it is to be said). It may be added that this early position of the *Gloria in excelsis* is one of the features distinguishing Roman from Ephesine use.

[4] The tract is peculiar to certain occasions, especially of a mournful nature, and is sung by a single voice. By a sequence is understood a more or less metrical composition, not in the words of Scripture, having a special bearing on the festival of the day. See, for example, the sequence, "Lauda Sion Salvatorem," on Corpus Christi day.

[5] On certain days the *Credo* is omitted.

[6] Now eleven; they were at one time much more numerous.

[7] The approved usage appears to be in that case that it is sung as far as "Hosanna in excelsis" before the elevation, and "Benedictus qui venit" is reserved till afterwards. In France it was a very common custom, made general for a time at the request of Louis XII., to sing "O salutaris hostia" at the elevation.

it (the bell meanwhile being rung).[1] The same rite is observed when the chalice is consecrated. Immediately before the Lord's Prayer, at the words " per ipsum et cum ipso et in ipso," the sign of the cross is made three times over the chalice with the host, and towards the close of the " embolism " the fraction of the host takes place. After the words " Pax Domini sit semper vobiscum " the emission of the particle into the cup takes place with the words " Haec commixtio et consecratio," &c. The celebrant then says the *Agnus Dei* three times.

5. While the choir sings the *Agnus Dei* and the Communion, the celebrant proceeds, still " secrete," with the remainder of the office, which though printed as part of the canon is more conveniently called the communion and post-communion. After the prayer for the peace and unity of the Church (" Domine Jesu Christe, qui dixisti ") he salutes the deacon with the kiss of peace, saying, " Pax tecum "; the subdeacon is saluted in like manner, and then conveys the " pax " to the rest of the clergy who may be assisting. The celebrant then communicates under both species with suitable prayers and actions, and afterwards administers the sacrament to the other communicants if there be any. Then while the wine is poured into the cup for the first ablution he says, " Quod ore sumpsimus "; having taken it he says, " Corpus tuum, Domine." After the second ablution he goes to the book and reads the Communion. Then turning to the people with " Dominus vobiscum " he reads the post-communion (one or more); turning once more to the congregation he uses the old dismissal formula " Dominus vobiscum " (*R.* " Et cum spiritu tuo "), and " Ite, missa est " or " Benedicamus Domino," in those masses from which *Gloria in excelsis* has been omitted (*R.* " Deo Gratias "). Bowing down before the altar he offers the prayer " Placeat tibi, sancta Trinitas," then turning round he makes the sign of the cross over the congregation with the words of the benediction (" Benedicat ").[2] He then reads the passage from the gospel of John beginning with " In principio erat Verbum," or else the proper gospel of the day.[3] (J. S. Bl.)

MISSI DOMINICI, the name given to the officials commissioned by the Frankish kings and emperors to supervise the administration of their dominions. Their institution dates from Charles Martel and Pippin the Short, who sent out officials to see their orders executed. When Pippin became king in 754 he sent out *missi* in a desultory fashion; but Charlemagne made them a regular part of his administration, and a *capitulary* issued about 802 gives a detailed account of their duties. They were to execute justice, to enforce respect for the royal rights, to control the administration of the counts, to receive the oath of allegiance, and to supervise the conduct and work of the clergy. They were to call together the officials of the district and explain to them their duties, and to remind the people of their civil and religious obligations. In short they were the direct representatives of the king or emperor. The inhabitants of the district they administered had to provide for their subsistence, and at times they led the host to battle. In addition special instructions were given to various *missi*, and many of these have been preserved. The districts placed under the *missi*, which it was their duty to visit four times a year, were called *missatici* or *legationes*. They were not permanent officials, but were generally selected from among persons at the court, and during the reign of Charlemagne personages of high standing undertook this work. They were sent out in twos, an ecclesiastic and a layman, and were generally complete strangers to the district which they administered. In addition there were extraordinary *missi* who represented the emperor on special occasions, and at times beyond the limits of his dominions. Even under the strong rule of Charlemagne it was difficult to find men to discharge these duties impartially, and after his death in 814 it became almost impossible. Under the emperor Louis I. the nobles interfered in the appointment of the *missi*, who, selected from the district in which their duties lay, were soon found watching their own interests rather than those of the central power. Their duties became merged in the ordinary work of the bishops and counts, and under the emperor Charles the Bald they took control of associations for the preservation of the peace. About the end of the 9th century they disappeared from France and Germany, and during the 10th century from Italy. It is possible that the itinerant justices of the English kings Henry I. and Henry II., the itinerant *baillis* of Philip Augustus king of France, or the royal *enquêteurs* of St Louis originated from this source.

Beauchet, *Histoire de l'organization judiciaire en France, époque franque* (Paris, 1865).

MISSIONS (Lat. *missio*, a sending) the term used specially for the propagandist operations of the Christian Church among the heathen, the executants of this work being missionaries. Both " mission " and " missionary " have hence come to be used of similar works in other spheres. The history of Christian missions may, for practical purposes, be divided into three chief periods: (1) the primitive, (2) the medieval and (3) the modern.

The Primitive Period

There can be little doubt that the Christian Church derived its missionary impulse from the teaching of its founder. Even though we may feel some hesitancy, in the light of modern criticism, about accepting as authentic the specific injunctions ascribed to Jesus by Matthew (ch. xxviii. 19) and Luke (ch. xxiv. 47; Acts i. 8), it must be admitted that the teaching of Jesus, in the emphasis which it laid on the Fatherhood of God and the brotherhood of man, was bound sooner or later to break away from the trammels of Judaism, and assert itself in the form of Christian missions. The triumph of this " universalistic " element in the teaching of Christ is vividly portrayed in the Acts of the apostles. At the beginning of the Acts the Christian Church is a little Jewish sect; long before the end is reached it has become a world-conquering spiritual force. The transformation was due in its initial stages to broad-minded men like Stephen, Philip and Barnabas who were the first pioneers of missionary work. Their efforts, however, were soon completely eclipsed by the magnificent achievements of the apostle Paul, who evangelized a large part of Asia Minor and the most important cities of Greece. The success which attended the work of the great apostle to the Gentiles stamped Christianity as a missionary religion for ever. From this point onwards Christianity pushed its way into all the great centres of population. We know very little about the missionaries of the first three centuries. We suddenly find province after province christianized though there is nothing to show how and by whom the work was done. The case of Bithynia is an excellent illustration of this. When Pliny wrote his famous letter to Trajan (A.D. 112), Christianity had taken such a firm hold of the province that its influence had penetrated into remote country districts, pagan festivals were almost entirely neglected, and animals for sacrifice could scarcely find purchasers. Yet the history of the conversion of Bithynia is absolutely buried in oblivion. By the time of Constantine, Christianity had practically covered the whole empire. Harnack has tabulated the results which our scanty data allow us to reach in his *Expansion of Christianity*. He divides the countries which had been evangelized by the close of the 3rd century into four groups: (1) Those countries in which Christianity numbered nearly one-half of the population and represented the standard religion of the people, viz. most of what we now call Asia Minor, that portion of Thrace which lay over against Bithynia, Armenia, the city of Edessa. (2) Those districts in which Christianity formed a very material portion of the population, influencing the leading classes and being able to hold its own with other religions, viz. Antioch and Coele-Syria, Cyprus, Alexandria together with Egypt and the Thebais, Rome and the lower parts of Italy, together with certain parts of middle Italy, Proconsular Africa and Numidia, Spain, the maritime parts of Greece, the southern coasts of Gaul.

---

[1] The history of the practice of elevating the host seems to have arisen out of the custom of holding up the oblations, as mentioned in the *Ordo Romanus* (see above). The elevation of the host, as at present practised, was first enjoined by Pope Honorius III. The use of the handbell at the elevation is still later, and was first made general by Gregory XI.

[2] The benediction is omitted in masses for the dead.

[3] The reading of the passage from John on days which had not a proper gospel was first enjoined by Pius V.

(3) Those districts in which Christianity was sparsely scattered, viz. Palestine, Phoenicia, Arabia, certain parts of Mesopotamia, the interior districts of Greece, the provinces on the north of Greece, the northern districts of middle Italy, the provinces of Mauretania and Tripolis. (4) Those districts in which Christianity was extremely weak or where it was hardly found at all: the districts to the north and north-west of the Black Sea, the western section of upper Italy, middle and upper Gaul, Belgica, Germany, Rhaetia, the towns of ancient Philistia. It is not possible to obtain even an approximate estimate of the numbers of the Christians at the time of Constantine. Friedländer, for instance, does not think that they exceeded by much Gibbon's estimate for the reign of Decius, viz. one-twentieth of the population. La Bastie and Burckhardt put the ratio at one-twelfth, Matter at a fifth and Stäudlin even at a half (see Harnack ii. 453).

After the end of the 3rd century missionary enterprise was mainly concentrated on the outlying borders of the empire. In the 4th and 5th centuries may be mentioned Gregory the Illuminator, the "apostle of Armenia" (about 300), Ulfilas, the "apostle of the Goths," about 325; Frumentius,[1] a bishop of Abyssinia, about 327; Nino, the Armenian girl who was the means of converting the kingdom of Iberia (now Georgia), about 330;[2] Chrysostom, who founded at Constantinople in A.D. 404 an institution in which Goths might be trained to preach the Gospel to their own people;[3] Martin of Tours, who evangelized the central districts of Gaul; Valentinus, the "apostle of Noricum," about 440; Honoratus, who from his monastic home in the islet of Lerins, about 410, sent missionaries among the masses of heathendom in the neighbourhood of Arles, Lyons, Troyes, Metz and Nice; and St Patrick, who converted Ireland into "the isle of saints" (died either in 463 or 495).

The Medieval Period

With the 5th century the Church was confronted with numberless hordes, which were now precipitated over the entire face of Europe. Having for some time learnt to be aggressive, she girded herself for the difficult work of teaching the nations a higher faith than a savage form of nature-worship, and of fitting them to become members of an enlightened Christendom.

(*a*) *The Celtic Missionaries.*—The first pioneers who went forth to engage in this difficult enterprise came from the secluded Celtic Churches of Ireland and the Scottish Highlands. Of many who deserve mention in connexion with this period, the most prominent were: Columba, the founder of the famous monastery of Iona in 563 and the evangelizer of the Albanian Scots and northern Picts; Aidan, the apostle of Northumbria; Columbanus, the apostle of the Burgundians of the Vosges (590); Callich or Gallus (d. 646), the evangelizer of north-eastern Switzerland and Alemannia; Kilian, the apostle of Thuringia; and Trudpert, the martyr of the Black Forest. The zeal of these men seemed to take the world by storm. Travelling generally in companies, and carrying a simple outfit, these Celtic pioneers flung themselves on the continent of Europe, and, not content with reproducing at Annegray or Luxeuil the willow or brushwood huts, the chapel and the round tower, which they had left behind in Derry or in the island of Hy (Iona), they braved the dangers of the northern seas, and penetrated as far as the Faroes and even far distant Iceland.[4] "Their zeal and success," to quote the words of Kurtz, "are witnessed to by the fact that at the beginning of the 8th century, throughout all the district of the Rhine, as well as Hesse, Thuringia, Bavaria and Alemannia, we find a network of flourishing churches bearing the impress of Celtic institutions."

(*b*) *The English Missionaries.*—Thus they laid the foundations, aweing the heathen tribes by their indomitable spirit of self-sacrifice and the sternness of their rule of life. But, marvellous as it was, their work lacked the element of permanence; and it became clear that a more practical system must be devised and carried out. The men for this work were now ready, and the sons of the newly evangelized English Churches were ready to go forth. The energy which warriors were accustomed to put forth in their efforts to conquer was now "exhibited in the enterprise of conversion and teaching"[5] by Wilfrid on the coast of Friesland,[6] by Willibrord (658–715) in the neighbourhood of Utrecht,[7] by the martyr-brothers Ewald or Hewald amongst the "old" or continental Saxons,[8] by Swidbert the apostle of the tribes between the Ems and the Yssel, by Adelbert, a prince of the royal house of Northumbria, in the regions north of Holland, by Wursing, a native of Friesland, and one of the disciples of Willibrord, in the same region, and last, not least, by the famous Winfrid or Boniface, the "apostle of Germany" (680–755), who went forth first to assist Willibrord at Utrecht, then to labour in Thuringia and Upper Hessia, then with the aid of his kinsmen Wunibald and Willibald, their sister Walpurga, and her thirty companions, to consolidate the work of earlier missionaries, and finally to die a martyr on the shore of the Zuider Zee.

(*c*) *Scandinavian Missions.*—Devoted, however, as were the labours of Boniface and his disciples, all that he and they and the emperor Charlemagne after them achieved for the fierce untutored world of the 8th century seemed to have been done in vain when, in the 9th "on the north and north-west the pagan Scandinavians were hanging about every coast, and pouring in at every inlet; when on the east the pagan Hungarians were swarming like locusts and devastating Europe from the Baltic to the Alps; when on the south and south-east the Saracens were pressing on and on with their victorious hosts. It seemed then as if every pore of life were choked, and Christendom must be stifled and smothered in the fatal embrace."[9] But the devoted Anskar (801–865) went forth and sought out the Scandinavian viking, and handed on the torch of self-denying zeal to others, who saw, after the lapse of many years, the close of the monotonous tale of burning churches and pillaged monasteries, and taught the fierce Northman to learn respect for civilized institutions.[10] The gospel was first introduced into Norway in the 10th century by an Englishman named Hacon, though the real conversion of the country was due to Olaf Tryggvasön. About the same time, and largely owing to the exertions of Olaf, Iceland, Greenland and the Orkney and Shetland islands were also evangelized.

(*d*) *Slavonic Missions.*—Thus the "gospel of the kingdom" was successively proclaimed to the Roman, the Celtic, the Teutonic and the Scandinavian world. A contest still more stubborn remained with the Slavonic tribes, with their triple and many-headed divinities, their powers of good and powers of evil, who could be propitiated only with human sacrifices. Mission work commenced in Bulgaria during the latter part of the 9th century; thence it extended to Moravia, where in 863 two Greek missionaries—Cyril and Methodius—provided for the people a Slavonic Bible and a Slavonic Liturgy; thence to Bohemia and Poland, and so onwards to the Russian kingdom of Ruric the Northman, where about the close of the 10th century the Eastern Church "silently and almost unconsciously bore into the world her mightiest offspring."[11] But, though the baptism of Vladimir (*c.* 956–1015) was a heavy blow to Slavonic idolatry, mission work was carried on with but partial success; and it taxed all the energies of Adalbert, bishop of Bremen, of Vicilin, bishop of Oldenburg, of Bishop Otto of Bamberg the apostle of the Pomeranians, of Adalbert the martyr-apostle of Prussia, to spread the word in that country, in Lithuania, and in the territory of the Wends. It was not till 1168 that the gigantic four-headed image of Swantevit was destroyed at Arcona, the capital of the island of Rügen, and this Mona of Slavonic superstition was included in the advancing circle of Christian civilization. As late as 1230 human sacrifices were still being offered up in Prussia and Lithuania, and, in spite of all the efforts of the Teutonic Knights, idolatrous practices still lingered amongst the people, while amongst the Lapps, though successful missions had been inaugurated as early as 1335, Christianity cannot be said to have become the dominant religion till at least two centuries later.

(*e*) *Moslem Missions.*—The mention of the order of the Teutonic Knights reminds us how the crusading spirit had affected Christendom. Still even then Raimon Lull protested against propagandism by the sword, urged the necessity of missions amongst the Moslems, and sealed his testimony with his blood outside the gates of Bugiah in northern Africa (June 30, 1315). Out of the crusades, however, arose other efforts to develop the work which Nestorian missionaries from Bagdad, Edessa and Nisibis had already inaugurated along the Malabar coast, in the island of Ceylon, and in the neighbourhood of the Caspian Sea. In 1245 the Roman pontiff sent two embassies—one, a party of four Dominicans, sought the commander-in-chief of the Mongol forces in Persia; the second, consisting of Franciscans, made their way into Tartary, and sought to convert the successor of Oktai-Khan. Their exertions were seconded in 1253 by the labours of another Franciscan whom Louis IX. of France sent forth from Cyprus,[1] while in 1274 the celebrated traveller Marco Polo, accompanied by two learned Dominicans, visited the court of Kublai-Khan, and at the commencement of the 14th century two Franciscans penetrated as far as Peking, even translating the New Testament and the Psalter into the Tatar language, and training youths for a native ministry.[2]

(*f*) *Missions to India and the New World.*—These tentative missions were now to be supplemented by others on a larger scale. In 1488 the Cape of Good Hope was rounded by Diaz, and in 1508 the foundations of the Portuguese Indian empire were laid by Albuquerque. Columbus also in 1492 had landed on San Salvador, and the voyages of the Venetian Cabot along the coast of North America opened up a new world to missionary enterprise. Thus a grand opportunity was given to the churches of Portugal and Spain. But the zeal of the Portuguese took too often a one-sided direction, repressing the Syrian Christians on the Malabar coast, and interfering with the Abyssinian Church,[3] while the fanatic temper of the Spaniard consigned, in Mexico and Peru, multitudes who would not renounce their heathen errors to indiscriminate massacre or abject slavery.[4] Las Casas has drawn a terrible picture of the oppression he strove in vain to prevent.[5] Some steps indeed were taken for disseminating Christian principles, and the pope had induced a band of missionaries, chiefly of the mendicant orders, to go forth to this new mission field.[6] But only five bishoprics had been established by 1520, and the number of genuine converts was small. However, every vestige of the Aztec worship was banished from the Spanish settlements.[7]

(*g*) *The Jesuit Missions.*—It was during this period that the Jesuits came into existence. One of the first of Loyola's associates, Francis Xavier, encouraged by the joint co-operation of the pope and of John III. of Portugal, disembarked at Goa on the 6th of May 1542, and before his death on the Isle of St John (Hiang-Shang), on the 2nd of December 1552, roused the European Christians of Goa to a new life, laboured with singular success amongst the Paravars, a fisher caste near Cape Comorin, gathered many converts in the kingdom of Travancore, visited Malacca, and founded a mission in Japan.

The successor of Xavier, Antonio Criminalis, was regarded by the Jesuits as the first martyr of their society (1562). Matteo Ricci, an Italian by birth, was also an indefatigable missionary in China for twenty-seven years, while the unholy compromise with Brahminism in India followed by Robert de' Nobili was fatal to the vitality of his own and other missions. Others of the same order evangelized Paraguay in 1582, while the Huguenots sent forth under a French knight of Malta a body of devoted men to attempt the formation of a Christian colony at Rio Janeiro. By the close of the 16th century a committee of cardinals was appointed under the name of the "Congregatio de propaganda fide," to give unity and solidity to the work of missions. The scheme originated with Gregory XIII., but was not fully organized till forty years afterwards, when Gregory XV. gave it plenary authority by a bull dated the 2nd of June 1622. Gregory's successor, Urban VIII., supplemented the establishment of the congregation by founding a great missionary college, where Europeans might be trained for foreign labours, and natives might be educated to undertake mission work. At this college is the missionary printing-press of the Roman Church, and its library contains an unrivalled collection of literary treasures bearing on the work.

MODERN MISSIONS

Missionary Societies.—Modern missionary activity is distinguished in a special degree by the exertions of societies for the development of mission work.

As contrasted with the colossal display of power on the part of the Church of Rome, it must be allowed that the churches which in the 16th century broke off from their allegiance to the Latin centre at first showed no great anxiety for the extension of the gospel and the salvation of the heathen. The causes of this are not far to seek. The isolation of the Teutonic churches from the vast system with which they had been bound up, the conflicts and troubles among themselves, the necessity of fixing their own principles and defining their own rights, concentrated their attention upon themselves and their own home work, to the neglect of work abroad.[8]

Still the development of the maritime power of England, which the Portuguese and Spanish monarchies noted with fear and jealousy, was distinguished by a singular anxiety for the spread of the Christian faith. Edward VI. in his instructions to the navigators in Sir Hugh Willoughby's fleet, Sebastian Cabot in those for the direction of the intended voyage to Cathay, and Richard Hakluyt, who promoted many voyages of discovery in addition to writing their history, agree with Sir Humphrey Gilbert's chronicler that "the sowing of Christianity must be the chief intent of such as shall make any attempt at foreign discovery, or else whatever is builded upon other foundation shall never obtain happy success or continuance." When on the last day of the year 1600 Queen Elizabeth granted a charter to George, earl of Cumberland, and other "adventurers," to be a body-corporate by the name of "The Governor and Company of Merchants of London trading with the East Indies," the expressed recognition of higher duties than those of commerce may by some be deemed a mere matter of form, and, to use the words of Bacon, "what was first in God's providence was but second in man's appetite and intention." Yet a keen sense of missionary duty marks many of the chronicles of English mariners. Notably was this the case with the establishment of the first English colony in America, that of Virginia, by Sir Walter Raleigh. The philosopher Thomas Harriot (1560–1621), one of his colleagues, laboured for the conversion of the natives, amongst whom the first baptism is recorded to have taken place on the 13th of August 1587.[9] Raleigh himself presented as a parting gift to the Virginian Company the sum of £100 "for the propagation of the Christian religion" in that settlement.[10] When James I. granted letters patent for the occupation of Virginia it was directed that the "word and service of God be preached, planted and used as well in the said colonies as also as much as might be among the savages bordering among them"; and the honoured names of Nicolas Ferrar, John Ferrar, John Donne and Sir John Sandys, a pupil of Hooker, are all found on the council by which the home management of the colony was conducted.

[10] Oldy, *Life of Raleigh*, p. 118.

In the year 1618 was published *The True Honour of Navigation and Navigators*, by John Wood, D.D., dedicated to Sir Thomas Smith, governor to the East India Company, and about the same time appeared the well-known treatise of Hugo Grotius, *De veritate religionis christianae*, written for the express use of settlers in distant lands. Grotius also persuaded seven law students of Lübeck to go to the East as missionaries; the best known of them was Peter Heiling, who worked for 20 years in Abyssinia. A good deal of work was done by Dutch evangelists in Java, the Moluccas, Formosa and Ceylon, but it was not permanent.

The wants, moreover, of the North American colonies did not escape the attention of Archbishop Laud during his official connexion with them as bishop of London, and he was developing a plan for promoting a local episcopate there when his troubles began and his scheme was interrupted. During the Protectorate, in 1649, an ordinance was passed for "the promoting and propagating of the gospel of Jesus Christ in New England" by the erection of a corporation, to be called by the name of the President and Society for the Propagation of the Gospel in New England, to receive and dispose of moneys for the purpose, and a general collection was ordered to be made in all the parishes of England and Wales; and Cromwell himself devised a scheme for setting up a council for the Protestant religion, which should rival the Roman Propaganda, and consist of seven councillors and four secretaries for different provinces.[1] On the restoration of the monarchy, through the influence of Richard Baxter with Lord Chancellor Hyde, the charter already granted by Cromwell was renewed, and its powers were enlarged. For now the corporation was styled "The Propagation of the Gospel in New England and the parts adjacent in America," and its object was defined to be "not only to seek the outward welfare and prosperity of those colonies, but more especially to endeavour the good and salvation of their immortal souls, and the publishing the most glorious gospel of Christ among them." On the list of the corporation the first name is the earl of Clarendon, while the Hon. Robert Boyle was appointed president. Amongst the most eminent of its missionaries was the celebrated John Eliot, the Puritan minister of Roxbury, Massachusetts, who, encouraged and financially assisted by Boyle, brought out the Bible in the Indian language in 1661–1664. Boyle displayed in other ways his zeal for the cause of missions. He contributed to the expense of printing and publishing at Oxford the four Gospels and the Acts of the Apostles in the Malay language, and at his death left £5400 for the propagation of the gospel in heathen lands.

The needs of the colonial church soon excited the attention of others. George Fox, the Quaker, wrote to "All Friends everywhere that have Indians or blacks, to preach the Gospel to them and their servants." Great efforts were made by William Beveridge (1637–1708), bishop of St Asaph, William Wake (1657–1737), archbishop of Canterbury, John Sharp (1645–1714), archbishop of York, Edmund Gibson (1669–1748), bishop of London, and afterwards by the philosophic Bishop Berkeley, and Bishop Butler, the famous author of the *Analogy*, to develop the colonial church and provide for the wants of the Indian tribes. In 1696 Dr Thomas Bray, at the request of the governor and assembly of Maryland, was selected by the bishop of London as ecclesiastical commissary; and, having sold his effects, and raised money on credit, he sailed for Maryland in 1699, where he promoted, in various ways, the interests of the Church. Returning to England in 1700–1701, and supported by all the weight of Archbishop Tenison and Henry Compton, bishop of London, he was graciously received by William III., and received letters patent under the great seal of England for creating a corporation by the name of the "Society for the Propagation of the Gospel in Foreign Parts" on the 16th of June 1701.

Meanwhile, in 1664, Von Welz, an Austrian baron, issued a stirring appeal to the Church at large for a special association devoted to extending the evangelical religion and converting the heathen. He was told that each Christian country should be responsible for its non-Christian neighbours, *e.g.* the Greeks for the Turks, and that as for the heathen it was no good casting pearls before swine. Finding no better response, he went himself as a missionary to Dutch Guiana. The opening of the 18th century saw other movements set on foot. Thus in 1705 Frederick IV. of Denmark founded a mission on the Coromandel coast, and inaugurated the labours of Bartholomew Ziegenbalg, Henry Plutschau and C. F. Schwartz, whose devotion and success told with such remarkable reflex influence on the Church at home. Again in 1731 the Moravians (*q.v.*) illustrated in a signal degree the growing consciousness of obligation towards the heathen. Driven by persecution from Moravia, hunted into mountain-caves and forests, they had scarcely secured a place of refuge in Saxony before, "though a mere handful in numbers, yet with the spirit of men banded for daring and righteous deeds, they formed the heroic design, and vowed the execution of it before God, of bearing the gospel to the savage and perishing tribes of Greenland and the West Indies, of whose condition report had brought a mournful rumour to their ears." And so, literally with "neither bread nor scrip," they went forth on their pilgrimage, and, incredible as it sounds, within ten years they had established missions in the islands of the West Indies, in South America, Surinam, Greenland, among the North American tribes, in Lapland, Tartary, Algiers, Guinea, the Cape of Good Hope and Ceylon.[2] Up till this time all missionary enterprises had been more or less connected with the state. The era of modern missions, based on associate organizations, begins with William Carey (*q.v.*), and is closely connected with the great evangelical revival of the latter part of the 18th century. That revival had intensified the idea of the worth of the individual soul, whether Christian or heathen, and "to snatch even one brand from the burning" became a dominant impulse. In 1792, Carey, a Baptist, who was not only a cobbler, but a linguist of the highest order, a botanist and zoologist, published his *Enquiry into the Obligations of Christians to use Means for the Conversion of the Heathens*, and the book marks a distinct point of departure in the history of Christianity. Under its influence twelve ministers at Kettering in October 1792 organized the Baptist Society for Propagating the Gospel among the Heathen, and subscribed £13, 2s. 6d. In June 1793 Carey was on his way to India. Letters from him quickened interest outside his own communion, and in the autumn of 1794 a meeting of Evangelical ministers of all denominations resolved to appeal to their churches, especially with a view to work being started in the South Sea Islands. The chief movers in the enterprise were the Congregationalist, David Bogue of Gosport, and the Episcopalian, Thomas Haweis, rector of Aldwinkle, Northamptonshire. With them were associated Wesleyan and Presbyterian divines, and in September 1795 the London Missionary Society, emphasizing no one form of church government, was formed. £10,000 was subscribed by June 1796, and in August 29 missionaries sailed for Tahiti. Societies formed in Glasgow and Edinburgh in the spring of the same year gave their attention to the continent of Africa.

The need of this continent was also the means of creating the distinctively Anglican organization known as the Church Missionary Society. The evangelical movement had produced philanthropists like Wilberforce and Granville Sharp, and the Eclectic Society, a group of clergy and laymen who fell to discussing the new missionary movements. In April 1799, under the guidance of John Venn and Thomas Scott, was established the Church Missionary Society, originally known as the "Society for Missions to Africa and the East." Its promoters declared their intention of maintaining cordial relations with Nonconformist missionary societies, and this has largely been done, the older Society for the Propagation of the Gospel, manned by "High" Churchmen, standing more aloof. In 1814 the Wesleyan Missionary Society was formed, Methodist effort of this kind having previously been left to the individual enterprise of Dr Thomas Coke. Thus shorn of two chief bodies of supporters, and Presbyterians in England being then comparatively few, the London Missionary Society became in effect a Congregationalist organization, though it has never departed from the broad spirit of its founders. In Scotland Robert Haldane sold his estate and devoted £25,000 to the cause; with others he would have gone to India himself but for the prohibition of the East India Company, one of whose directors said he would rather see a band of devils in India than a band of missionaries. What Carey did for England was largely done for Scotland by Alexander Duff, who settled in Calcutta in 1830, and was a pioneer of higher education in India. On the Continent the Basel Mission (1815) grew out of a society founded in 1780 to discuss the general condition of Christianity; "Father" Jänicke, a Bohemian preacher in Berlin, founded a training school which supplied many men to the Church Missionary Society and the London Missionary Society; and Van der Kemp, who pioneered the London Missionary Society work in South Africa, organized in 1797 the Netherland Missionary Society, which turned its attention chiefly to Dutch Colonial possessions.

In America as in England the sense of individual responsibility had been developed. In 1796 and 1797 respectively the New York and the Northern societies were formed for work among Indians by Presbyterians, Baptists and Reformed Dutch, acting in concert. News of the London Society stimulated interest in New England, and in 1806 Andover Seminary was founded as a missionary training college. In the same year Samuel J. Mills, Gordon Hall and James Richards, three students at Williams College, Massachusetts, formed themselves into a mission band which ultimately became the American Board of Commissioners for Foreign Missions (June 1810), an organization which, like the London Mission, originally undenominational and still catholic, has become practically Congregational. The first offshoot from it was the American Baptist Missionary Union in 1814.

The following chronological lists illustrate the growth of missionary societies in Britain and the United States:—

Great Britain and Ireland.

1691. Christian Faith Society for the West Indies.
1698 Society for Promoting Christian Knowledge.
1701 Society for the Propagation of the Gospel in Foreign Parts.
1732. Moravian Missions.
1792. Baptist Missionary Society.
1795. London Missionary Society.
1796. Scottish Missionary Society.
1799. Church Missionary Society.
1799. Religious Tract Society.
1804. British and Foreign Bible Society.
1808. London Society for Promoting Christianity among the Jews.
1813. Wesleyan Missionary Society.
1817. General Baptist Missionary Society.
1823. Colonial and Continental Church Society.
1825. Church of Scotland Mission Boards.
National Bible Society of Scotland.
1831. Trinitarian Bible Society.
1832. Wesleyan Ladies' Auxiliary for Female Education in Foreign Countries.
1835. United Secession (afterwards United Presbyterian) Foreign Missions.
1836. Colonial Missionary Society.
1840. Irish Presbyterian Missionary Society.
1840. Welsh Calvinistic Methodist Missionary Society.
1841. Colonial Bishoprics Fund.
1841. Edinburgh Medical Missionary Society.
1843. British Society for the Propagation of the Gospel among the Jews.
1843. Free Church of Scotland Missions.
1843. Primitive Methodist African and Colonial Missions.
Methodist New Connexion in England Foreign Missions.
1844. South American Missionary Society.
1847. Presbyterian Church in England Foreign Missions.
1858. Christian Vernacular Education Society for India.
1860. Central African Mission of the English Universities.
1862. China Inland Mission.
1865. Friends' Foreign Mission Association.
1866. Delhi Female Medical Mission.
1867. Friends' Mission in Syria and Palestine.
1876. Cambridge Mission to Delhi.
1880. Church of England Zenana Missionary Society.
1884. Presbyterian Mission to Korea.
1892. Student Volunteer Missionary Union.

United States of America.

1733. Corporation for the Propagation of the Gospel in New England.
1787. Society for Propagating the Gospel among the Indians at Boston.
1795. Friends' Missionary Society.
1800. New York Missionary Society.
Connecticut Missionary Society for Indians.
1803. United States Mission to the Cherokees.
1806. Western Missionary Society for Indians.
1810. Board of Commissioners for Foreign Missions.
1814. Baptist Missionary Union.
1819. Methodist Episcopal Church Missionary Society.
1833. Free-will Baptist Foreign Missionary Society in India.
1835. Foreign Missions of the Protestant Episcopal Church.
1837. Board of Foreign Missions of the Presbyterian Church (North).
1837. Evangelical Lutheran Foreign Missionary Society.
1842. Seventh Day Baptist Missionary Society.
Strict Baptist Missionary Society.
1843. Baptist Free Missionary Society.
1845. Methodist Episcopal Church (South).
1845. Southern Baptist Convention.
1846. American Missionary Association.
1857. Board of Foreign Missions of (Dutch) Reformed Church.
1859. Board of Foreign Missions of United Presbyterian Church.
1862. Board of Foreign Missions of the Presbyterian Church (South).
1878. Evangelical Association Missionary Society.
1886. Student Volunteer Missionary Union.

It is not possible to follow in detail the history of the hundred or more organized societies of some size that have thus come into being since the end of the 18th century, still less that of the three or four hundred smaller agencies.[1] It may be noted, however, that the enterprise has followed certain more or less clearly defined lines. These are described as follows by Dr E. M. Bliss, editor of the *Encyclopaedia of Missions.*

1. *The Denominational.*—The course of denominational work may be seen in the way in which the London Society and the American Board were gradually left to the Congregationalists, it being recognized that while fraternity was maintained, the widest results could only be obtained as appeal was made directly to the members of each separate denomination. To some extent a similar development is traceable in other lands. In Germany the Rhenish Society (1825) became independent of the Basel Mission, but like it and the Berlin Society founded by Neander and Tholuck has preserved a broad basis and includes both Lutheran and Reformed constituents. The North German or Bremen Society split into a strict Lutheran or Leipzig agency and the Hermannsburg Mission, which aimed at a more primitive and apostolic method. In Denmark, the Danish Missionary Society, founded by Pastor Bone Falck Ronne in 1821, worked through the Moravian and Basel societies until 1862, when it began independent work and concentrated on the Tamil population of South India. In Norway and Sweden missionary activity kept pace with the development of the national life; in the former country the Free Church, in the latter the State Church has been the most successful agency.

In Holland a religious revival in 1846 led to the foundation of several organizations which supplemented the work of the original Netherland Missionary Society. In France protestant missionary effort began after the overthrow of the empire, and in 1822 several isolated committees united to form the Société des Missions Évangéliques, better known as the Paris Evangelical Society. In Tahiti, Madagascar and other fields this society has largely taken over work begun by the London Society, whose operations were viewed with suspicion by the French government.

2. *Collateral Aid.*—Side by side with the founding of the great missionary societies, Bible and Tract societies sprang up. The dates are significant: Society for Promoting Christian Knowledge (1698), Religious Tract and Book Society of Scotland (1793), Religious Tract Society in London (1799), British and Foreign Bible Society (1804), American Bible Society (1816), American Tract Society (1823). (See further BIBLE SOCIETIES.) Medical Missions have not been so much collateral organizations as departments of the work of the general societies, and the same is generally true of women's missions. Both of these will be discussed in more detail.

3. *Independent and Special Agencies.*—The individual element that was so marked a feature in Carey's generation has never vanished, in spite of the tendency to central control. J. Hudson Taylor in 1853 went to China as the agent of a number of folk in England who feared that missionary work was becoming too mechanical. His aim was to push inland and to work through native evangelists. Out of his endeavours sprang a new organization, the China Inland

---

Mission; and similar undenominational societies, *e.g.* the Regions Beyond Missionary Union in England, and the Christian and Missionary Alliance in America, have since been founded. Other individual enterprises have been launched by persons or single churches, but such have not usually flourished for any length of time, their workers gradually attaching themselves to the larger associations.

I. British.

Protestant Missions.—It is generally agreed that the period since 1885 has witnessed a very marked increase of missionary zeal and interest in Great Britain, both in the Church of England and among the Nonconformists. The improvement, indeed, dates back somewhat earlier. So far as the Church of England is concerned it may fairly be said to have started afresh in the year following the first observance of the Day of Intercession for Missions, on the 20th of December 1872. Both the Society for the Propagation of the Gospel and the Church Missionary Society were at that time suffering from a general coldness which, in the case of the latter society, had led in that very year to the committee reporting "a failing treasury and a scanty supply of men." The observance of that first Day of Intercession was followed by an immediate change, and unquestionably there has been progress ever since. Then, less than five months afterwards, David Livingstone died at Ilala; and no event of the whole century did so much to wake up Protestant Christendom. Most of the missions in Central Africa owe their origin to the spirit it aroused. But the year 1884 was also an epoch to be marked. In that year Bishop Hannington went to Africa; and his murder in 1885 (first reported in England on New Year's Day, 1886) deeply touched the Christian conscience. The speedy publication of E. C. Dawson's biography of him worked a revolution in the circulation of missionary literature. Another event of 1884–1885 was the going forth to China of "The Cambridge Seven," in connexion with the China Inland Mission. All were men of good family; some of them went at their own charges; and among them were the stroke-oar of the University Eight (Mr Stanley Smith) and the captain of the University Eleven (Mr C. T. Studd). Probably no event of recent years has exercised a wider influence in the cause of missions. In particular, university graduates have since then gone out as missionaries in much larger numbers than before. There are now five missions definitely linked with the universities. The Central African Mission (1858), indeed, is not for the most part manned by graduates, though it is led by them; but the Cambridge Mission at Delhi (1878), the Oxford Mission at Calcutta (1880), and the Dublin Missions in Chota Nagpur (Society for the Propagation of the Gospel, 1891) and the Fuh-Kien Province of China (Church Missionary Society, 1887) consist of university men. Moreover, the older and larger societies have much increased the proportion of graduates on their staffs.

The cause of missions in the universities has been fostered greatly by the Student Volunteer Missionary Movement, initiated in America in 1886, and organized in England in 1892. The Union has over 3000 members (of whom 1400 have gone to the field), and has adopted as its watchword, "The Evangelization of the World in this Generation"; and this motto has been approved by several bishops and other Christian leaders. Another influence upon university men and others who have taken holy orders is that of the Younger Clergy Union of the Church Missionary Society (1885) and the Junior Clergy Association of the Society for the Propagation of the Gospel (1891). At the same time there has been a great accession of men to the missionary ranks from among other classes of society. The Anglican societies and the regular and older Nonconformist societies (Methodist, Baptist, Presbyterian and the London Missionary Society, which is virtually Congregationalist) have shared in these humbler recruits; but a large proportion of them have joined several younger "non-denominational" or "inter-denominational" missions. Of these the China Inland Mission is the largest and most influential; and while it has sent forth many of this class, it has also enrolled not a few men and women of considerable wealth, education and social status. The South Africa General Mission, the North Africa Mission, and the Congo Balolo Mission come next in importance; but there are several smaller bodies working in different countries. The Salvation Army also has missions in India, Ceylon and Japan; but these cannot be called "non-denominational," because the Army has gradually become a very strict denomination itself. There is one Anglican society working, like some of those just mentioned, in one particular field, viz. the South American Missionary Society, founded in 1844. Many foreign dioceses also have associations in England for their help and support. Medical men have come forward in increasing numbers for missionary service, and medical missions are now regarded as a very important branch of the work of evangelization. They are especially valuable in Mahommedan countries, where open preaching is difficult and sometimes impossible, and also in works of mercy among barbarous tribes; while in China, which comes under neither of these two categories, they have been largely developed. There are 980 doctors (most of them fully qualified) labouring in British and American missions; and in 1910 it was calculated that the in-patients in mission hospitals exceeded 160,000, while the visits of out-patients in a year were about 5,000,000. In several of the great London hospitals there are missionary associations, the members of which are medical students; but a chief source of supply in the past has been the Edinburgh Medical Mission, founded in 1841, which, while working among the poor in that city, has trained many young doctors for missionary service.

The most remarkable development of missionary enterprise has been the employment of women. From an early date many of the wives of missionaries have done good service; but the going forth of single women in any appreciable number has only been encouraged by the societies in the last quarter of the 19th century. The Society for Promoting Female Education in the East (now absorbed by others, chiefly by the Church Missionary Society) was founded in 1834; the Scottish Ladies' Association for the Advancement of Female Education in India (which subsequently became two associations, for more general work, in connexion with the Established and Free Churches of Scotland respectively) in 1837; the Indian Female Normal School Society (now the Zenana Bible and Medical Mission) in 1861 (taking over an association dating from 1852); the Wesleyan Ladies' Auxiliary in 1859; the Women's Association of the Society for the Propagation of the Gospel, and the Baptist Zenana Mission, in 1867; The London Society's Female Branch, in 1875; the Church of England Zenana Society (an offshoot from the Indian Female Society) in 1880. But the earlier of these organizations only contemplated employing women for educational work on a very small scale. Out of it grew the visitation of Indian zenanas. The employment of women in general evangelistic work, such as village itineration, house-to-house visiting in towns, classes for female inquirers, training of native female workers, &c., although recent, has rapidly extended. The Church Missionary Society, besides relying on the above-named Zenana Bible and Medical Mission and Church of England Zenana Missionary Society for women's work at several of its stations in India and China, sent out 500 single women in the fifteen years ending 1900; and the non-denominational missions above referred to have (including wives) more women than men engaged in their work—especially the China Inland Mission, which has sent out several hundreds to China. Women's work and medical work are combined in the persons of nearly 300 fully-qualified lady doctors in various missions. Although nearly half the male missionaries (Protestant) are unmarried, these are exceeded in number by the unmarried women; and consequently, the husbands and wives being equal, the aggregate of women in the Missions is greater than the aggregate of men.

The home organization of missions is a subject that has been much considered. The bulk of the work has been done by voluntary societies, membership in which depends upon a pecuniary subscription, and the administration of which is entrusted to elected committees. These committees comprise not only real experts, such as retired veteran missionaries, and retired civil and military officers who have been active friends of missions while on foreign service, but also leading clergymen and laymen who, though not personally acquainted with the mission fields, become almost equal experts by continuous attendance and careful study. In the case of the two leading Church of England societies, the bishops (being members) are *ex officio* on all executive committees; but their labours in other directions prevent their ordinarily attending. The numerous non-denominational missions previously referred to are differently worked. There is no membership by subscription, nor any elected committee. The "mission" consists of the missionaries themselves, and they are governed by a "director," with possibly small advisory councils in the field and at home, the latter undertaking the duty of engaging missionaries and raising funds.

On the other hand, there is a growing sense that missions should be the work of the Church in its corporate capacity, and not of voluntary associations. This is the system of the Presbyterian Churches, the missions of which are entirely controlled by the General Assemblies in Edinburgh, Belfast and London respectively. The Wesleyan Society also is under the authority of the Conference. In the Church of England the question was broached in Convocation, shortly after the revival of that body, in 1859; and during the next few years many suggestions were put forth for the establishment of a Board of Missions which should absorb the societies, or at least direct their work. It soon appeared, however, that neither the Society for the Propagation of the Gospel nor the Church Missionary Society was willing to be absorbed; and it was urged by some that in a great comprehensive national Church, comprising persons of widely different views, more zeal was likely to be thrown into voluntary than into official enterprises. Eventually, in 1887, the Canterbury Convocation and Archbishop Benson formed a Board of Missions; and York followed shortly afterwards. These boards, however, were not to supersede the societies, but to supplement their work, by collecting information, fostering interest, registering results and acting as referees when required. They have already done some useful work, and will probably do more. Their most active members are men who are also leaders in their respective societies, and have thus gained experience in missionary administration. But the Church of England has not yet put missions in the prominent place they occupy in the Nonconformist denominations.

The closing years of the 19th century were remarkable for the centenary commemorations of the older missionary societies. The Baptist Society celebrated its centenary in 1892; the London Missionary Society (Congregational) did the same in 1895; the Society for Promoting Christian Knowledge kept its bicentenary in 1898; the Church Missionary Society its centenary in 1899; the Society for the Propagation of the Gospel its bicentenary in 1900–1901; and the British and Foreign Bible Society its centenary in 1904. Considerable special funds have been raised in connexion with these commemorations. A good deal of interest has also been awakened and maintained by missionary exhibitions, and by a more intelligent type of missionary literature.

2. Colonial.

Colonial missions next claim attention. By "colonial" is meant, not missions to the British colonial population, but missions from the colonial population to the heathen. The former have been very largely the work of the Society for the Propagation of the Gospel, and, in a smaller degree, of the Colonial Church Society (Church of England) and the Colonial Missionary Society (Congregational). Those missions, however, are more properly an outlying branch of home missions, being to the professing Christian settlers or their descendants. But these Christian settlers have their own missions to the heathen—both to the heathen at their doors and to the great heathen lands beyond.

In Canada and Australia, the Anglican, Presbyterian, Methodist, Baptist and other communities have regular organizations for foreign missions. The non-episcopal missions thus formed and supported are worked quite independently of the home societies of the denominations respectively. The Australian Presbyterians have important agencies in the South Seas and in Korea, the Australian Baptists in Bengal, the Canadians of various denominations in the Far North-West of the Dominion, and in India and China. The Anglican Church in Canada has its Domestic and Foreign Missionary Society, working in the North-West and in Japan; and in Australia it has a Board of Missions, working amongst the Australian aborigines and in New Guinea. The Melanesian Mission, associated with the names of Selwyn and Patteson, is officially connected with the Church of New Zealand, but is also largely supported in Australia. In New South Wales, Victoria, New Zealand and Canada there are also Church missionary associations which supply missionaries, and support them, for the mission fields of the Church Missionary Society.

3. Continental.

The *German* societies are numerous and important, and have increased in number and in vigorous work. The *Moravian Church*, whose missions are the oldest (1732), is itself a missionary organization in a sense in which no other Christian community rivals it. Its total membership is under 100,000, and it has some 350 missionaries, labouring in the most unpromising fields—Greenland, Labrador, Alaska, Central America, Tibet, and among the Hottentots. The *Basel Society*, with its famous seminary at Basel, which formerly supplied many able German missionaries to the Church Missionary Society, has extensive work in India, West Africa and South China. The *Berlin Society* and the *Rhenish Society* labour in South Africa and China, the *Hermannsburg Mission* (Hanover) in South Africa and India; *Gossner's Mission* (Berlin) and the *Leipzig Lutherans* in India. At least two of these societies, and other new associations formed for the purpose, and the Moravians, have taken up work in German East Africa. The principal organizations in Holland are the Netherlands Missionary Society and the Utrecht Missionary Society, working mainly in the Dutch colonies. A *Danish* society has a mission in South India. The old *Swedish* and *Norwegian* missionary societies work in South Africa, Madagascar and India; but large numbers of Scandinavians have been stirred up in missionary zeal, and have gone out to China in connexion with the China Inland Mission; several were massacred in the Boxer outbreaks. The *French* Protestants support the *Société des Missions Évangeliques*, founded in 1822. Its chief mission has been in Basutoland, since extended to the Zambesi; but it has also followed French colonial extension, establishing missions in Senegambia, the French Congo, Madagascar and Tahiti.

4. American.

The newer American organizations are, as in England, non-denominational and "free-lance," especially the Christian and Missionary Alliance (1897), developed from the International Missionary Alliance (1887), which has sent many missionaries to India and China. The older societies attribute to these new agencies more zeal than discretion, while the newer credit the older with a discretion that cripples zeal. The Student Volunteer Movement, already referred to, has had large influence in the United States, where it arose; and its leaders have proved themselves men of rare intellectual and practical capacity. In a journey round the world in 1895–1897, J. R. Mott succeeded in forming students' associations in universities and colleges in several European countries, as well as in Turkey in Asia, Syria, India, Ceylon, China, Japan and Australia; and all these associations, over 150 in number, are now linked together in a great International Student Federation. The older American societies, especially the American Board (Congregational), the Presbyterian Boards, the Methodist Episcopal Church Society, the Baptist Missionary Union, and the Missionary Society of the Protestant Episcopal Church, have much extended their work. The "Ecumenical Missionary Conference," held at New York in April 1900, was an astonishing revelation to the American public of the greatness of missions generally and of the missions of their own churches in particular. The Laymen's Missionary movement is a significant outcome of the interest then awakened.

Missions to the Jews are worked by distinct organizations. There are several societies in England, Scotland, Germany and America. No special development has to be reported, except the great extension of John Wilkinson's *Mildmay Mission to* *the Jews*, and its energy in the free distribution of Hebrew New Testaments.

5. Missions to the Jews.

Converted Jews are commonly supposed to be very few, and in numbers they do not compare with converted heathen; but they are more numerous than is usually imagined, especially if the second and third generations of Christians of Hebrew race are included. A number of them find in Unitarianism a form of Christianity that appeals to them. It is estimated that 250 Anglican clergymen are converted Jews or the sons of converted Jews. The London Society for Promoting Christianity among the Jews includes among its missionaries about 80 who are converts. Professor Delitzsch estimated that 100,000 Jews had embraced Christianity in the first three quarters of the 19th century; and Dr Dalman of Leipzig says that "if all those who have entered the Church and their descendants had remained together, instead of losing themselves among the other peoples, there would now be a believing Israel to be counted by millions, and no one would have ventured to speak of the uselessness of preaching the Gospel to the Jews."

Interesting as is the story of Protestant mission work in Austria, Spain, Italy and Russia, it does not fall within the scope of this article. Nor do the proselytizing enterprises of Seventh Day Adventists, Christian Scientists, Mormons and other American bodies rightly find a place here.

Roman Catholic Missions.—At the beginning of the 19th century the Roman Communion seems to have shared to some extent in the torpor and stagnation as regards missions that characterized the Protestant churches. There was little of the zeal which had carried the Franciscans all over Asia in the 13th century, and the Jesuits to South America, India and Japan in the 16th. But the 19th century witnessed a great change, and Roman Catholic missions have been extended *pari passu* with Protestant. The revival was not a little due to the foundation in 1822, by a few earnest but (as they called themselves) "humble and obscure" Catholics at Lyons, of a new voluntary society, called the Institution for the Propagation of the Faith. It collected in its first year about £2000 from the shopkeepers and artisans of Lyons. Thirty years later its income was £200,000 a year; and now it is £300,000. It has sent out no missionaries of its own. It merely makes grants to the various missionary parties sent forth, and it has done much in this direction. Roman missions are carried on both by missionary societies and by religious orders, all under the supreme direction of the pope, and also more or less under the general supervision of the Sacra Congregatio de Propaganda Fide at Rome since its foundation by Gregory XV. in 1622. This important congregation has been described as corresponding pretty much in the Catholic Church to the colonial office in the British empire, and its head, the "Prefect of Propaganda," to the secretary of state for the colonies. It holds supreme control over all the foreign missions in heathen countries, and also over large and important parts of the church in Christian countries whose governments are not Catholic—including the British empire, the United States, Holland, the Norse kingdoms, Greece, and some parts of Germany and Switzerland. A special section (erected by Pius IX.) has charge of the affairs of all the Oriental rites in union with the Roman see. Confining our attention at present to the missions strictly understood under "foreign," *i.e.* to heathen or non-Christian countries, we shall find the whole of these parts of the globe carefully mapped and parcelled out by propaganda to a variety of missionary agencies or religious orders. The government of the various mission fields is generally carried on by "Vicars-Apostolic" (*i.e.* titular bishops acting as vicars or delegates of the Apostolic see) or "Prefects-Apostolic" (*i.e.* priests with similar powers, but without episcopal rank). In some few cases (notably India and Japan) a regular territorial hierarchy has been established, just as in the United Kingdom and the Netherlands. Of the religious societies engaged in the evangelization of these many fields of labour, some have been established exclusively for foreign missionary work among the heathen—notably the famous Société des Missions Étrangères of Paris, the oldest and greatest of all (dating from 1658, and consisting of 34 bishops, 1200 European missionaries and 700 native priests); the German "Society of the Divine Word," whose headquarters are at Steyl in Holland; the Belgian Society of Scheat; the celebrated French Society of the "White Fathers," founded by the late Cardinal Lavigerie for African missions; the English Society of St Joseph, founded at Mill Hill by Cardinal Vaughan; and some others. The other missions are entrusted to the care of various religious orders and congregations, which take up foreign missionary work in addition to their labours in Christian countries. Such are the Franciscans, Dominicans, Jesuits, Lazarists, Augustinians, Marists, &c. Besides the above orders of priests, an immense number of religious societies of women are engaged in works of education and charity throughout the whole of the foreign mission field. These have been reckoned at about 42,000 European and 10,000 native sisters. Again, there are some 20 congregations of "Brothers" (not priests) engaged in teaching, and numbering some 4500 members.

By far the greater part of the Roman missionary work is done by France. The majority of the missionaries are French (over 7000); the bulk of the money—so far as it is voluntary contribution (but the propaganda at Rome has large endowments)—is raised in France. The French government, anti-clerical as it is at home, is the watchful and strenuous protector of the missions abroad; and it is evident that not a little political influence in foreign countries is gained thereby. *L'Année de l'Église*, in reporting on the missions in all parts of the world, dwells continually on this with satisfaction. Protestant missionaries are opposed, not merely because they are heretical, but because they are English or (if American) English-speaking; and the Greek Church missionaries in Persia and Japan, not only because they are schismatic, but because they are Russian—the Franco-Russian alliance notwithstanding. This is a feature in French Catholic missions which cannot be overlooked in the briefest account of them.

The following list shows the principal foreign Roman Catholic missionary societies and their fields of work:—

I. *Société des Missions Étrangères* (Paris, 1658).—*Missions*: Manchuria, Korea, Tibet, Japan, China (Sze-Chuen, Kui-Chow, Kwang-tong, Yunnan), Indo-China (W., S. and Upper Tongking, E., W. and N. Cochin-China; Cambodia, Siam), Malay Peninsula, Burma (S. and N.), S. India (dioceses of Pondicherry, Kombakonam, Mysore, Coimbatore).

II. *Society of "White Fathers"* (founded by Cardinal Lavigerie, 1868).—*Missions*: Algeria, Sahara, Nyasa, Victoria Nyanza, Tanganyika, Unyanyembe, Upper Congo.

III. *Lyons Seminary for Foreign Missions* (1856).—*Missions*: Nile Delta, Benin, Ivory Coast, Gold Coast, Dahomey, Upper Niger.

IV. *Congregation of the Holy Ghost* (1703 and 1848).—*Missions*: Senegambia, Gambia, Sierra Leone, Lower Niger, Gaboon, French Congo, Lower Congo, Mayotte, Nossibé and Comoro Islands.

V. *Milan Seminary for Foreign Missions* (1850).—*Missions*: China (Hong Kong, N. and S. Ho-nan), East Burma, India (dioceses of Kishnagar and Haidarabad).

VI. *Steyl Society of Foreign Missions* (German, 1875).—*Missions*: S. Shan-tung, China; Togo, W. Africa.

VII. *Scheat Society of Foreign Missions* (Belgian, 1863).—*Missions*: Mongolia, Kang-Su (China), Belgian Congo.

VIII. *Picputian Society*[1] (Paris, 1817).—*Missions*: Hawaii, Tahiti, Marquesas Islands.

IX. *Mill Hill Society* (English, 1866).—*Missions*: N. Borneo and Labuan; N. Punjab, Kashmir and Ladak; Telugu missions of Madras; Maori missions of N. New Zealand; N. Uganda.

X. *Congregation of the Sacred Heart* (Issoudun, France, 1855).—*Missions*: New Guinea, New Pomerania, Gilbert Islands.

XI. *Society of the Divine Saviour* (Rome, 1881).—*Mission*: Assam.

XII. *Verona Society for African Missions.*—*Mission*: The Sudan, Upper Egypt.

The following societies are engaged in home as well as foreign missions:—

XIII. *Marists* (French, 1816).—*Missions*: Fiji, Navigator's Island, New Caledonia, Central Oceania, Solomon Islands, parts of New Zealand (dioceses of Wellington and Christchurch).

---

[1] Father Damien belonged to this society, which takes its popular name from the Rue de Picpus, Paris.

XIV. *Lazarists* (founded by St Vincent de Paul, 17th century).—*Missions*: Abyssinia, Persia, China (Peking or N. Chih-li, S.-W. Chih-li, Kiang-si, Che-Kiang), S. Madagascar.
XV. *Oblates of Mary Immaculate* (1840).—*Missions*: Ceylon (nearly all), S. Africa (Basutoland, Natal, Transvaal, Orange River Colony), the "Great North-West" of Canada (Athabasca-Mackenzie, Saskatchewan, St Boniface, New Westminster).
XVI. *Salesians* (founded by Don Bosco).—*Missions*: Patagonia and Tierra del Fuego, Falkland Islands, Indians of S. America (Ecuador, Brazil, Argentine); some missions in Palestine.
XVII. *Pallottines.—Missions*: Cameroon, W. Africa; Australia (Beagle Bay, native settlement).
XVIII. *Jesuits.—Missions*: India (dioceses of Bombay, Poona, Calcutta, Madura, Mangalore, Trichinopoly), Ceylon (dioceses of Galle and Trincomalee), China (Kiang-nan, S.-E. Chih-li), Madagascar, Koango (W. Africa), Zambezia, Jamaica, British Guiana, British Honduras, Alaska.
XIX. *Dominicans.—Missions*: Asiatic Turkey (Mosul), Tongking (N., E. and Central), China (Amoy, Fokien), Curaçao, Trinidad.
XX. *Franciscans.—Missions*: Egypt, Tripoli, Morocco, China (N. and S. Shan-si, N. and E. Shan-tung, N. Shen-si, E., N.-W. and S.-W. Hu-pe). *Capuchins*: Aden and Arabia, India (dioceses of Agra, Allahabad, Lahore), Seychelles, Eritrea (Red Sea), Gallas, Cephalonia, Trebizond, Mardin, Crete, Caroline Islands, Araucania, Brazil, Bulgaria. *Conventuals*: Jassy (Rumania).
XXI. *Benedictines.—Missions*: Ceylon (diocese of Kandy), New Zealand (diocese of Auckland), N. American Indians (Indian Territory and Oklahoma), Australian natives (New Nursia).
XXII. *Trappists.—Missions*: Settlements in Natal (Marianhill), West Africa (Congo), China, Japan.
XXIII. *Augustinians.—Missions*: Philippines, China (N. Hu-nan), Balkan Peninsula, Asia Minor ("Assumptionists").
XXIV. *Carmelites.—Missions*: Bagdad, India (dioceses of Verapoly and Quilon).
XXV. *Redemptorists.—Missions*: Dutch Guiana.
XXVI. *Passionists.—Missions*: Bulgaria (diocese of Nicopolis).

These missions are largely supported by the Society of the Propagation of the Faith (est. in Lyons, 1822), Society of the Holy Childhood (est. 1843 as auxiliary to the former; "children for children") and Society of the Schools of the East (est. 1855).

On figures given in H. A. Krose's *Katholische Missionsstatistik* (1908), the following totals of Roman Catholic Missions amongst non-Christians have been compiled: European priests, 7933; native priests, 5837; lay brothers, 5270; sisters, 21,320; catechists, 24,524; native membership, 7,441,215; catechumens, 1,517,909. The annual baptisms of adult heathen are 190,000; those of heathen children at the point of death, 450,000. Over 840,000 children are in lower schools, 66,000 in middle schools, and 90,000 in orphanages. The total number of schools is 24,000, of churches and chapels 28,000, and of mission stations 43,000.

Note.—Where figures for 1910 are quoted in this article they are really those of two or three years earlier, collected for the World Conference of 1910.

Orthodox Eastern Church.[1]—When the tsar Ivan the Terrible (1533–1584) began the great advance of Russia into Northern Asia, a large number of missionaries accompanied the troops, and during the 17th century many thousands of Tatars were baptized, though from lack of fostering influences they lapsed into heathenism. Very little was done until 1824, when John Veniaminov (d. 1879), a priest of Irkutsk, afterwards Archbishop Innocent, began a career of evangelistic activity which has few parallels. He founded missions in Alaska and the Aleutian Islands, Kamtchatka and throughout Eastern Siberia, and established the Orthodox Missionary Society at Moscow. In Altai (Central Siberia) the Archimandrite Macarius, and among the Tatars in south-east Russia with headquarters at Kazan the great linguist Ilminski, did similar work. In addition to the nine distinct missions (300 workers) in Siberia and the six (with 50 workers) in European Russia, the Orthodox Church (Russian) has three foreign missions: (1) in China, founded at Pekin 1714, in the face of Jesuit opposition; (2) in Japan, established about 1863 by Bishop Nicolai, a chaplain at Nagasaki; (3) in Alaska and the Aleutian Islands, the bishop residing at San Francisco and having jurisdiction also over members of the church settled in the United States of America. Altogether the Russian Church spends over £30,000 annually on these missions, and works with the British and Foreign Bible Society in translating and distributing the Scriptures. In Japan the mission has become a practically independent branch of the Church.

History of Mission Fields

The continuity of missionary enthusiasm maintained through the primitive, the medieval, and the modern periods of the Church's history, operating at every critical epoch, and surviving after periods of stagnation and depression, is a very significant fact. It is true that other religions have been called missionary religions, and that one of them long held first place in the religious census of mankind. The missionary activity of Buddhism is a thing of the past, and no characteristic rite distinguishing it has found its way into a second continent. Mahommedanism indeed is active, and is the chief opponent of Christianity to-day, but the character of its teaching is too exact a reflection of the race, time, place and climate in which it arose to admit of its becoming universal. It is difficult to trace the slightest probability of its harmonizing with the intellectual, social and moral progress of the modern world. With all its deficiencies, the Christian church has gained the "nations of the future," and whereas in the 3rd century the proportion of Christians to the whole human race was only that of one in a hundred and fifty, this has now been exchanged for one in three, and it is indisputable that the progress of the human race at this moment is identified with the spread of the influence of the nations of Christendom.

Side by side with this continuity of missionary zeal, a noticeable feature is the immense influence of individual energy and the subduing force of personal character. Around individuals penetrated with Christian zeal and self-denial has centred not merely the life, but the very existence of primitive, medieval and modern missions. What Ulfilas was to the Gothic tribes, what Columba and his disciples were to the early Celtic missions, what Augustine or Aidan was to the British Isles, what Boniface was to the churches of Germany and Anskar to those of Denmark and Sweden, that, on the discovery of a new world of missionary enterprise, was Xavier to India, Hans Egede to Greenland, Eliot to the Red Indians, Martyn to the church of Cawnpore, Marsden to the Maoris, Carey, Heber, Wilson, Duff and Edwin Lewis to India, Morrison, Gilmour, Legge, Hill, Griffith John to China, Gray, Livingstone, Mackenzie, Moffat, Hannington, Mackay to Africa, Broughton to Australia, Patteson to Melanesia, Crowther to the Niger Territory, Chalmers to New Guinea, Brown to Fiji.[2] At the most critical epochs such men have ever been raised up, and the reflex influence of their lives and self-denial has told upon the Church at home, while apart from their influence the entire history of important portions of the world's surface would have been altered.

If from the agents themselves we turn to the work that has been accomplished, it will not be disputed that the success of missions has been marked amongst rude and aboriginal tribes. What was true in the early missions has been found true in these latter times. The rude and barbarous northern peoples seemed to fall like "full ripe fruit before the first breath of the gospel." The Goths and the Vandals who poured down upon the Roman Empire were evangelized so silently and rapidly that only a fact here and there relating to their conversion has been preserved. This is exactly analogous to modern experience in the South Seas, Asia and Africa, to a survey of which we now turn.

The South Seas.—Missionary work in the Pacific began with Magellan (1521), when in a fortnight he converted all the inhabitants of Cebú and the adjacent Philippine Islands! The Jesuits, Recollets and Augustinians also worked in Mariana, Pelews and Caroline Islands, though the two latter were soon abandoned. The beginning of modern effort was made by the London Missionary Society in 1797.

[1] See E. Smirnoff, *Russian Orthodox Missions*; an article in *The East and the West* (April, 1904); and the *Statistical Atlas* (1910), p. 99.

[2] E. Stock's *Short Handbook of Missions* has a chapter on "Some Notable Missionaries" and another on "Some Prominent Native Christians."

Australia and New Zealand.—The earliest attempt to evangelize the aborigines of Australia by a separate mission was that of the Church Missionary Society in 1825. This work centred at Wellington Valley and Moreton Bay, but was given up in 1842. A new beginning was made in 1850 by the Anglican Board of Missions for Australia and Tasmania, and now each diocese is responsible for its own area. At Bellenden Ker, near Cairns, in North Queensland (diocese of Carpentaria), many natives have settled upon a reserve granted by government to the Anglican Church, and at another reserve, Fraser Island, the diocese of Brisbane has also undertaken successful work. Nomadic aborigines have hardly been touched. Apart from Queensland most of the black population is in West Australia; here the Roman Catholic Church is the main evangelizing agency. In the north and central districts the German missions have been active. Both in Australia (especially in Sydney and Melbourne) and at Thursday Island there is work among the Chinese.

In Tasmania the aborigines are extinct, the last pure-blooded native dying in 1876. The half-castes settled in the Bass Straits are ministered to by the bishop of Tasmania. The Maoris of New Zealand first came under Christian influence through the efforts of Samuel Marsden, a colonial chaplain in New South Wales about 1808. In 1822 Wesleyan missionaries reached the island. The first baptism was in 1825 but during the next five years there was a great mass movement. In 1840 the country became a British colony, and soon afterwards George Selwyn was consecrated bishop. He was so impressed with the work of native evangelists that he founded a college in Auckland where such teachers could be trained. In this he was helped by J. C. Patteson, and out of it grew the Melanesian Mission. The Maori rebellion, fomented by French Catholics, was an outbreak against everything foreign, and the strange religion Hau-hauism, a blend of Old Testament history, Roman Catholic dogmas, pagan rites and ventriloquism, found many adherents. Yet the normal missionary organization suffered very little. Later came Mormon missionaries, and these have to some extent further depleted the Christian ranks.

New Guinea.—In this large island some Gossner missionaries (1854) were the pioneers. They could not do much, but their successors, the Utrecht Missionary Union, who began work when the Dutch took possession of the north-west of the island, are making themselves felt through their six stations. In German New Guinea the Neuendethelsau (1886) and Rhenish (1887) Societies have fourteen stations. In British New Guinea, the south-east portion of the island, the London Mission (1871), the Australian Wesleyans (1892) and the Anglican Church of Australia (1892), have arranged a friendly division of the field and met with gratifying success. Work was begun in 1871–1872 when under the oversight of S. Macfarlane and A. W. Murray a number of native teachers from the Loyalty Islands Rarotonga and Mare settled on the island. The first converts were baptized in 1882 and the establishment of a British Protectorate (1884–1888) gave the work a new impetus. The name of W. G. Lawes and James Chalmers (who with O. Tompkins was killed by cannibals, 1901) of the London Missionary Society, and that of Maclaren, the pioneer of the Church Missionary Society's work, are immortally associated with Papua. The history of mission work here is one of exploration and peril amongst savage peoples, multitudinous languages and an adverse climate, but it has been marked by wise methods as well as enthusiastic devotion, industrial work being one of the basal principles. Besides the Protestant agencies already named, the Roman Catholic Order of the Sacred Heart has been working in the island since 1886; its centre is at Yule Island, and it works up the St Joseph's river.

Other Islands.—The London Mission ship "Duff" in 1797 landed eighteen missionaries (mainly artisans) at Tahiti, ten more in the Tonga or Friendly Islands, and one on the Marquesas. Those in Tahiti had a varying experience, and their numbers were much reduced, but in July 1812 King Pomare II. gave up his idols and sought baptism. By 1815 idolatry was abolished in the larger islands of the group and there ensued the task of building up a Christian community. Foremost in this work were William Ellis (*q.v.*) and John Williams (*q.v.*), who formed a native agency to carry the gospel to their fellow islanders, and so inaugurated what has since been a characteristic feature of South Sea Missions. In 1818 two Tahiti teachers settled in the Tonga islands, which the "Duff" pioneers had abandoned after half of them had been killed for a cannibal feast. When the Wesleyans came in 1821 the way had been prepared, and soon after, led by their king, George, the people turned to the new faith. About the same time Rurutu in the Austral Islands and Aitutaki in the Cook Islands were evangelized, also by natives, and Christianity spread from island to island. John Williams himself removed in 1827 to Rarotonga and from there influenced Samoa, the Society Islands and Fiji. To Fiji in 1834 came James Calvert and other Wesleyan missionaries beginning a work which under them and their successors had extraordinary success. Williams met his death at Erromanga in 1839, but he had established a training school on Rarotonga, and bought a ship, the "Camden," which was of the greatest service for the work. In 1841 work was begun in New Caledonia, in 1842 in the Loyalty Isles and in the New Hebrides, associated from 1857 with the memorable name of John G. Paton. In 1846 a teacher was placed on Niué, Savage Island, and in ten years it was evangelized. Meanwhile the original work in Tahiti had been taken over by missionaries of the Paris Society, though the last London Missionary Society agent did not leave that group till 1890. In 1861 Patteson was consecrated bishop of Melanesia, and the Auckland training school was removed to Norfolk Island. By arrangement with the Presbyterians the area of the mission includes the Northern New Hebrides, Banks, Torres, Santa Cruz and Solomon Islands. Patteson was murdered in 1871, a victim of the mistrust engendered in the natives by kidnapping traders. In 1877 John Selwyn was consecrated bishop. Wesleyan native evangelists from Fiji and Tonga carried Christianity in 1875 to the Bismarck Archipelago.

The solitary worker (W. P. Crook) on the Marquesas did not remain long, and after he went nothing was done till 1833–1834, when first some American and then some English missionaries arrived, but met with scant success and gave it up in 1841. Since 1854 teachers from the Hawaiian Islands have worked in the Marquesas, but results here have been less fruitful than anywhere else in the South Seas. In Hawaii itself much was accomplished by American missionaries, the first of whom were H. Bingham and A. Thurston (1820), and the most successful, Titus Coan, under whose leadership over 20,000 people were received into the churches between 1836 and 1839. Under the reign of Kalakaua (1874–1891) there was a strong reaction towards heathenism, but since the annexation of the islands by the United States of America the various churches of that land have taken up the task of evangelization and consolidation.

In the Micronesian Islands, while animism and tabu were strong, there was not the cannibalism of the southern islands. Work was begun in the Caroline Isles in 1852 and in time spread to the Gilbert and Marshall groups. In the Carolines and Marshalls it has now largely passed to German missionaries, the Americans having enough to do in the Philippines, where there are already over 27,000 Protestants.

The outstanding features of missionary work in the South Seas are (1) its remarkable success: cannibalism, human sacrifice and infanticide have been suppressed, civilization and trade have marvellously advanced; (2) the evangelical devotion of the natives themselves; (3) the need of continued European supervision, the natives being still in many ways little better than grown-up children.

Africa.[1]—In Africa, as in the South Seas, mission work has gone hand in hand with geographical discovery. It is in every sense a modern field, or rather a collection of fields, varying in physical, racial, social and linguistic character. The unaccustomed conditions of life and the fatal influence of the climate have claimed as many victims here as did savagery in the Pacific

Islands. The partition of the continent among the various European nations has been on the whole favourable to mission work. The nature of the task and of the results may be best approached by considering the different divisions—North, South, East, West and Central Africa.

North Africa, along the Mediterranean from Morocco to Egypt, is distinctly Mahommedan. To these regions came St Louis and Raimon Lull, and one may in passing remember the strength of Christianity in Proconsular Africa in the days of Tertullian and Cyprian, and in Egypt under Clement of Alexandria, Origen and Athanasius. To-day Islam is supreme, though the North Africa Mission, working largely on medical lines, has penetrated into many cities. In Egypt the United Presbyterians of America have met with considerable success among the Copts, and their fine educational work has proved a valuable asset both to themselves and the country. The Church Missionary Society is doing steady work in Cairo and in Upper Egypt. In the Eastern Sudan a promising beginning has been made, but the regions south of Kordofan have hardly been touched. In Nigeria the Hausa tribes are coming to be better known, and to respond to the Christian teaching. In the Sahara and at Suakin there are Roman Catholic missions. There is a Roman mission to the Gallas in Abyssinia. That country has its own crude form of Christianity, and is much the same today as when Peter Heiling in the 17th century endeavoured to propagate a purer faith. A mission undertaken by the Church Missionary Society in 1830 was closed by French Jesuit intrigue in 1838.

South Africa.—The Moravians, represented by George Schmidt, who arrived at Cape Town in July 1737, were the first to undertake mission work in South Africa. Schmidt won the confidence of the Hottentots, but the Dutch authorities stopped his work. In 1798 John T. Vanderkemp, an agent of the London Missionary Society, founded a mission to the Kaffirs east of Cape Town, and Robert Moffat (1818) went to the Bechuanas. David Livingstone was as determined to open the interior as the Boers were to keep it shut, and he succeeded, pushing north, discovering Lake Ngami, and consecrating a remarkable life to the evangelization of Central Africa. The London Mission has also largely evangelized the Matabele. In 1814 the Wesleyans began work among the Namaquas and Hottentots, and afterwards went into Kaffraria, Bechuanaland and Natal. They were followed by the Glasgow Missionary Society (1821), the Paris Evangelical Society (1829), the Moravian, Rhenish and Berlin Societies, and the American Board. The Society for the Propagation of the Gospel came in 1819, mainly for colonists, the Church Missionary Society in 1837. The province of South Africa has ten dioceses, the bishop of Cape Town being metropolitan. The Glasgow Society's work was ultimately taken over by the Free Church of Scotland, whose great achievement is the Lovedale Institute, combining industrial and mission work. The Germans and Scandinavians have also been ardent workers in South Africa, and the Dutch Reformed Church has not entirely neglected the natives. One Dutch society gives its attention to the northern part of the Transvaal. The chief difficulties in the way of evangelization have been (1) the hostility of natives races aroused by European annexations, (2) the introduction of European vices, (3) the movement known as Ethiopianism. The British Wesleyans refused to confer full rights on negro pastors, who then appealed to the African Methodist Episcopal Church, a product of American evangelization. One of them, J. M. Dwane, was made Vicar-Bishop, and a large and powerful independent negro church organized. Dwane afterwards approached the Anglicans, and in 1900 that church formed the "Ethiopian Order," ordaining Dwane a deacon and making him Provincial of the Order. Each bishop now deals with the Ethiopians in his own diocese. The South African governments foresaw dangerous developments in the Ethiopian movement, and steps were taken to restrain its growth. Ethiopianism, if ecclesiastical in its origin, gained strength from racial base. The task of averting the racial bitterness so dominant in the United States of America is a most formidable one. There are in South Africa several vicariates and prefectures of the Roman Church, the principal missions being French, those of the Congregation of the Holy Ghost and the Oblates of Mary.

West Africa was first visited by the Society for the Propagation of the Gospel in 1752. Its agent, T. Thompson, trained Philip Quaque, said to be "the first convert who ever received ordination since the Reformation in the Reformed Church." The Church Missionary Society came in 1804 and has worked heroically and successfully, though the largest mission now is that of the Wesleyans, who came in 1811, settling first at Sierra Leone. The American Baptists in Liberia (1821) and the Basel Mission in the Gold Coast (1827), the Congregationalists of the United States of America and Canada in Angola, and the English and American Baptists on the Congo (since 1875) have also extensive and prospering agencies. West Africa has taken heavy toll not only in money but in life, but the lesson has now been learned, and a system of frequent furloughs combined with a better understanding of the climatic requirements have appreciably lessened the peril. This region is linked with the name of the Anglican negro Bishop, Samuel Crowther, and with one phase of the ceaseless strength of Islam, which has so far failed to reach the west coast, finding itself confronted by the Christian influences which are at work among the great Hausa tribes and other peoples within the area of the Niger mission. The Portuguese in Angola and the agents of King Leopold in the Congo State have not been conspicuous friends of missionary enterprise, and the light-hearted childishness of the native character, so well portrayed in Miss Kingsley's writings, shows how difficult it is to build up a strong and stable Christian church. Bishop Taylor's effort at creating a self-supporting mission proved fruitless. The American Lutherans are attempting the same task on rather different lines, and with more promise. The Roman Catholic missions are chiefly French, and organized by the Congregation of the Holy Ghost and the Lyons African Mission.

Central Africa.—The upper Congo region opened up by Livingstone and Stanley has been a favourite sphere for what are known as "faith societies," *e.g.* the Plymouth Brethren, the Christian and Missionary Alliance, the Regions Beyond Missionary Union. The American Baptists continue the work started by the Livingstone Inland Mission in 1878, and the Southern Presbyterian Board (American) have done notable work. The Paris Society, represented especially by François Coillard, has been successful along the Zambezi, and Scottish, German, Moravian and Jesuit agencies are also well represented. Northward, Central and East African organizations, following the Cape to Cairo route, are in touch with North African agencies working up the Nile.

East Africa.—When the Abyssinia mission was closed in 1838 one of the missionaries, Krapf, went among the Gallas and then on to Mombasa, working in company with Rebmann. Since H. M. Stanley's appeal (1875) most satisfactory work, extensive and intensive, has been accomplished in Uganda, by the Church Missionary Society. The names of Mackay, Hannington and Pilkington, who lived and died here, are amongst the greatest in the roll of missionary heroes. The Roman Mission too has been very successful; for some years a French agency, the White Fathers of Algeria, carried it on, but they were afterwards joined by English helpers from St Joseph's Society at Mill Hill. The White Fathers also work in the Great Lakes region, and on the Zanzibar coast are the French Congregation of the Holy Ghost and German Benedictines. Zanzibar is also one of the centres of the Universities Mission, another being Likoma on Lake Nyasa. Near this lake the Scottish churches are also doing noble work. Besides Uganda the Church Missionary Society is responsible for Mombasa. The London Mission is meeting with success at the south end of Lake Tanganyika in North-east Rhodesia. The English United Methodists and some Swedish societies have begun work among the Gallas. German Missionary agencies have also come in with German colonization. In East Africa, as in the West, Christian missionaries fear most the aggressive Moslem propaganda.

Madagascar[1] is one of the most interesting mission fields. Work was begun by the London Mission in 1819, and the work of civilization and evangelization went steadily forward till 1835, when a period of repression and severe persecution set in, which lasted till 1861. When the work was recommenced it was found that the native Christians had multiplied and developed during the harsh treatment of the 25 years. In 1869 the idols were publicly destroyed and the island declared Christian by royal proclamation. The Society for the Propagation of the Gospel (1864), the Norwegian Missionary Society (1866), and the Friends' Foreign Missionary Association joined in the work, the prosperity of which received a severe check by the French annexation in 1896. The French authorities were hostile to the English missionaries, and even the handing over of part of the field to the Paris Evangelical Society did not do much to ease the situation. Laws were first enacted against private schools, then against elementary schools, and in 1906–1907 measures were passed which practically closed all mission schools. Family prayers were forbidden if any outside the immediate family were present, and religious services at the graveside were prohibited. Missionary work in the island has thus passed through a peculiarly trying experience, but happier conditions are now likely to prevail. In Mauritius and the Seychelles the Church Missionary Society and the Society for the Propagation of the Gospel are at work, especially among the coolies on the sugar plantations.

The outstanding problem of African missions at least north of the Equator (south there is the Ethiopian question) is not the degradation of the black races, nor the demoralizing influences of heathen Christians, nor even the slave dealer, though all these obstacles are present and powerful. The all-decisive conflict is that between Christianity and Islam, and the Christian agencies must show much more co-operation if they are to be successful. The lines of missionary work have been, generally speaking, simple gospel preaching followed by education and industrial work. So rare were the ordinary comforts, and even necessities of life, that the latter had to take a prominent place from the beginning: the missionary had to be farmer, carpenter, brickmaker, tailor, printer, house and church builder, not only for himself but for his converts. The work of Bible translation has been particularly long and difficult; for the innumerable peoples who did not speak some form of Arabic the languages had first to be reduced to writing, and many Christian terms had to be coined.

India.[2]—The earliest missionaries to India, with the possible exception of Pantaenus of Alexandria (*c.* A.D. 180), were the Nestorians from Persia. The record of their work is told elsewhere (see NESTORIUS and NESTORIANS). The Jesuits came in the 16th century, but were more successful quantitatively than qualitatively; in the 18th century the Danish coast mission on the coast of Tranquebar made the first Protestant advance, Bartholomäus, Ziegenbalg (1683–1719), Plutschau and Christian Friedrich Schwartz (1726–1798) being its great names. Up to this time the chief results were that (1) Christianity had gained a footing, (2) it had continued the monotheistic modification of Indian thought begun by Mahommedanism, and (3) the futility of sporadic and fanatical proselytism had been shown. A new era began with the arrival of William Carey and the founding of the Serampur Mission (15 m. north of Calcutta), though the hostility of the East India Company made the early years of the 19th century very unproductive. When Carey died in 1834 he and his colleagues Marshman and Ward had translated the Bible into seven languages, and the New Testament into 23 more, besides rendering services of the highest kind to literature, science and general progress. They founded agricultural societies and savings' banks, and helped to abolish suttee, infanticide and other cruelties. At Travancore in the south, Ringeltaube, an agent of the London Missionary Society, had begun a work, especially among the Shanars or toddy drawers, which by 1840 had 15,000 Christians; and the Church Missionary Society, led by Rhenius, had equal success in Tinnevelly. The Baptists, drawn by the fame of the temple of Jagannath at Puri on the east coast, established a mission in Orissa in 1821 which soon bore fruit; the Wesleyans were in Ceylon, Mysore and the Kaveri valley, the London Missionary Society at the great military centres Madras, Bangalore and Bellary, agents of the American Board at Ahmednagar and other parts of the Mahratta country around Bombay. The headquarters of Hinduism, the Ganges valley, was occupied by the Baptists, the Church Missionary Society and the London Missionary Society, these entering Benares in 1816, 1818 and 1820 respectively. Alexander Duff, a Scottish Presbyterian, had begun his great educational work in Calcutta, and Bible tract and book societies were springing up everywhere. Chaplains and bishops of the Anglican Church like James Hough in Tinnevelly, Henry Martyn in the north, Daniel Corrie in Agra, T. F. Middleton in Calcutta, and Reginald Heber all over India, were eagerly using their opportunities. In 1830 ten societies with 106 stations and 147 agents were at work; 1834 saw the founding of the Basel Mission on the west coast, the American Mission in Madura, the American Presbyterian Mission in Ludhiana. It would be impossible to trace in detail the work done by the different societies since Carey's time. The task as it presented itself may be analysed as follows: (1) to replace the caste system and especially the oppressive supremacy of the Brahmins by a spirit of universal brotherhood and the establishment of social and religious liberty; (2) to correct and raise the standard of conduct; (3) to attack polytheistic idolatry with its attendant immoralities; (4) to replace the pantheistic by a theistic standpoint; (5) to elevate woman and the pariah. Besides these matters which concerned Hinduism there was the problem of converting sixty million Mahommedans. The chief methods adopted have been the following: (1) vernacular preaching in the large towns and on itineraries through the rural districts, a work in which native evangelists guided by Europeans and Americans played a large part. (2) Medical missions, which have done much to break down barriers of prejudice, especially in Kashmir under Dr Elmslie of the Church Missionary Society, and in Rajputana at Jaipur under Dr Valentine of the United Presbyterians. (3) Orphanages, in which the Roman Catholics led the way and have maintained their lead. (4) Vernacular schools, a good example of which is seen in the American Board's Madura Mission. (5) English education, in which the missionary societies have amply supplemented the efforts of the government, outstanding examples being the Madras Christian College (Free Church of Scotland), so long connected with the name of Dr William Miller, the General Assembly of Scotland's Institution at Calcutta, founded by Duff, Wilson College, Bombay (Free Church of Scotland), and St Joseph's College (Roman Catholic) at Trichinopoly. Work of this kind is followed up in some centres by lectures and conversations with educated Hindus. The Haskell Lectureship, which grew out of the Parliament of Religions in Chicago, belongs here. (6) Female education and zenana work. (7) Uplifting work among the Panchamas or low-castes, which has been strikingly successful among the Malas (American Baptists) and the Madigas (London Missionary Society) of the Telugu-speaking country, who come in mass movements to the Christian faith. (8) Missions among aboriginal tribes, *e.g.* the Kols and Santals of Chota Nagpur (Berlin Gossner Mission and the Society for the Propagation of the Gospel), and the tribes of the Khassia Mountains east of Bengal (Welsh Calvinistic Methodists) (9) Christian literature, in which connexion the name of Dr John Murdoch will always be honourably remembered. (10) Pastoral work and the care of the churches.

The great changes that have been wrought in India, politically, commercially, intellectually and religiously, by the combined action of the British government and the Christian missions, are evidenced among other tokens by the growth of such societies as the Arya Samaj and the Brahmo Samaj. Orthodox Hindus, especially those whose social status and very livelihood are imperilled by the revolution, have shown their alarm either by open opposition, subjecting converts to every sort of caste coercion, or by methods of defence, *e.g.* Hindu tract societies and young men's associations, which are modelled on

Christian organizations. A counter reformation can also be traced which attempts to revive Hinduism by purging it of its grossness and allegorizing its fables and legends. A new Islam is also a factor of the situation. Comparatively few converts have been made from Mahommedanism to Christianity, and these have been chiefly among the learned. But there is a wide prevalence of free-thinking, especially among the younger and educated classes of the community.

The special difficulties of mission work in India may be thus summarized. (1) Racial antipathy. (2) The speculative rather than experimental and practical nature of the Hindu consciousness—historical proofs make no appeal to him. (3) The lack of initiative: in a land where the joint family system is everywhere and all powerful, individualism and will-power are at a discount. (4) The ignorance and conservatism of the women. (5) An inadequate sense of sin. (6) The introduction of European forms of materialism and anti-Christian philosophy. Perhaps, too, the methods adopted by missionaries have not always been the wisest, and they have sometimes failed to remember the method of their Master, who came "not to destroy, but to fulfil." In spite, however, of all the difficulties, permanent and increasing results have been achieved along all the lines indicated above. The establishment of a strong native church is far from being the only fruit of the enterprise, but it is a fruit that can be gauged by statistics, and these are sufficiently striking. In a necessarily inadequate sketch it is impossible to give more than the barest mention to one or two other features of modern missionary achievement in India, *e.g.* the development of industrial schools, the establishment of a South India United Church, in which the Congregationalist agencies (London Missionary Society and American Board) and the Presbyterians have joined forces, and the endeavour to train an efficient and educated native ministry, which is being promoted especially at Serampur, where an old Danish degree-granting charter has been revived in what should become a Christian university, and at Bangalore, where Presbyterians, Congregationalists and Wesleyans collaborate to staff and maintain a united theological college. The government census for India and Burma (1901) gives a Christian population of 2,923,241 (native Christians 2,664,313) out of a total population of 294,361,056, or about 3%. The inclusion of Portuguese and French possessions would add about 350,000 to the Christian total. Though the number does not seem relatively high, it is significant when compared with that of former censuses—in 1872, 1,517,997; in 1881, 1,862,525 (increase 22·7%); in 1891, 2,284,380 (increase 22·6%); in 1901, 2,923,241 (increase of 28%). The increase of 28% between 1891 and 1901 has often been compared with the fact that the total population of India only registered an increase of 2½% in that decade. In the words of *The Pioneer*, "this is a hard fact which cannot be explained away", and "the most remarkable feature of the returns." The increase was shared by every province and state in India. In 1910 there were 4614 missionaries (including wives), representing 122 societies, 1272 Indian ministers, and 34,095 other native workers, including teachers and Bible-women.

The growth of the Protestant Native Christian community between 1851 and 1910 is shown in the following table:—

	Native Christian Community.		Communicants.			Native Agents.	
	Number.	Rate of Increase.	Number.	Rate of Increase.	Proportion of the Community.	Ordained.	Unordained Preachers.
		%		%	%		
1851	91,092	—	14,661	—	16·0	21	493
1861	138,731	52·3	24,976	70·3	18·0	97	1266
1871	224,258	61·6	52,816	111·4	23·5	225	1985
1881	417,372	86·1	113,325	114·5	27·1	461	2488
1890	559,661	34·0	182,722	61·2	32·6	797	3491
1900	854,867	52·8	301,699	65·1	35·3	—	—
1910	1,472,448	72·2	522,743	73·3	—	1,272	—

The Protestant community in India in 1910 was over a million strong, well distributed among the chief provinces, a fine spiritual force, easily first in female education, and rapidly growing in wealth, position and influence. A recent report of the Director of Public Instruction for the Madras Presidency says: "I have frequently called attention to the educational progress of the native Christian community. There can be no question, if the community pursues with steadiness the present policy of its teachers, that in the course of a generation it will have secured a preponderating position in all the great professions."

What India wants (as Nobili 300 years ago saw, and attempted, though by fatal methods of deceit, to supply) is a Christianity not foreign but native, not dissociated from the religious life of the land but its fulfilment. Though there are many Christians in India to-day, the Hindu still looks askance at Christianity, not because it is a religion but because it is foreign. "India is waiting for her own divinely appointed apostle, who, whether Brahmin or non-Brahmin, shall connect Christianity with India's religious past, and present it as the true Vedanta or completion of the Veda and thus make it capable of appealing to the Hindu religious nature."

It only remains to be said that the work of the missionaries individually and collectively has over and over again received the warmest recognition and praise from the highest officials of the Indian government.

China.[1]—The earliest Christian missionaries to China, as to India, were the Nestorians (*q.v.*). Their work and that of the Roman Church, begun as the result of Marco Polo's travels about 1290, faded away under the persecution of the Ming dynasty which came to power about 1350. The next attempt was that of the French Jesuits, following on the visit and death of Xavier. They established themselves at Canton in 1582, and on the accession of the Manchu dynasty (1644) advanced rapidly. In 1685 there were three dioceses, Peking, Nanking and Macao, with a hundred churches. The Orthodox Eastern Church gained a footing in Peking in the same year, and established a college of Greek priests. Friction between Jesuits and Dominicans led to the proscription of Christianity by the emperor in 1724, missionaries and converts being banished. The story of modern missions in China begins with Robert Morrison (*q.v.*) of the London Missionary Society, who reached Canton in 1807, and not being allowed to reside in China entered the service of the East India Company. In 1813 he was joined by a colleague, William Milne, and in 1814 baptized his first convert. In 1829 came representatives of the American Board, in 1836 Peter Parker began his medical mission, and on the opening of the Treaty Ports the old edicts were withdrawn, and other societies crowded in to a field more than ample. After the war of 1856 a measure of official toleration was obtained, and the task of evangelizing the country was fairly begun. Though the missionaries were chiefly concentrated in the treaty ports they gradually pushed inland, and here the names of W. C. Burns, a Scottish evangelist, J. Hudson Taylor, the founder of the China Inland Mission, and James Gilmour, the apostle of Mongolia, are pre-eminent. But for more than half a century China seemed the most hopeless of mission fields. The upper classes were especially anti-foreign, and the whole nation vaunted its superiority to the rest of mankind. In 1857 there were only about 400 baptized Protestant Christians in the whole of China. Even after the removal of the edicts the old prejudices remained, and the missionaries were regarded as political emissaries, the forerunners of military aggression. Native Christians were stigmatized as traitors, "followers of the foreign devils." In 1870 there was a great outbreak concentrating in the massacres at Hankow and Tientsin; in 1891 at Hunan and in 1895 at Ku Cheng there were other attacks which were only preliminary to the Boxer uprising of 1899–1900, when 135 missionaries, besides 52 children and perhaps 16,000 native Christians, whose heroism will always be memorable, perished, often after horrible tortures. There is little doubt that this savage outburst was directed not against religious teaching as such, but against the introduction of customs and ideas which tended to weaken the old power of the mandarins over the people. These leaders skilfully seized upon every breach of tradition to inflame popular passion, attacking especially the medical work as a pretext for mutilation, the schools as hotbeds of vice, and the orphanages as furnishing material for witchcraft. Out of the agony, however, a new China was born. The growing power of Japan, seen in her wars with China and Russia, and the impotence of the Boxers against the European allies, made all classes in China realize their comparative impotence, and the central government began a series of reforms, reorganizing the military, educational, fiscal and political systems on Western lines. Educational reforms became especially insistent, and modern methods and studies supplanted the immemorial Confucian type. Students went in great numbers to Japan, Europe and America, and the old contempt and hostility toward things Western gave place to respect and friendliness. Early in the 19th century the missionaries had not been able to do much by way of education, but the new openings were seized with such power as was possible, and while in 1876 there were 289 mission schools with 4909 pupils, in 1910 there were 3129 schools with 79,823 scholars. More significant still is the way in which the foremost Chinese officials have turned to missionaries like Timothy Richard and Griffith John for assistance in guiding the new impulse. The universities of Oxford and Cambridge, under the inspiration of Lord William Cecil, were interesting themselves in 1910 in a scheme for establishing a Christian university in China.

---

[1] See A. H. Smith, *Chinese Characteristics*; *Village Life in China*; and J. C. Gibson, *Mission Problems and Mission Methods in South China*.

One of Morrison's contemporaries hoped that after a century of mission work there might possibly be 2000 Christians in China. That number was reached in 1865, and in 1910 there was a Protestant community of 214,546 church members and baptized Christians. These numbers are more than double what they were in 1900. In addition there are more than as many adherents.[1] The excellence of the converts, upon the whole, is testified to by travellers who really know the case; particularly by Mrs Bishop, who speaks of the "raw material" out of which they are made as "the best stuff in Asia." The total number of Protestant missionaries (including wives) in China in 1910 was 4175, one to about 1100 sq. m., or to more than 100,000 Chinese. There are over 12,000 Chinese evangelists, Bible-women, teachers, &c. The Roman Catholic returns give 902,478 members and 390,617 catechumens. The work is carried on by eleven societies or religious orders with over 40 bishops and 1000 European priests, mostly French. A large feature of the work is the baptism of children. An important concession was obtained in 1899 by the French minister at Peking, with a view to the more effective protection of the Roman missions. The bishops were declared "equal in rank to the viceroys and governors," and the priests "to the prefects of the first and second class"; and their influence and authority were to correspond. The Anglican bishops agreed to decline these secular powers, as also did the heads of other Protestant missions. It is alleged by some that the exercise of the powers gained by the Roman hierarchy was one cause of the Boxer outbreaks. Certainly their native adherents had their full share of persecution and massacre.

The Anglican Church is not so strong in China as in some other fields; the American Episcopalians were first in the field in 1835, followed by the Church Missionary Society (in 1844), which has had stirring success in Fu-Kien, and the Society for the Propagation of the Gospel in 1874. There are five dioceses, and in 1897 an episcopal conference was held in Shanghai. Since the Japanese War the Scottish and Irish Presbyterians have made wonderful progress in Manchuria; native evangelists do an increasing share of the work, and there is hardly any town or village without Christians. The London Mission has always been conspicuous for the contribution made by its agents to linguistic and literary knowledge, the name of James Legge being an outstanding example; it is now, in co-operation with other societies, earnestly taking up the new educational and medical openings. One of the most interesting features of missionary work in China is the comity that prevails among the workers of different societies and agencies. Thus in 1907 at the Centenary Conference in Shanghai, when many topics were discussed centring in the question of the native Chinese Church, a general declaration of faith and purpose was adopted, which, after setting out the things held in common, proceeded, "We frankly recognize that we differ as to methods of administration and of church government; that some among us differ from others as to the administration of baptism; and that there are some differences as to the statement of the doctrine of predestination, or the election of grace. But we unite in holding that these exceptions do not invalidate the assertion of our real unity in our common witness to the Gospel of the Grace of God." The conference reported, "We have quite as much reason to be encouraged by the net result of the progress of Christianity in China during the 19th century as the early Christians had with the progress of the Gospel in the Roman Empire during the first century."

Japan and Korea.—The Christian faith was brought to Japan by Portuguese traders in 1542, followed by Xavier in 1549. This great missionary was well received by the daimios (feudal lords), and though he remained only 2½ years, with the help of a Japanese whom he had converted at Malacca he organized many congregations. In 1581 there were 200 churches and 150,000 Christians; ten years later the converts numbered 600,000, in 1594 a million and a half. Then came a time of repression and persecution under Iyeyasu, whose second edict in 1614 condemned every foreigner to death, forbade the entry of foreigners and the return of Japanese who had left the islands, and extinguished Christianity by fire and sword. The reopening of the country came in 1859, largely through American pressure, and in May of that year two agents of the Protestant Episcopal Church began work at Nagasaki. They were followed by others from the Presbyterian and Reformed Churches, and by their great intellectual ability, patience and tact these pioneers (S. R. Brown, J. C. Hepburn and G. F. Verbeck), as the Marquis Ito said, contributed very largely to the progress and development of Japan in the days when she was first studying the outer world. They did an immense amount of preparatory work along evangelistic, medical and educational lines, and skilfully gathered the youths of the country around them. The accession of a new mikado in 1868 finally ended the old seclusion; financiers, engineers, artisans poured in from Western Europe, and from America came bands of teachers, largely under missionary influence. In 1869 the American Board (Congregational) sent its first band; in 1870 Verbeck was called on to organize a scheme for national education. In 1872 the first Japanese church was formed; in 1875 Joseph Neesima, who had been converted by a Russian missionary and then educated in America, founded a Christian Japanese College, the Doshisha, in the sacred city of Kyoto. Meanwhile the Christian calendar had been adopted and the old anti-Christian edicts removed. By 1889 there were 30,000 Protestant communicants. It was at this time that the nation, conscious of its new life, began to be restive under the supercilious attitude of foreign nations, and the feeling of irritation was shared by the native Christian communities. It showed itself in a desire to throw off the governance of the missionaries, in a criticism of Protestant creeds as not adapted to Japanese needs, and in a slackened growth numerically and intensively. After a period of stress and uncertainty, due very largely to the variety of denominational creed and polity, matters assumed an easier condition, the missionaries recognizing the national characteristics and aiming at guidance rather than control. The war with China in 1894 marked a new chapter and initiated a time of intense national activity; education and work for women went forward rapidly. Missionaries went through the island as never before, and their evangelistic work was built upon by Japanese ministers. In the war with Russia Japanese Christianity found a new opportunity; on the battlefield, in the camp, at home, Christian men were pre-eminent. In 1902 there were 50,000 church members; in 1910, 67,043; the total Protestant community in 1910 was about 100,000, and had an influence out of all proportion to its numbers; the Roman Church was estimated at 79,000, and the Orthodox Eastern Church (Russian) at 30,000.

No sketch, however brief, can omit a reference to the Anglican bishop of South Tōkyō, Edward Bickersteth (1850–1897), who from his appointment in 1886 guided the joint movement of English and American Episcopalians which issued in the Nippon Sei Kokwai or Holy Catholic Church of Japan, a national church with its own laws and its own missions in Formosa. In April 1907 the Conference of the World's Student Christian Federation (700 students from 25 different countries) met in Tōkyō, and received a notable welcome from the national leaders in administration, education and religion.

In Korea, the "Hermit Nation," or as the Koreans prefer to say, "The Land of the Morning Calm," Christianity was introduced at the end of the 18th century by some members of the Korean legation at Pekin who had met Roman Catholic missionaries. It took root and spread in spite of opposition until 1864, when an anti-foreign outbreak exterminated it. The door was re-opened by the treaties of 1882–1886, and even before that copies of the gospels had been circulated from the Manchuria side. The Methodist Episcopal Church and the Presbyterian Board, both of America, entered the country in 1885, and were soon joined by similar agencies from Canada and Australia. The Anglican Church began work in 1890, the work was thoroughly planned, the characteristics of the people were carefully considered, and the successes and failures of other mission-fields were studied as a guide to method. The medical work won the favour of the government, and so wisely did the missionaries act, that during all the turbulent changes since 1884 they escaped entanglement in the political disturbances and yet held the confidence of the people. The persistence and growth of Christianity among the Koreans is largely due to the fact that Christianity had not been superimposed on them as a foreign organization. They had built their own churches and schools, adopted their own forms of worship and phrased their own beliefs. Korea vies with Uganda as a triumph of modern missionary enterprise. In 1866 there were not more than 100 Christians; official returns in 1910 show 178,686 Protestants, including 72,000 church members and probationers; and 72,290 Roman Catholics. Theological colleges, normal training colleges and higher and lower grade schools bear witness to an activity and a success which are truly remarkable.

---

[1] See *Contemporary Review* (Feb. 1908), "Report on Christian Missions in China," by Mr F. W. Fox, Professor Macalister and Sir Alex. Simpson.

South-East Asia and the East Indies.—The work of Christian missions in this area has had the double advantage of freedom from political and social unrest, and of comparatively little overlapping, each country as a rule being taken over by a single society. In Burma the American Baptists, whose work began with Adoniram Judson in 1813, are conspicuous, and have had marked success among the Karens or peasant class, where the pioneer was George Dana Boardman (1827). The Karen Christian communities are strong numerically and have a good name for self-support. The Baptists have also stations in Arakan and Assam where they link up with the Welsh Calvinistic Methodists (1845). The Society for the Propagation of the Gospel and the Methodist Episcopal Church work in and around Rangoon. In Siam again the Americans, especially the Presbyterians, have been most prominent. Medical work made an impression on the people and won the favour of the government, which has always been cordial and has employed missionaries as court-tutors. Buddhism is at its best at Siam, and this and the enervating climate are responsible for the comparatively small direct success of Christian propaganda in Siam proper. In the Laos country to the north, however, much more has been done, and a healthy type of Christian community established. Native workers have done something to carry the Gospel into the French colonies of Tongking and Annam. Here the Roman missions are very extensive, and have over a million adherents, despite violent persecution before the French occupation.

The peninsula and archipelago known as *Malaysia* presents a remarkable mingling of races, languages and beliefs. Tatar, Mahommedan and Hindu invasions all preceded the Portuguese who brought Roman Catholicism, and the Dutch who brought Protestantism. This last resulted in a great number of nominal conversions, as baptism was the passport to government favour, and church membership was based on the learning of the Decalogue and the Lord's Prayer, and on the saying of grace at mealtimes. In the Straits Settlement the foundations of modern missionary effort were laid by the London Missionary Society pioneers who were waiting to get into China; they were succeeded by the Society for the Propagation of the Gospel (1856), English Presbyterians (1875), Methodist Episcopalians (1884), who have a fine Anglo-Chinese College at Singapore, and the Church of England Zenana Society (1900).

In the *Archipelago* most of the work has naturally been in the hands of the Netherlands Missionary Society (1812) and other Dutch agencies, who at first were not encouraged by the colonial government, but have since done well, especially in the Minahassa district of Celebes (150,000 members) and among the Bataks of Sumatra (Rhenish Mission). In Celebes and the Moluccas the work is now under the Colonial State Church. In Java the government has favoured Mahommedans (there is active intercourse between the island and Mecca), but there are some 25,000 Christians and a training school and seminary at Depok near Batavia. In Dutch Borneo the Rhenish Society is slowly making headway among the Dyaks; in British Borneo the Society for the Propagation of the Gospel (1848) and the Methodist Episcopalians occupy the field. The total number of Christians in British Malaysia and the Dutch East Indies is about 600,000 (including 57,000 Roman Catholics).

Western Asia and the Turkish Empire.[1]—The American Presbyterians and Congregationalists have the largest Protestant missions in these lands, working, however, mainly for the enlightenment and education of the Oriental Christians. With the same object, though on different lines, the archbishop of Canterbury's Assyrian Mission seeks to influence the Nestorians. The Roman Catholics have extensive missions in these countries, directed at winning adherents to the unity of the Holy See from the Oriental Churches, which are regarded as schismatic and heretical. In this enterprise there has been great advance in Egypt among the Copts, and in 1899 the Pope signalized "the resurrection of the Church of Alexandria" by appointing a Patriarch for Egypt, Libya and Nubia. Farther east, on the borders of Turkey and Persia, the Roman and Russo-Greek Churches compete for the adhesion of the Nestorians, Chaldeans and Armenians. The Franciscans, Dominicans, Lazarists and Jesuits are engaged in all these works. Direct work among Mahommedans is done, though with small result, by the North Africa Mission (non-denominational) and the Church Missionary Society. The Egypt, Palestine and Persia missions of the latter society have been largely reinforced and extended since 1884, medical work and women's work being especially prominent. Four cities in southern Persia are now occupied. Three missions just touch the border of *Arabia*, viz. the United Free Church of Scotland at Aden, founded by Ion Keith-Falconer (1856–1887) son of the 9th earl of Kintore and Arabic professor at Cambridge; an American Presbyterian Mission on the Persian Gulf; and the Church Missionary Society's Mission at Bagdad. The American Robert College at Constantinople and the work of the Friends' Missionary Association in Syria are honourable and successful enterprises. The chief difficulties have been (1) the antagonism of the officials of the Oriental churches, (2) the suspicion and hostility of Islam, (3) the jealousies, religious and political, connected with the Eastern Question.

Missions in Christian Lands.—Australia has been referred to already (see *South Seas*, above). In the Western Hemisphere we may distinguish the following: (1) *Early Roman Missions* began with the discovery of the continent and practically ceased in the middle of the 18th century. Conspicuous among their achievements was the conversion of Mexico, 200,000 converts being enrolled within six years after the capture of the capital (1521), and a million baptized by the Franciscans alone within thirty years. In South America the passive character of the population made them submissive alike to the Spanish government and the Roman faith. Their natural devotion and their susceptibility to pomp and ritual was a factor skilfully used by the priests, but hardly anything was done to strengthen their moral power. The influx of base European strata helped to reduce the whole continent south of Mexico in about a century to a level as low as that preceding the first mission. About 1600 the Franciscans and French Jesuits began their work in North America and among the Indians did a successful work marked by much heroism. They also enabled the Roman Church to keep its hold on the French colonists of Quebec and Montreal, and were pioneers in California. (2) *Modern Missions in North America.*—Missions among the Red Indian tribes in the North-West Territories of both the United States and Canada have long been carried on by several societies. The first workers were Thomas Mayhew, junior and John Eliot at Martha's Vineyard (1643) and Roxbury (1646). Bishop Whipple of Minnesota was justly called the Apostle of the Indians, so far as the work of the American Episcopal Church was concerned. In the Canadian North-West the Church Missionary Society's Missions have reached many tribes up to the shores of the Polar sea, and made some thousands of converts. Even the wandering Eskimos, thanks to the Moravians, are mainly Christians. The Anglican Church has nine dioceses in the province of Rupert's Land. The Roman Catholic missionaries also are scattered over these immense territories, and have a large number of Indian adherents. Besides the Oblates many are Jesuits from French Canada. The Russo-Greek Church has a mission in Alaska, dating from the time when it was Russian territory, and various American societies are also represented. The total number of Indians in British North America is 99,000, of whom about 27,000 are still pagan, and the rest are about equally divided between the Protestant and Roman Catholic Missions. (3) *Central and South America.*—Protestant missions to Indians here have been very limited. Von Weltz did something in Dutch Guiana (*c.* 1670), and the Moravians among the Arrawak Indians of Surinam (1738–1808). Since 1847 they have worked on the Mosquito coast of Central America. American Missions are at work in Mexico and adjacent countries. In the West India Islands the negro population has been reached by most of the larger British societies. The South American Missionary Society, founded by the ill-fated Captain Allen Gardiner, has much extended its work among the Indians of the interior of what has been well called "the Neglected Continent"; it has been specially successful among the Araucanians of Chile and the Paraguayan Chaco. Their work among the Fuegians drew a warm tribute from Charles Darwin. Several American missions are also at work. The Society for the Propagation of the Gospel has an important mission in British Guiana. But there are numerous heathen tribes never yet reached. The Roman Church, which is dominant throughout the continent, has been engaged in serious struggles with the anti-religious tendencies of the Republican governments, and *L'Année de l'Église* makes no mention of missions among the Indians. In fact the Pope in 1897 was obliged to send a severe rebuke to the clergy for their lack of consistency and zeal. Protestant societies have done much to bring the Bible to the knowledge of the nominally Roman Catholic population.

---

RESULTS OF MISSIONS

The Christian Church bases its missionary enterprise upon the spirit, the example, and the commandment of its Founder, and regards the duty as just the same whether the results be large or small. It appeals to common sense, saying in effect, "If it be a fact that a Divine Person came into the world to bless mankind, all men ought to know it, and have a right to know it. However much or (if you will) little a Buddhist or a Moslem may *need* to know of Christ, he certainly has a *claim* to be told of Him. The responsibility, if there be any, of believing, rests with the individual told; the responsibility of telling him rests with the Christian Church." On this view of the matter, results, however desirable, are no certain test of a mission doing its work. A mission in Persia, with its handful of converts, has, on this view, as much right to support and appreciation as a mission in southern India with its tens of thousands. Again, on the hypothesis that Christianity is true, the statistics at a particular period are no test of success at all. For in them *the dead are not counted*; and the converts who are already dead are—at least in respect of individual salvation—the surest of results. If, however, we are to take statistical returns for what they are worth, it is estimated that the Christians in heathen lands gathered by Protestant missions probably amount to five millions, and a similar total may be ascribed to Roman Catholic missions, making ten millions in all. This, however, includes adherents still under instruction for baptism, and their children. The inner circle of communicant members is hardly more than one-third of the total.

Missions are however a far greater thing after all than simple proselytism. It would require many a volume to tell of what they have done for civilization, freedom, the exploration of unknown regions, the bringing to light of ancient literatures, the founding of the science of comparative religion, the broadening of the horizon of Christian thought in the homelands, and the bringing of distant peoples into the brotherhood of nations. These are results that cannot be put into figures. While it is true that very diverse opinions are held concerning missions, it is indisputable that the most favourable testimonies come from those who have really taken the most pains to examine and understand their work. The one discouraging feature, from the Christian point of view, is the backwardness of Christendom in its great enterprise. If the Churches did their foreign work with the same energy which they throw into their home work, the results would be very different.

I.—STATISTICS OF THE GREAT RELIGIONS OF THE WORLD.

(From *The Blue Book of Missions*, 1907).

	558,862,000											

The figures given below are taken from a table compiled by Dr D. L. Leonard, and refer only to Protestant missions to non-Christian and non-Protestant peoples. The figures are for 1907, and should be compared with those in the *Statistical Atlas.* This list gives a total of 69 Foreign Missionary Societies, of which 34 are American, 19 British, 10 German, and 6 other societies. The statistics for these 69 societies may be grouped as follows:—

II.—SUMMARY OF PROTESTANT MISSIONARY WORK.

	AMERICAN.	BRITISH.	GERMAN.	OTHER SOCIETIES, viz. Paris Society, Swiss Romande, Netherlands Societies, Scandinavian Societies, &c.	Totals for Christendom.	Totals for 1895 (showing growth between 1895 and 1907).
Ordained Missionaries	1,911	1,980	932	912	5,735	4,028

III.—PROTESTANT MISSIONARY INCOME.

1895	£2,724,194	1906	£4,256,029
1900	£3,095,915	1907	£4,473,933[1]
1905	£3,932,377		

A world missionary conference was held at Edinburgh in June 1910, which aimed at making, on a scale far more comprehensive than had been previously attempted, a thorough and scientific study of the problems involved in the relation of Christianity to the non-Christian world. For two years preceding the conference eight representative commissions investigated the following questions:

---

[1] The *Statistical Atlas* (1910) puts it at £5,071,225, of which British and American societies each find about £2,000,000, and German societies £427,455.

(1) Carrying the Gospel to all the non-Christian world; (2) the Church in the mission field; (3) education in relation to the Christianization of national life; (4) the missionary message in relation to non-Christian religions; (5) the preparation of missionaries; (6) the home base of missions; (7) missions and governments; (8) co-operation and the promotion of unity. The reports on these subjects in eight volumes, together with a ninth volume giving the proceedings of the conference itself, and a statistical atlas, will for some time be the *vade mecum* of information on Christian missions, and precludes the need of any attempt at a bibliography here, an attempt which would indeed be doomed to failure. It may not, however, be out of place to call attention, in addition to literature already cited, to a few recent books, chiefly manuals, in several of which full lists of missionary books are given.

E. M. Bliss, *The Missionary Enterprise* (1908); E. Stock, *A Short Handbook of Missions* (1904); H. H. Montgomery, *Foreign Missions* (1904); T. Moscrop, *The Kingdom Without Frontiers* (1910); W. T. Whitley, *Missionary Achievement* (1908); S. L. Gulick, *The Growth of the Kingdom of God* (1897); B. Lucas, *The Empire of Christ*, a study of the missionary enterprise in the light of modern religious thought (1907); R. H. Malden, *Foreign Missions*, a study of some principles and methods (1910); G. Smith, *Short History of Christian Missions* (1897); G. Warneck, *Outline of a History of Protestant Missions* (1901; new German ed., 1910). See also J. S. Dennis, *Centennial Survey of Foreign Missions* (1902), *Christian Missions and Social Progress* (3 vols., 1897); G. Warneck, *Modern Missions and Culture* (1882); E. Stock, *History of the Church Missionary Society* (3 vols., 1899); J. B. Myers, *Centenary Volume of the Baptist Missionary Society* (1892); R. Lovett, *History of the London Missionary Society* (2 vols., 1899); J. Lowe, *Medical Missions, Their Place and Power*. A somewhat overlooked side of missions, viz. the "attempt to estimate the contribution of great races to the fulness of the Church of God," is presented in *Mankind and the Church*, edited by Bishop H. H. Montgomery (1907). *The Encyclopaedia of Missions* (2nd ed., 1904) edited by Bliss, Dwight and Tupper; *The Blue Book of Missions* by H. O. Dwight (1907); and the already mentioned *Statistical Atlas of Missions* (1910) by H. P. Beach, are all of the highest value. For Roman Catholic Missions see *Missiones Catholicae cura S. Congregationis de Propaganda Fide descriptae* (Romae, ex Typographia polyglotta S. C. de Prop. Fid. [official biennial publication]); Louvet, *Les Missions Catholiques* [*au*] *xix*ᵉ. *Siècle* (Lyon, Bureau des Missions Catholiques, 14 Rue de la Charité, 1900); Piolet, *Les Missions Catholiques Françaises* [*au*] *xix*ᵉ. *Siècle* (6 vols., Paris, A. (E. St.; H. T. A.; A. J. G.)

MISSISSIPPI, a South Central state of the United States, situated between 35° N. lat. and 31° N. lat., with its S.E. part extending to the Gulf of Mexico, the extreme southern point being in 30° 13′ N. lat. near the mouth of the Pearl River. On the E. the line is mostly regular, its extreme E. point being at 88° 7′ W. long. in the N.E. corner of the state; the W. boundary has its extreme W. point at 91° 41′ W. long. in the S.W. corner of the state. Mississippi is bounded N. by Tennessee, E. by Alabama, S. by the Gulf of Mexico and Louisiana, W. by Louisiana, from which it is separated by the Pearl River and by the Mississippi, and by Arkansas, from which also it is separated by the Mississippi. The total area is 46,865 sq. m., of which 503 sq. m. are water surface.

Physical Features.—Mississippi lies for the most part in the Mississippi embayment of the Gulf Coastal Plain. A feature of its surface is a strip of bottom land between the Mississippi and Yazoo rivers, known as the Yazoo Delta; it extends from north to south about 175 m., and has an average width of more than 60 m., and covers an area of about 7000 sq. m. With the exception of a few flat ridges running from north to south, it is so low that it requires, to protect it from overflows, an unbroken line of levees averaging 15 ft. in height; these were built and are maintained by the state in part from a special tax on the land and in part from the sale of swamp lands of the United States (under an act of 1850). Along the eastern border of this delta, and southward of it, along the Mississippi itself, extends a belt of hills or bluffs (sometimes called "cane-hills"), which is cut by deep ravines and, though very narrow in the north, has in the south an average width of about 10 m. East of the belt are level or gently rolling prairies, and along the Gulf Coast is a low, marshy tract. The highest elevations, from 800 to 1000 ft. above the sea, are on the Pontotoc ridge in Tippah and Union counties; and from this ridge there is an almost imperceptible slope south and west from the Appalachian Mountain system. Along the margins of valleys there are hills rising from 30 to 120 ft., but farther back from the water courses the differences of elevation are much less. The coast-line, about 85 m. long, is bordered by a beach of white sand, and broken by several small and shallow indentations, among which are St Louis, Biloxi, Pascagoula and Point aux Chenes bays; separated from it by the shallow and practically unnavigable Mississippi Sound is a chain of low, long and narrow sand islands, the largest of which are Petit Bois, Horn, Ship and Cat. The principal rivers are: the Mississippi on the western border, and its tributaries, the Yazoo and the Big Black; the Pearl and Pascagoula, which drain much of the southern portion of the state and flow into the Gulf; and the Tombigbee, which drains most of the north-eastern portion. The Pontotoc ridge separates the drainage system of the Mississippi from that of the Tombigbee; extending from the north-eastern part of the state southward, this ridge divides in Choctaw county, the eastern branch separating the drainage basin in the Pascagoula from that of the Pearl, and the western branch separating the drainage basin of the Pearl from that of the Big Black and the Mississippi. The Delta is drained chiefly by the Yazoo. A small area in the north-eastern corner of the state is drained northward by the Tennessee and the Hatchie. Each of the larger rivers is fed by smaller streams; their fall is usually gentle and quite uniform. The valleys vary in width from a few hundred yards to several miles. In the east of the state much of the valley of each of the larger streams is several feet above the stream's present high-water mark and forms the "hommock" or "second bottom" lands. Most of the rivers flowing into the Gulf are obstructed by sand-bars and navigable only during high-water from January to April. Oxbow lakes and bayous are common only in the Delta.

Geology.—The older formations are nearly all overlaid by deposits of the Quaternary period, which will be described last. In the extreme north-east are found the oldest rocks in the state—lower Devonian (the New Scotland beds of New York) and, not so old, an extension of the Lower Carboniferous which underlies the Warrior coalfields of Alabama, and which consists of cherts, limestones, sandstones and shales, with a depth of 800 to 900 ft. The strata here show some traces of the upheaval which formed the Appalachian Mountain chain. When this chain formed the Atlantic mountain-border of the continent excepting this north-eastern corner, Mississippi had not emerged from the waters of the ancient Gulf of Mexico. As the shore line of the Gulf slowly receded southward and westward, the sediment at its bottom gradually came to the surface, and constituted the Cretaceous and Tertiary formations. Wherever stratification is observed in these formations in Mississippi, it shows a dip west and south of 20 or 30 ft. to the mile.

The Cretaceous region includes, with the exception of the Lower Carboniferous, all that part of the state eastward of a line cutting the Tennessee boundary in 88° 50′ W. long., and drawn southward and eastward near Ripley, Pontotoc, and Starkville, crossing into Alabama in latitude 32° 45′. There are four formations of Cretaceous strata in Mississippi, defined by lines having the same general direction as the one just described. The oldest, bordering the Lower Carboniferous, is the Tuscaloosa formation of clays and sands arranged as follows: dark clays, thin lignite seams, lignitic clays, sands and chert, and light clays; this formation is 5–15 m. wide and reaches from about 33° 30′ on the Alabama boundary north to the Tennessee boundary. It is about 270 ft. thick. Tuscaloosa clays are used in the manufacture of pottery. Overlying the Tuscaloosa are the Eutaw sands, characterized by sandy laminated clays, and yellow, orange, red and blue sands, containing lignite and fossil resin. The Eutaw formation is a strip about 5 to 12 m. wide with a maximum depth of 300 ft. Westward to Houston and southward to about 32° 48′ on the Alabama boundary and occupying a much larger area than the other Cretaceous formations, is the Selma chalk, called "Rotten Limestone" by Hilgard; it is made up of a material of great uniformity,—a soft chalky rock, white or pale blue, composed chiefly of tenacious clay, and white carbonate of lime in minute crystals. Borings show that the thickness of this group varies from 350 ft. in the north to about 1000 ft. at Starkville. Fossils are abundant, and forty species are recorded. The latest Cretaceous is the Ripley formation, which lies west of the northern part of the last-named, and, about Scooba, in a small strip, the most southerly of the Cretaceous—it is composed of coarse sandstones, hard crystalline white limestones, clays, sands, phosphatic greensands, and dark-coloured, micaceous, glauconitic marls; its greatest thickness is about 280 ft. Its marine fossils are admirably preserved, and one hundred and eight species have been described.

Deposits of the Tertiary period form the basis of more than half the state, extending from the border of the Cretaceous westward nearly to the Yazoo Delta and the Mississippi Bottom, and southward to within a few miles of the Gulf coast. Seven formations (or groups) of the Tertiary strata have been distinguished in Mississippi. The oldest is the Midway limestone and clays in a narrow strip whose western limit is nearly parallel to the western boundary of the Selma chalk; it includes: the Clayton formation, characterized by the hard blue Turritella limestone (so named from the frequent fossil (*Turritella mortoni*); and Porters Creek (previously called Flatwoods) clay, which is grey, weathering white, and is occasionally overlain by grey fossiliferous sandstone. The Wilcox formation (called Lignitic by Hilgard, and named by Safford the Lagrange group) lies to the west of the last, and its western limit is from about 32° 12′ on the Alabama boundary about due north-west; in its north-westernmost part it is on the western edge of the Tertiary in this state. Its minimum depth is 850 ft. It is marked by grey clays and sands, lignitic fossiliferous clays, beds of lignite or brown coal, sometimes 8 ft. in thickness, and brownish clays. The siliceous Claiborne (or Tallahatta Buhrstone) formation lies south-westward from the last-named in a strip 10–30 m. wide, whose south-eastern extremity is the intersection of the 32nd meridian with the Alabama boundary, is characterized by beds of aluminous grey and white sandstone, aluminous and siliceous clay-stone, quartzitic sandstone, and green sand and marls. The calcareous Claiborne or Claiborne-Lisbon formation-group lies south of the last, in a wedge-like strip with the apex on the Alabama boundary; it is a series of clays and sands, richly fossiliferous. The Jackson formation south-west of the Lisbon beds, is made up chiefly of grey calcareous clay marls, bluish lignitic clays, green-sand and grey siliceous sands. *Basilosaurus* (or *Zeuglodon*) bones are found only in the Jackson marls, and other marine fossils are abundant. The minimum thickness of the formation is 240 ft. The Vicksburg formation lies next in order south-west, in a narrow strip of fairly regular width which alone of the Tertiary formations runs as far west as the Mississippi River; it is probably nowhere more than 110 ft. deep. It is characterized by semi-crystalline limestones and blue and white sandy marls. Marine fossils are very abundant in the marl. The Grand Gulf group, of formations of different ages, consisting of sands, sandstones and clays, and showing a few fossil plants, but no marine fossils, extends southward from the last to within a few miles of the coast, and is 750–800 ft. deep.

The older formation of the Quaternary period is the Lafayette (also called "Orange-sand" or "stratified drift"), which immediately overlies all the Cretaceous groups except the prairies of the Selma chalk, and all the Tertiary except the Porters Creek and Vicksburg formations and parts of the Jackson. Its depth varies from a few feet to over 200 ft. (in the southern part of the state), and it forms the body of most of the hills in the state. Its materials are pebbles, clays and sands of various colours from white to deep red, tinged with peroxide of iron, which sometimes cements the pebbles and sands into compact rocks. The shapes of these ferruginous sandstones are very fantastic—tubes, hollow spheres, plates, &c., being common. The name stratified drift has been used to indicate its connexion with the northern drift. The fossils are few, and in some cases probably derived from the underlying formations. Well-worn pebbles of amorphous quartz (agate, chalcedony, jasper, &c.) are found in the stratified drift along the western side of the Tertiary region of the state, and from Columbus northward. The second Quaternary formation is the Port Hudson, occurring within 20 m. of the Gulf coast, and, with alluvium, in the Yazoo Delta. Heavy clays, gravel and sands, containing cypress stumps, drift-wood and mastodon bones, are characteristic. The loess or bluff formation lies along the bluffs bordering the Bottom, nearly continuously through the state. Its fine-grained, unstratified silt contains the remains of many terrestrial animals, including fifteen mammals.

Fauna.—Among the more common species of game are squirrels, opossums, musk-rats, rabbits, racoons, wild turkeys, "partridges" (quail, or Bob White), geese, and ducks; deer, black bears, grey (or timber) wolves, black wolves and "wild cats" (lynx), once common, have become rare. Alligators inhabit the southern river-bottoms, and there are some rattlesnakes on the uplands. Among a great variety of song-birds the mocking-bird is prominent; the parakeet is found in the southern part of the state. Buffalo-fish, paddle-fish, cat-fish, drum, crappie, black bass, rock bass, German carp, sturgeon, pike, perch, eels, suckers and shrimp inhabit the waters of the Mississippi and its tributaries, and oysters, shrimp, trout, Spanish mackerel, channel bass, black bass, sheepshead, mullet, croakers, pompano, pin-fish, blue-fish, flounders, crabs and terrapin are obtained from the Mississippi Sound and the rivers flowing into it.

Flora.—Originally Mississippi was almost entirely covered with a growth of forest trees of large size, mostly deciduous; and in 1900 about seven-tenths of its area was still classed as timber-land. The north central part of the state, known as the "flat woods," is level and heavily forested. There are more than 120 species of trees in the state, 15 of oak alone. The most valuable species for lumber are the long-leaf pine which is predominant in the low southern third of the state, sometimes called the "cow-country"; the short-leaf pine, found farther north; the white oak, quite widely distributed; cotton-wood and red gum, found chiefly on the rich alluvial lands; and the cypress, found chiefly in the marshes of the Delta. The beautiful live oaks and magnolias grow only in the south of the state; the holly in the lowlands; and the finest species of pecan, in the Delta. The sassafras, persimmon, wild cherry and Chickasaw plum are found in all parts of the state. The grape, Ogeechee lime (*Nyssa capitata*) and pawpaw are also native fruits. Among indigenous shrubs and vines are the blackberry, dewberry, strawberry, yellow jasmine, mistletoe and poison-oak; and among medicinal herbs are horehound, ginger and peppermint. Here, too, grows Spanish moss, used by upholsterers.

Climate.—The southern latitude, the low elevation and the proximity to the Gulf of Mexico produce in southern Mississippi a rather mild and equable climate, but to the northward the extremes increase. The normal annual temperature for the state is 64° F.; on the coast it is 67° F., and on the northern border it is 61° F. During a period of twenty years, from January 1887 to December 1906, extremes of temperature at Biloxi, on the coast, ranged from 1° F. to 100° F.; during nearly the same period at Pontotoc, in the north-eastern part of the state, they ranged from −11° F. to 105° F. The greatest extremes recorded were −15° F. at Aberdeen, Monroe county, on the 13th of February 1899, and 107° F. at several places in July and August of different years. January is the coldest month, and July is the warmest. During the winter the normal temperature decreases quite steadily from south to north; thus the mean temperature in January at Biloxi is 51° F., at Meridian, in the east central part, it is 46° F., and at Pontotoc it is 43° F. But during the summer, temperatures are affected as much by altitude as by latitude, and the coast is cooled at night by breezes from the Gulf. The July mean is 82° F. at several places in the southern part of the state, and at Yazoo city, in the west central part, it is 83° F. The normal annual precipitation for Mississippi is about 51 in.; for the southern half, 54 in., and for the northern half, 49 in. An average of 4 in. of snow falls in the northern half, but south of Natchez snow is seldom seen. Nearly one-third of the rain falls in January, February and March; July, also, is one of the wet months. The driest season is in September and October. The prevailing winds are from the south-east; but the rain-bearing winds are chiefly from the south-west, and the high winds from the west and north-west.

Soils.—The most fertile soil is the alluvium of the Delta, deposited during the overflows of the Mississippi. Others that are exceedingly productive are the black calcareous loam of the prairies, the calcareous silt of the bluff belt along the eastern border of the Delta, and the brown loam of the tableland in the central part of the state. Of inferior quality are the yellow loam of the hills in the north-east and the sandy loam in the pine belt of the south. Throughout the southern portion sand is a large ingredient, and to the northward there is more or less lime.

Agriculture.—Mississippi is devoted largely to the cultivation of cotton. Of the total land area of the state, 18,240,736 acres (61·3 %) were, in 1900, included in farms, and the improved farm land increased from 4,209,146 acres in 1870 to 7,594,428 acres (41·6 % of all farm land) in 1900. After the abolition of slavery, farms greatly decreased in size and increased in number; the number grew from 68,023 in 1870 to 220,803 in 1900; the average size fell from 369·7 acres in 1860 to 82·6 acres in 1900. Of the total number of farms in 1900, 81,412 were worked by owners or part owners (60,585 by whites and 20,827 by negroes); 70,699 were worked by cash tenants (13,505 by whites and 57,194 by negroes); and 67,153 were worked by share tenants (16,748 by whites and 50,405 by negroes).

The acreage of cotton increased from 2,106,215 acres in 1879 to 3,220,000 in 1907; the yield increased from 936,111 bales in 1879 to 1,468,177 bales in 1907. Cotton is grown in every county of the state, but the large yields are in the Delta (Bolivar, Coahoma, Washington, Yazoo and Leflore counties), the greatest cotton-producing region of the world, and in Monroe, Lowndes and Noxubee counties on the Alabama border. The acreage of Indian corn in 1907 was 2,500,000 acres and the crop 42,500,000 bushels. The production of other cereals decreased during the latter half of the 19th century: oats, from 1,959,620 bushels in 1879 to 1,611,000 bushels in 1907; wheat, from 587,925 bushels in 1859 to 22,000 in 1907; rye, from 39,474 bushels in 1859 to 963 bushels in 1899, after which year the crop has been negligible; and rice, from 2,719,856 ℔ in 1849 to about 1,080,000 ℔ in 1907. The largest Indian-corn producing districts are nearly the same as those which produce the most cotton; oats and wheat are grown chiefly in the north-eastern quarter of the state, and rice in the south-western quarter.

Between 1850 and 1907 dairy cows increased from 214,231 to 330,000; other neat cattle from 519,739 to 589,000; sheep decreased from 304,929 to 181,000; swine decreased from 1,582,734 to 1,316,000; horses increased from 115,460 to 260,000, and mules from 54,547 to 279,000.

Sugar-cane is grown principally in the southern part of the state, but sorghum-cane is grown to some extent in nearly every county. Sweet potatoes, white potatoes and onions also are important crops. The greatest relative advance between 1889 and 1899 in any branch of agriculture was made in the growth of market-garden produce and small fruits; for old pine lands, formerly considered useless, had been found valuable for the purpose. The number of orchard trees increased nearly 100 % within the same decade. At Crystal Springs tomatoes were first successfully grown for the market (1874–1876). Orchard trees and grape-vines are widely distributed throughout the state, but with the exception of peaches their yield is greater in the northern portion.

Lumber.—Mississippi ranks high among the southern states in the production of lumber. Its timber-land in 1900 was estimated at 32,300 sq. m. From the extreme south most of the merchantable timber had been cut, but immediately north of this there were still vast quantities of valuable long-leaf pine; in the marshes of the Delta was much cypress, the cotton-wood was nearly exhausted, and the gum was being used as a substitute for it; and on the rich upland soil were oak and red gum, also cotton-wood, hickory and maple. The lumber and timber product increased in value from $1,920,335 in 1880 to $24,035,539 in 1905. Pine stumps and waste limbs are utilized, notably at Hattiesburg, for the manufacture of charcoal, tar, creosote, turpentine, &c.

Fisheries.—Fishing is a minor industry, confined for the most part to the Mississippi Sound and neighbouring waters and to the Mississippi and Yazoo rivers. The most valuable branch is the oyster

fishery on the reefs in the Sound, much developed since 1880. The shrimp fishery, too, grew during the same period. About 40% of the total catch of the state is made by the inhabitants of Harrison county on the Gulf of Mexico.

Minerals.—The mineral wealth of the state is limited. Clays and mineral waters are, however, widely distributed. Large quantities of mineral water, sulphur, chalybeate and lithia, bottled at Meridian, Raymond and elsewhere, are sold annually. The state contains deposits of iron, gypsum, marl, phosphate, lignite, ochre, glass-sand, tripoli, fuller's earth, limestones and sandstones; and there are small gas flows in the Yazoo Delta.

Manufactures.—The lack of mineral resources, especially of coal and iron, of a good harbour (until the improvement of Gulfport), and of an adequate supply of labour has discouraged most kinds of manufacturing. The value of the total factory product was $57,451,445 in 1905, when a little more than three-fourths was represented by lumber and timber products, cotton-seed oil and cake, and cotton goods. The leading manufacturing centres are Meridian, Vicksburg, Jackson, Natchez and Biloxi.

Transport.—Along the entire western border of the state the Mississippi River is navigable for river steamboats. On the southern border, the Mississippi Sound affords safe navigation for small coasting vessels, and from Gulfport (13 m. W.S.W. of Biloxi) to Ship Island, which has one of the best harbours on the entire Gulf Coast, the Gulf & Ship Island Railroad Company, with the co-operation of the United States Government, in 1901 began to dredge a channel 300 ft. wide and 19 ft. at mean low water, and to construct an anchorage basin (completed in 1906) at Gulfport, ½ m. long and ¼ m. wide, and 19 ft. deep. In June 1908 the maximum low-water draft of the channel and the basin was 19 ft. The Gulfport project reduced freight rates between Gulfport and the Atlantic seaboard cities and promoted the trade of Gulfport, which is the port of entry for the Pearl River customs district. Its imports for 1909 were valued at $82,028 and its exports at $8,581,471. The Yazoo, Tallahatchie, Yalobusha, Sunflower, Big Black, Pascagoula and Pearl rivers are also navigable to a limited extent. The first railway in Mississippi was completed from Vicksburg to Clinton in 1840, but the state had suffered severely from the panic of 1837, and in 1850 it had only 75 m. of railway. This was increased to 862 m. by 1860. The Civil War then interfered, and in 1880 the mileage was only 1127 m. During the next decade it was a little more than doubled, and at the close of 1908 it was 3916·85 m. The principal lines are the Illinois Central, the Yazoo & Mississippi Valley, the Southern, the Mobile & Ohio, the New Orleans & North-eastern, the Kansas City, Memphis & Birmingham, the Mobile, Jackson & Kansas City, the Alabama & Vicksburg, and the Gulf & Ship Island.

Population.—The population increased from 1,131,597 in 1880[1] to 1,289,600 in 1890, of 14% within the decade, and by 1900 it had grown to 1,551,270 (99·48% native-born), and by 1910 to 1,797,114. The density of population in 1900 was 33.5 per sq. m.; 641,200, or 41·3%, were whites; 907,630, or 58·5%, were negroes; 2203 were Indians, and 237 were Chinese; in eight counties of the Delta the ratio of negroes to whites was almost 7 to 1. The Indians are descendants of the Choctaw tribe; they are all subject to taxation, and most of them live in the east central part of the state. The principal religious denominations are the Baptist (371,518 in 1906) and the Methodist (212,105 in 1906). The cities and towns having a population in 1900 of 4000 or more were: Vicksburg, Meridian, Natchez, Jackson, Greenville, Columbus, Biloxi, Yazoo City, McComb and Hattiesburg.

Government.—The chief special object of the present constitution, adopted on the 1st of November 1890, was to preserve in a legal manner the supremacy of the whites over the ignorant negro majority. In addition to the ordinary suffrage qualifications of age, sex, and residence, the voter must have paid all taxes due from him for the two years immediately preceding the election, and he must be able to read any section of the constitution or "be able to understand the same when read to him, or give a reasonable interpretation thereof." The former provision, strengthened by a poll-tax for school purposes assessed on adult males, affects both white and blacks; the latter, owing to the discretion vested in the election officers, affects (in practice) mainly the blacks. The chief executive officials are the governor, lieutenant-governor, secretary of state, treasurer, auditor, attorney-general, and superintendent of education. All are chosen for terms of four years, and the governor, treasurer, and auditor are ineligible for immediate re-election. The method of election is peculiar, being based in part upon the national presidential model. Each county or legislative district casts as many electoral votes as it has members in the state house of representatives, and a majority of both the electoral and the popular vote is required. If no one has such a majority, the house of representatives chooses one of the two who have received the highest number of popular votes; but this is really a provision never executed, as the Democratic nominees are always elected without any serious opposition. The governor is empowered to call extraordinary sessions of the legislature, to grant pardons and reprieves, and to exercise a power of veto which extends to items in appropriation bills; a two-thirds majority of the legislature is necessary to pass a bill over his veto. His appointing power is not very extensive, as nearly all officials, except judges, are elected by popular vote.

The legislature consists of a senate and a house of representatives, chosen every four years. It meets in regular session quadrennially, in special sessions in the middle of the interval to pass the appropriation and revenue bills, and in extraordinary session whenever the governor sees fit to call it. Revenue measures may originate in either house, but a three-fifths vote in each is necessary to their enactment. The constitution goes into minute detail in prohibiting local, private and special legislation.

The judiciary consists of a supreme court of three judges, thirteen (1908) circuit courts, seven (1908) chancery courts, county courts and justice of the peace courts. Under the constitution of 1890 the governor, with the consent of the senate, appoints supreme court judges for a term of nine years, and circuit and chancery judges for four years. The local judicial authorities are the county board of supervisors of five members and the justices of the peace.

The other county officials are the sheriff, coroner, treasurer, assessor, surveyor and superintendent of education. The superintendent is chosen by the state board of education except in those counties (now all or nearly all) in which the legislature has made the office elective. The courts have interpreted this to mean that the manner of selection need not be uniform (*Wynn* v. *State*, 67 Miss. 312), a rule which would possibly apply to other local offices. The intention seemed to be to permit the appointment of officials in counties and districts where there was any likelihood of negro supremacy.

Mississippi has taken a leading part in the movement to bring about the removal of the common law disabilities of married women, the first statute for that purpose having been passed in 1839. Under the present constitution they are "fully emancipated from all disability on account of coverture," and are placed on an equality with their husbands in acquiring and disposing of property and in making contracts relative thereto. A divorce may be granted only to one who has lived for at least one year in the state; among the recognized causes for divorce are desertion for two years, cruelty, insanity or physical incapacity at time of marriage, habitual drunkenness or excessive use of opium or other drugs, and the conviction of either party of felony. The homestead of a householder (with a family) who occupies it may be held exempt from sale for the collection of debts other than those for purchase-money, taxes, or improvements, or for the satisfaction of a judgment upon a forfeited recognizance or bail-bond, but a homestead so exempted is limited to $3000 in value and to 160 acres of land. A considerable amount of personal property, including furniture, a small library, provisions, tools, agricultural implements, livestock and the proceeds of a life insurance policy, is also exempt from seizure for the satisfaction of debts. Since 1909 the sale of intoxicating liquors has been prohibited by statute.

Penal and Charitable Institutions.—The penitentiary at Jackson was established under an Act of 1836, was erected in 1838–1839, was opened in 1840, was burned by the Federals in 1863, and was rebuilt in 1866–1867. The board of control is composed of the governor, attorney-general and the three railroad commissioners. The convict lease system was abolished by the constitution of 1890 (the provision to take effect on the 31st of December 1894), and state farms were purchased in Rankin, Hinds and Holmes counties. As these were insufficient to give employment to all the prisoners, some were put to work on Yazoo Delta plantations on partnership contracts. Under an act of 1900, however, 13,889 acres of land were purchased in Sunflower county; and there and at Tchula, Holmes county, and at Oakley, Hinds county, the negro convicts—the white convicts are on the Rankin county farm—are kept on several large plantations, with saw-mills, cotton gins, &c. Under a law of 1906 these farm penitentiaries are controlled by a board of three trustees, elected by the people; they are managed by a superintendent.

---

[1] The population at each of the preceding censuses was: 8850 in 1800; 40,352 in 1810; 75,448 in 1820; 136,621 in 1830; 375,651 in 1840; 606,526 in 1850; 791,305 in 1860; and 827,922 in 1870.

appointed once every four years by the governor. The charitable institutions of the state are supervised by separate boards of trustees appointed by the governor. The state insane hospital, opened at Jackson in 1856 (act of 1848), in time became overcrowded and the East Mississippi insane hospital was opened, 2 m. west of Meridian in 1885 (act of 1882). The state institution for the education of the deaf and dumb (1854) and the state institution for the blind (1848) are at Jackson. State aid is given to the hospitals at Vicksburg and Natchez.

Education.—Educational interests were almost entirely neglected during the colonial and territorial periods. The first school established in the state was Jefferson College, now Jefferson Military College, near Natchez, Adams county, incorporated in 1802. Charters were granted to schools in Claiborne, Wilkinson and Amite counties in 1809–1815, and to Port Gibson Academy and Mississippi College, at Clinton, in 1826. The public school system, established in 1846, never was universal, because of special legislation for various counties; public education was retarded during the Civil War and the Reconstruction period (when immense sums appropriated for schools were grossly mismanaged), but conditions gradually improved after 1875, especially through the concentration of schools. The sessions are still too short, teachers are poorly paid and attendance is voluntary. The long lack of normal training for white teachers (from 1870 to 1904 there was a normal school for negroes at Holly Springs) lasted until 1890, when a teacher's training course was introduced into the curriculum of the state university. There are separate schools for whites and blacks, and the equipment and service are approximately equal, although the whites pay about nine-tenths of the school taxes. The schools are subject to the supervision of a state superintendent of public education and of a board of education, composed of the superintendent, the secretary of state, and the attorney-general, and within each county to a county superintendent. The schools are supported by a poll-tax, by general appropriations, by local levies, and by the Chickasaw school fund. An act of Congress of the 3rd of March 1803 reserved from sale section sixteen of the public lands in each township for educational purposes. When the Chickasaws ceded their lands to the national government, in 1830 and in 1832, the state made a claim to the sixteenth sections, and finally in 1856 received 174,550 acres —one thirty-sixth of the total cession of 6,283,804 acres. The revenue derived from the sales and leases of this land constitutes an endowment fund upon which the state as trustee pays 6% interest. It is used for the support of the schools in the old Chickasaw territory in the northern part of the state.

Among the institutions for higher education are the university of Mississippi (chartered 1844; opened 1848), at Oxford, which was opened to women in 1882; the Agricultural and Mechanical College (opened 1880), at Agricultural College, near Starkville, Oktibbeha county; the Industrial Institute and College for Girls (opened 1885), at Columbus; and the Alcorn Agricultural and Mechanical College for negroes (1871; reorganized in 1878), at Westside. In 1819 Congress granted thirty-six sections of public land for the establishment of a university. This land was sold in 1833 for $277,332.52, but the entire sum was lost in the failure of the Planters' Bank in 1840. In 1880 the state assumed liability for the full amount plus interest, and this balance, $544,061.23, now constitutes an endowment fund, upon which the state pays 6% interest. Congress granted another township (thirty-six sections) for the university in 1892, and its income is supplemented by legislative appropriations for current expenses and special needs. The two agricultural and mechanical colleges were founded by the sale of public lands given by Congress under the Morrill Act of 1862. An agricultural experiment station established in 1887 under the Hatch Act, is at Agricultural College; and there are branch experiment stations at McNeill, Pearl River county (1906), near Holly Springs, and at Stoneville, near Greenville.

Finance.—The chief sources of revenue are taxes on realty, personalty and corporations, a poll-tax, and licences. The more important expenditures are for public schools, state departments, educational and charitable institutions and pensions for Confederate veterans. The early financial history of the state is not very creditable. The Bank of Mississippi, at Natchez, incorporated by the Territorial legislature in 1809, was rechartered by the state in 1818, and was guaranteed a monopoly of the banking business until 1840. In violation of this pledge, and in the hope that a new bank would be more tractable than the Bank of Mississippi, the Planters' Bank was established at Natchez, in 1830, with a capital of $3,000,000, two-thirds of which was subscribed by the state. During the wild era of speculation which followed (especially in 1832—upon the opening of the Chickasaw Cession to settlement) a large number of banks and railroad corporations with banking privileges were chartered. The climax was reached in 1838 with the incorporation of the Union Bank. This, the most pretentious of all the state banks of the period, was capitalized at $15,500,000. The state subscribed $5,000,000, which was raised on bonds sold to Nicholas Biddle, president of the United States Bank of Pennsylvania. As the Union Bank was founded in the midst of a financial panic and was mismanaged, its failure was a foregone conclusion. Agitation for repudiation was begun by Governor A. G. McNutt (1801–1848), and that question became the chief issue in the gubernatorial campaign of 1841, Tilghman M. Tucker (1802–1859), the Democratic candidate, representing the repudiators and David O. Shattuck, Whig, representing the anti-repudiators. The Democrats were successful, and the bonds were formally repudiated in 1842. In 1853 the High Court of Appeals and Errors of the state in the case of *Mississippi* v. *Hezion Johnson* (35 *Miss. Reports*, 625) decided unanimously that nothing could absolve the state from its obligation. The decision was disregarded, however, and in the same year the Planters' Bank bonds were also repudiated by popular vote. These acts of repudiation were sanctioned by the constitution of 1890. The $7,000,000 saved in this manner has doubtless been more than offset by the additional interest charges on subsequent loans, due to the loss of public confidence. Mississippi suffered less than most of the other Southern states during the Reconstruction period; but expenditures rose from $463,219.71 in 1869 to $1,729,046.34 in 1871. At the close of the Republican régime in 1876 its total indebtedness was $2,631,704.24, of which $814,743 belonged to the Chickasaw fund (see above) and $718,946.22 to the general school fund. As the principal of these funds is never to be paid, the real debt was slightly over $1,000,000. On the 1st of October 1907 the payable debt was $1,253,029.07, the non-payable $2,336,197.58,[1] a total of $3,589,226.65. Since the Civil War the banking laws have become more stringent and the national banks have exercised a wholesome influence. There were, in 1906, 24 national banks and 269 state banks, but no trust companies, private banks or savings banks.

History.—At the beginning of the 16th century the territory included in the present state of Mississippi was inhabited by three powerful native tribes: the Natchez in the south-west, the Choctaws in the south-east and centre, and the Chickasaws in the north. In addition, there were the Yazoos in the Yazoo valley, the Pascagoulas, the Biloxis, and a few weaker tribes on the borders of the Mississippi Sound. The history of Mississippi may be divided into the period of exploration (1540–1699), the period of French rule (1699–1763), the period of English rule (1763–1781), the period of Spanish rule (1781–1798), the territorial period (1798–1817), and the period of statehood (1817 seq.).

Hernando de Soto (*q.v.*) and a body of Spanish adventurers crossed the Tombigbee river, in December 1540, near the present city of Columbus, marched through the north part of the state, and reached the Mississippi river near Memphis in 1541. In 1673 a French expedition organized in Canada under Jacques Marquette and Louis Joliet sailed down the Mississippi to the mouth of the Arkansas, and nine years later (1682) René Robert Cavelier, sieur de la Salle, reached the mouth of the river, took formal possession of the country which it drains, and named it Louisiana in honour of Louis XIV. The first European settlement in Mississippi was founded in 1699 by Pierre Lemoyne, better known as Iberville, at Fort Maurepas (Old Biloxi) on the north side of Biloxi Bay, in what is now Harrison county. The site proving unfavourable, the colony was transferred to Twenty-seven Mile Bluff, on the Mobile River, in 1702, and later to Mobile (1710). The oldest permanent settlements in the state are (New) Biloxi (*c.* 1712), situated across the bay from Old Biloxi and nearer to the Gulf, and Natchez or Fort Rosalie (1716). During the next few years Fort St Peter and a small adjoining colony were established on the Yazoo River in Warren county, and some attempts at settlement were made on Bay St Louis and Pascagoula Bay. The efforts (1712–1721) to foster colonization and commerce through trading corporations established by Antoine Crozat and John Law failed, and the colony soon came again under the direct control of the king. It grew very slowly, partly because of the hostility of the Indians and partly because of the incapacity of the French as colonizers. In 1729–1730 the Natchez tribe destroyed Fort St Peter, and some of the small outposts, and almost destroyed the Fort Rosalie (Natchez) settlement.

At the close of the Seven Years' War (1763) France ceded to Great Britain all her territory east of the Mississippi except New Orleans, and Spain ceded Florida to Great Britain. By a royal proclamation (Oct. 7, 1763) these new possessions were divided into East Florida and West Florida, the latter lying S. of the 31st parallel and W. of the Chattahoochee and Apalachicola rivers. Crown orders of 1764 and 1767 extended the limits N. to a line due E. from the mouth of the Yazoo at about 32° 28′ N. lat. Under English rule there was an extensive immigration into this region from England, Ireland, Georgia and South Carolina. A settlement was made on the Big Black, 17 m. from its mouth, in 1774 by Phineas Lyman (1716–1774) of Connecticut and other "military adventurers," veterans of the Havana campaign of 1762; this settlement was loyal during the War of Independence. Spain took military possession in 1781, and in the Treaty of Paris (1783) both of the Floridas were ceded back to her. But Great Britain recognized the claims of the United States to the territory as far south as the 31st parallel, the line of 1763. Spain adhered to the line of 1764–1767, and retained possession of the territory in dispute. Finally, in the treaty of San Lorenzo el Real (ratified 1796) she accepted the 1763 (31°) boundary, and withdrew her troops in 1798. Mississippi Territory was then organized, with Winthrop Sargent as governor. The territorial limits were extended on the north to the state of Tennessee in 1804 by the acquisition of the west cessions of South Carolina and Georgia, and on the south to the Gulf of Mexico by the seizure of West Florida in 1810–1813,[1] but were restricted on the east by the formation of the Territory of Alabama in 1817. Just after the uprising of 1729–1730 the French, with the help of the Choctaws, had destroyed the Natchez nation, and the shattered remnants were absorbed by the neighbouring tribes. The Chickasaws ceded their lands to the United States in 1816 and the Choctaws theirs in 1830–1832; and they removed to the Indian Territory. The smaller tribes have been exterminated, absorbed or driven farther west.

---

[1] The increase is due mainly to the assumption of the university obligations in 1880.

An Enabling Act was passed on the 1st of March 1817, and the state was formally admitted into the Union on the 10th of December. The first state constitution (1817) provided a high property qualification for governor, senator and representative, and empowered the legislature to elect the judges and the more important state officials. In 1822 the capital was removed to Jackson from Columbia, Marion county.[2] The constitution of 1832 abolished the property qualification for holding office and provided for the popular election of judges and state officials. Mississippi thus became one of the first states in the Union to establish an elective judiciary.[3] The same constitution prohibited the importation of negro slaves from other states; but this prohibition was never observed, and the United States Supreme Court held that it was ineffective without an act of the legislature. On the death of John C. Calhoun in 1850 the state, under the leadership of Jefferson Davis, began to rival South Carolina as leader of the extreme pro-slavery States' Rights faction. There was a brief reaction: Henry Stuart Foote (1800–1880), Unionist, was elected governor in 1851 over Davis, the States' Rights candidate, and in the same year a Constitutional Convention had declared almost unanimously that "the asserted right of secession" . . . "is utterly unsanctioned by the Federal Constitution." But the particularistic sentiment continued to grow. An ordinance of secession was passed on the 9th of January 1861, and the constitution was soon amended to conform to the new constitution of the Confederate States. During the Civil War battles were fought at Corinth (1862), Port Gibson (1863), Jackson (1863) and Vicksburg (1863). In 1865 President Johnson appointed as provisional governor William Lewis Sharkey (1797–1873), who had been chief justice of the state in 1832–1850, and a convention which assembled on the 14th of August recognized the "destruction" of slavery and declared the ordinance of secession null and void. The first reconstruction legislature met on the 16th of October 1865, and at once proceeded to enact stringent vagrancy laws and other measures against the freedmen; these laws the North interpreted as an effort to restore slavery. Under the Reconstruction Act of the 2nd of March 1867 Mississippi with Arkansas formed the fourth military district, commanded successively by Generals E. O. C. Ord (1867), Alvan C. Gillem (1868) and Irvin McDowell (June–July 1868), and by Gillem (1868–1869) and Adelbert Ames (1869–1870). The notorious "Black and Tan Convention" of 1868 adopted a constitution which conferred suffrage upon the negroes and by the imposition of test oaths disfranchised the leading whites. It was at first rejected at the polls, but was finally ratified in November 1869 without the disfranchising clauses. The fourteenth and fifteenth amendments to the Federal Constitution were ratified in 1870, and the state was formally readmitted into the Union on the 23rd of February of that year.

From 1870 to 1875 the government was under the control of "carpet-baggers," negroes and the most disreputable element among the native whites. Taxes were increased—expenditure increased nearly threefold between 1869 and 1871—and there was some official corruption; but the state escaped the heavy burden of debt imposed upon its neighbours, partly because of the higher character of its reconstruction governors, and partly because its credit was already impaired by the repudiation of obligations contracted before the war. The Democrats carried the legislature in 1875, and preferred impeachment charges against Governor Adelbert Ames (b. 1835), a native of Maine, a graduate of the United States Military Academy (1861), a soldier in the Union army, and military governor of Mississippi in 1868–1870. The lieutenant-governor, A. K. Davis, a negro, was impeached and was removed from office; T. W. Cardoza, another negro, superintendent of education under Ames, was impeached on twelve charges of malfeasance, but was permitted to resign. Governor Ames, when the impeachment charges against him were dismissed on the 29th of March 1876, immediately resigned. The whites maintained their supremacy by very dubious methods until the adoption of the constitution of 1890 made it no longer necessary. The state has always been Democratic in national politics, except in the presidential elections of 1840 (Whig) and 1872 (Republican). The electoral vote was not counted in 1864 and 1868.

GOVERNORS

Territorial Period (1798–1817).		
Winthrop Sargent		1798–1801
William C. C. Claiborne		1801–1805
Robert Williams		1805–1809
David Holmes		1809–1817
Statehood Period (1817 seq.).		
David Holmes	Democrat	1817–1820
George Poindexter	,,	1820–1822
Walter Leake	Democrat (died in office)	1822–1825
Gerard C. Brandon (ad int.)	Democrat	1825–1826
David Holmes	Democrat (resigned)	1826
Gerard C. Brandon (ad int. 1826–1828)		1826–1832
Abram M. Scott	Democrat (died in office)	1832–1833
Charles Lynch [4] (ad. int.)	Democrat	1833
Hiram G. Runnels	,,	1833–1835
John Anthony Quitman (ad int.)	Whig	1835–1836
Charles Lynch	Democrat	1836–1838
Alexander Gallatin McNutt	,,	1838–1842
Tilghman M. Tucker	,,	1842–1844
Albert Gallatin Brown	,,	1844–1848
Joseph W. Matthews	,,	1848–1850
John Anthony Quitman [5]	,,	1850–1851
John Isaac Guion [6] (ad int.)	,,	1851
James Whitfield (ad int.)	,,	1851–1852
Henry Stuart Foote	Unionist	1852–1854
John Jones Pettus [7] (ad int.)	Democrat	1854
John J. McRae	,,	1854–1857
William McWillie	,,	1857–1859
John Jones Pettus	,,	1859–1863

[1] South Carolina ceded its western lands to the United States in 1787 and Georgia in 1802. The government added them to Mississippi in 1804. The seizure of West Florida was supplemented by the treaty of 1819–1821, in which Spain surrendered all of her claims.

[2] The seats of government have been Natchez (1798–1802), Washington (1802–1817), Natchez (1817–1821), Columbia (1821–1822), Jackson (1822 seq.).

[3] This system proved unsatisfactory, and in 1869 was abandoned.

[4] Under the constitution of 1832 the president of the senate succeeded the governor in case of a vacancy.

[5] Governor Quitman resigned because of charges against him of aiding Lopez's expedition against Cuba.

[6] On the 4th of November the term for which Guion had been elected as a senator expired and he was succeeded in the governorship by Whitfield, elected by the senate to be its president.

[7] Served from the 5th of January (when Foote resigned) to the 10th, when McRae was inaugurated.

Charles Clark[1]	Democrat	1863–1865
William Lewis Sharkey	Provisional	1865
Benjamin Grubb Humphreys[2]	Republican	1865–1868
Adelbert Ames	Republican (Military Governor)	1868–1870
James Lusk Alcorn[3]	Republican	1870–1871
Ridgley Ceylon Powers (ad int.)	,,	1871–1874
Adelbert Ames[4]	,,	1874–1876

See T. A. Owen, "A Biography of Mississippi," in the *Annual Report of the American Historical Association, 1899*, i. 633-828 (Washington, 1900); "Report of the Mississippi Historical Commission" in the *Publications of the Mississippi Historical Society*, v. 52-310 (Oxford, Miss., 1902). J. F. H. Claiborne's *Mississippi as a Province, Territory and State* (Jackson, 1880), gives the best account of the period before the Civil War. R. Lowry and W. H. McCardle, *History of Mississippi* (New York, 1893), is useful for local history. Of most value for the history are the writings of P. J. Hamilton, J. W. Garner and F. L. Riley. Hamilton's *Colonial Mobile* (Boston and New York, 1898), and the *Colonization of the South* (Philadelphia, 1904) are standard authorities for the French and English periods (1699–1781). Garner's *Reconstruction in Mississippi* (New York, 1902) is judicial, scholarly and readable. Most of Riley's work is in the *Publications of the Mississippi Historical Society* (Oxford, 1898 seq.), which he edited; see his *Spanish Policy in Mississippi after the Treaty of San Lorenzo*, i. 50-66; *Location of the Boundaries of Mississippi*, iii. 167-184; and *Transition from Spanish to American Rule in Mississippi*, iii. 261-311. There is much material in the *Encyclopaedia of Mississippi History* (2 vols., Madison, Wisconsin, 1907), edited by Dunbar Rowland. There is a state Department of Archives and History.

MISSISSIPPI[5] RIVER, the central artery of the river system which drains the greater part of the United States of America lying between the Appalachian Mountains on the east and the Rocky Mountains on the west. It rises in the basin of Itasca Lake, in northern Minnesota, and flows mostly in a southerly direction to the Gulf of Mexico. In the region of its headwaters are numerous lakes which were formed by glacial action, but the river itself was old before the glacial period, as is shown by the crumbling rocks on the edges of the broad and driftless valley through which it flows along the S.E. border of Minnesota and the S.W. border of Wisconsin, in contrast with the precipitous bluffs of hard rock on the edges of a valley that is narrow and steep-sided farther down where the river was turned from its ancient course by the glacier. So long as the outlet of the Great Lakes through the St Lawrence Valley was blocked by the icy mass, they were much larger than now and discharged through the Wabash, Illinois and other rivers into the Mississippi. Below the glaciated region, that is from southern Illinois to the Gulf, the river had carved before the close of the glacial period a flood-plain varying in width from 5 to 80 m., but this has been filled to a depth of 100 ft. or more with alluvium, and in the post-glacial period an inner valley has been formed within the outer one. The total length of the river proper from the source near Lake Itasca to its mouth in the Gulf of Mexico is 2553 m.; but the true source of the river is at the fountain-head of the Missouri, in the Rocky Mountains, on the S.W. border of Montana, 8000 ft. above the sea, and from this source there is a continuous stream to the Gulf which is 4221 m. long—the longest in the world. The Mississippi and its tributaries have more than 15,000 m. of navigable waterways and drain an area of approximately 1,250,000 sq. m. The system extends through the heart of the continent and affords a direct line of communication between temperate and tropical regions. Certain physical and hydrographic features, however, make the regulation and control of the Mississippi below the influx of the Missouri an exceedingly difficult problem.

The Upper Mississippi, that is the Mississippi from its source to the mouth of the Missouri, drains 173,000 sq. m., over which the annual rainfall averages 34·7 in., and its discharge per second into the Lower Mississippi varies from 25,000 cub. ft. to 550,000 cub. ft. The Missouri drains 528,000 sq. m., over which the annual rainfall averages 19·6 in., and its discharge per second into the Mississippi varies from 25,000 cub. ft. to 600,000 cub. ft. The Ohio drains 214,000 sq. m., over which the annual rainfall averages 43 in., and its discharge per second varies from 35,000 cub. ft. to 1,200,000 cub. ft. The Arkansas drains 161,000 sq. m., over which the annual rainfall averages 28·3 in., and its discharge per second varies from 4000 cub. ft. to 250,000 cub. ft. The Red drains 97,000 sq. m., over which the annual rainfall averages 38·3 in., and its discharge per second varies from 3500 cub. ft. to 180,000 cub. ft. These and a few smaller tributaries produce a river which winds its way from Cape Girardeau, Missouri, to the passes through a flood plain averaging about 40 m. in width and having a general southern slope of 8 in. to the mile. The general lateral slope towards the foothills is about 6 in. in 5000 ft., but the normal fall in the first mile is about 7 ft. Thus the river sweeps onward with great velocity, eroding its banks in the bends and rebuilding them on the points, now forming islands by its deposits, and now removing them. Chief among the changes is the formation of cut-offs. Two eroding bends gradually approach each other until the water forces a passage across the narrow neck. As the channel distance between these bends may be many miles, a cascade perhaps 5 or 6 ft. in height is formed, and the torrent rushes through with a roar audible for miles. The checking of the current at the upper and lower mouths of the abandoned channel soon obstructs them by deposit, and forms in a few years one of the crescent lakes which are so marked a feature on the maps. At the mouth of the Red river, 316 m. above the passes, the water surface at the lowest stage is only 5½ ft. above the level of the Gulf, where the mean tidal oscillation is about 1½ ft. The river channel in this section is therefore a fresh-water lake. At the flood stage the surface rises 50 ft. at the mouth of Red river, but of course retains its level at the Gulf, thus giving the head necessary to force forward the increased volume of discharge. Above the mouth of the Red river the case is essentially different. The width increases and the depth decreases. Hence the general slope in long distances is here nearly the same at all stages. The effect of these different physical conditions appears in the comparative volumes which pass through the channel. At New Orleans the maximum discharge hardly reaches 1,200,000 cub. ft. per second, and a rising river at high stages carries only about 100,000 cub. ft. per second more than when falling at the same absolute level; but just below the mouth of the Ohio the maximum flood volume reaches 1,400,000 cub. ft. per second, and at some stages a rising river may carry one-third more water than when falling at the same absolute level. The river is usually lowest in October. It rises rapidly until checked by the freezing of the northern tributaries. It begins to rise again in February, as a consequence of the storms from the Gulf which traverse the basin of the Ohio, and attains its highest point about the 1st of April. It then falls a few feet, but the rains in the Upper Mississippi basin cause it to rise again and high water is maintained until some time in June by the late spring and early summer rains in the Missouri basin. As a rule the river is above mid-stage from January to August inclusive, and below that level for the remainder of the year.

Engineering Works.—Below Cape Girardeau there are at least 29,790 sq. m. of rich bottom lands which require protection from floods, and this has been accomplished to a great extent by the erection of levees. The first levee was begun in 1717, when the engineer, Le Blond de La Tour (d. about 1725) erected one a mile long to protect the infant city of New Orleans from overflow. Progress at first was slow. In 1770 the settlements extended only 30 m. above and 20 m. below New Orleans; but in 1828 the levees, although quite insufficient in dimensions, had become continuous nearly to the mouth of the Red river. In 1850 a great impulse was given to systematic embankment by the United States government, which turned over to the several states all unsold swamps and overflowed lands within their limits, to provide a fund for reclaiming the districts liable to inundation. The action resulting from this caused alarm in Louisiana. The aid of the government was invoked, and Congress immediately ordered the necessary investigations and surveys. This work was placed in charge of Captain (later General) Andrew A. Humphreys (1810–1883), and an elaborate report covering the results of ten years of investigation was published, just after the outbreak of the Civil War in 1861. In this report it was demonstrated that the great bottom lands above the Red river before the construction of their levees did not, as had been supposed, in Louisiana, serve as reservoirs to diminish the maximum wave in great flood seasons. Furthermore, the report argued that no diversion of tributaries was possible; that no reservoirs artificially constructed could keep back the spring freshets which caused the floods; that the making of cut-offs, which had sometimes been advocated as a measure of relief, was in the highest degree injurious; that outlets were impracticable from the lack of suitable sites; and, finally, that levees properly constructed and judiciously placed would afford protection to the entire alluvial region.

---

[1] Removed from office by Federal troops, 22nd of May 1865; W. L. Sharkey was appointed provisional governor by President Johnson.

[2] Removed from office by U.S. troops 15th of June 1868.

[3] Resigned 30th of November 1871.

[4] Resigned 29th of March 1876; succeeded by the president of the senate.

[5] The name is from the Algonkin *missi-sepe*, literally "father of waters."

During the Civil War (1861–65) the artificial embankments were neglected; but after its close large sums were expended by the states directly interested in repairing them. The work was done without concert upon defective plans, and a great flood early in 1874 inundated the country, causing terrible suffering and loss. Congress, then in session, passed an act creating a commission of five engineers to determine and report on the best system for the permanent reclamation of the entire alluvial region. Their report, rendered in 1875, endorsed the conclusions of that of 1861, and advocated a general levee system on each bank. This system comprised: (1) a main embankment raised to specified heights sufficient to restrain the floods; and (2) where reasonable security against caving required considerable areas near the river to be thrown out, exterior levees of such a height as to exclude ordinary high waters, but to allow free passage to great floods, which as a rule occur only at intervals of five or six years. An engineering organization was proposed for constructing and maintaining these levees, and a detailed topographical survey was recommended to determine their precise location. Congress promptly approved and ordered the survey; but strong opposition on constitutional grounds was raised to the construction of the levees by the government.

In the meantime complaints began to be heard respecting the low-water navigation of the river below the mouth of the Ohio. A board of five army engineers, appointed in 1878 to consider a plan of relief, reported that a depth of 10 ft. could probably be secured by narrowing the wide places to about 3500 ft. with hurdle work, brush ropes or brush dykes designed to cause a deposit of sediment, and by protecting caving banks by light and cheap mattresses. Experiments in these methods were soon begun and they proved to be effective.

The bars at the efflux of the passes at the mouth of the Mississippi were also serious impediments to commerce. The river naturally discharges through three principal branches, the south-west pass, the south pass and the north-east pass, the latter through two channels, the more northern of which is called Pass à l'Outre. In the natural condition the greatest depth did not exceed 12 or 13 ft. After appropriations by Congress in 1837, 1852 and 1856, a depth of 18 ft. was finally secured by dredging and scraping. The report of 1861 discussed the subject of bar formation at length, and the stirring up of the bottom by scrapers during the flood stages of the river (six months annually) was recommended by it. After the war this recommendation was carried into effect for several years, but experience showed that not much more than 18 ft. could be steadily maintained. This depth soon became insufficient, and in 1873 the subject was discussed by a board of army engineers, the majority approving a ship canal. In 1874 Congress constituted a special board which, after visiting Europe and examining similar works of improvement there, reported in favour of constructing jetties at the south pass, substantially upon the plan used by Pieter Caland (b. 1826) at the mouth of the Meuse; and in 1875 Captain James B. Eads (1820–1887) and his associates were authorized by Congress to open by contract a deep channel through the south pass upon the general plan proposed by this board. As modified in 1878 and 1879 the contract called for the maintenance for twenty years of a channel through the pass and over the bar not less than 26 ft. in depth throughout, a width of not less than 200 ft. and with a middle depth of 30 ft. The work was begun on the 2nd of June 1875. The required depth was obtained in 1879, and with few interruptions has been maintained. In 1902 Congress authorized preparations for the construction of a deeper (35 ft.) and a wider channel through the south-west pass; the work was begun in 1903 and virtually completed in 1909.

In the year in which Captain Eads opened the south pass of deep-water navigation Congress created a commission of seven members to mature plans for correcting and deepening the channel of the river, for protecting its banks and for preventing floods, and since then large expenditures for improvement between the head of the passes and the mouth of the Ohio have been under the control of this commission. In protecting the banks, mattresses of brush or small trees, woven like basket-work, were sunk on the portion of the bank at the time under water, by throwing rubble stone upon them, an excess of stone being used. A common size of mattress was 800 ft. long, counted along the bank, by 250 ft. wide. Sometimes a width of 300 ft. was used, and lengths have reached 2000 ft. The depth of water was often from 60 to 100 ft. At first these mats were light structures, but the loss of large quantities of bank protection by the caving of the bank behind them, or by scour at their channel edges, forced the commission steadily to increase the thickness and strength of the mattress, so that the cost of the linear foot of bank protection, measured along the bank, rose from $8 or $10 to $30 in the later work. The contraction works adopted were systems of spurs or pile dykes, running out from the shore nearly to the line of the proposed channel. Each dyke consisted of from one to four parallel rows of piles, the interval between rows being about 20 ft. and between piles in a row 8 or 10 ft. The piles and rows were strongly braced and tied together, and in many cases brush was woven into the upper row, forming a hurdle, in order further to diminish the velocity of the water below the spur. By 1893 it was evident that the cost, which had been estimated at $33,000,000 in 1881, would really be several times that amount, and that the works would require heavy expense for their maintenance and many years for their execution. Navigation interests demanded more speedy relief. The commission then began experimenting with hydraulic dredges, and in 1896 it adopted a project for maintaining a channel from the mouth of the Ohio to the passes that should be at least 9 ft. deep and 250 ft. wide throughout the year. Centrifugal pumps are used, the suction pipes being at the bow and the discharge at the stern through a line of pipes about 1000 ft. long, supported on pontoons. Water jets or cutters stir up the material to be dredged before it enters the suction pipes. The later dredges have a capacity of about 1000 cub. yds. of sand per hour, the velocity in the 32- to 34-in. discharge pipes being from 10 to 15 ft. per second. They cost from $86,000 to $120,000, and their working during a low-water season costs about $20,000. These dredges begin work on a bar where trouble is feared before the river reaches its lowest stage, and make a cut through it. A common cut is 2000 ft. long by 250 ft. wide, and 3 or 4 ft. deep. Since 1903 a channel of the proposed depth or more has been maintained.

In 1882 occurred one of the greatest floods known on the Mississippi, and extensive measurements of it were made. A maximum flood of 1,900,000 cub. ft. per second crossed the latitude of Cairo. Much of it escaped into the bottom lands, which are below the level of the great floods, and flowed through them to rejoin the river below. The flow in the river proper at Lake Providence, 542 m. below Cairo, was thus reduced to about 1,000,000 cub. ft. per second, while if the river had been confined by levees the flow between them would have been double, or about 2,000,000 cub. ft. per second. The volume of the levees in 1882 was about 33,000,000 cub. yds., and by the 30th of June 1908 had been increased to 219,621,594 cub. yds., of which the United States had built about one-half, and has expended on them $22,562,544. The length of the levees is about 1486 m., and they are continuous save where interrupted by tributaries or by high lands, from New Madrid, or 80 m. below Cairo, to Fort Jackson, 1039 m. below Cairo. The width of the interval between levees on the opposite banks of the river varies greatly; in many places the levees are built much nearer the normal margin of the river than is consistent with keeping the flood heights as low as possible. This has arisen from two causes: firstly, to give protection to lands already cultivated, which lie usually near the bank of the river; secondly, to avoid the lower ground, which, owing to the peculiar formation, is found as one goes back from the river. Another bad result of this nearness of the levees to the bank of the river is the loss of levees by caving, which was nearly 5,000,000 cub. yds. in 1904–1905, and can only be prevented by bank protection, costing $150,000 per mile, to protect a levee perhaps 16 ft. high costing about $30,000 per mile. The levees have top widths of 8 ft., side slopes of one-third, and banquettes when their heights exceed about 10 ft. The grades of the levees are usually 3 ft. above the highest water, and have to be raised from year to year as greater confinement of water gives greater flood heights. When this system is completed there will probably be hundreds of miles of levee with heights exceeding 14 ft. In 1899, after about $28,000,000 had been spent on levees by the United States and by the local authorities, the commission submitted an estimate for additional work on levees, amounting to 124,000,000 cub. yds. and costing $22,000,000. The effect of the levees has been to increase flood heights. Though the

Mississippi River Commission was forbidden by Congress to build levees to protect lands from overflow, a majority of its members believed them useful for the purpose of navigation improvement. They have, however, effected no sensible improvement in the navigation of the river at low stages, and at other stages no improvement was needed for the purposes of navigation. Neither did they prevent a destructive flood in 1897 and again in 1903. By the 30th of June 1908, $57,510,216.81 had been appropriated for the commission's work below the mouth of the Ohio.

From the mouth of the Ohio to the mouth of the Missouri, a distance of about 210 m., the river is affected by back water from the Ohio which increases the deposit of sediment, and although the banks increase in height above Cape Girardeau the channel was in its natural state frequently a mile or more in width, divided by islands, and obstructed by bars on which the low-water depth was only 3½ to 4 ft. The improvement was begun in 1872, and in 1881 a project was adopted for narrowing the channel to approximately 2500 ft. In 1896 dredging was begun and in 1905 the further execution of the original project of 1881 was discontinued, because of a new plan for a channel 14 ft. deep from the Great Lakes to the Gulf.

The Upper Mississippi carries only a small amount of sediment and was navigable in its natural state to St Paul, although at low water the larger river boats could ascend no farther than La Crosse, Wisconsin. In 1879 Congress adopted a project for obtaining a channel with a minimum depth at low water of 4½ ft., chiefly by means of contraction works. In 1907 Congress authorized further contraction, dredging, the construction of a lateral canal at Rock Island Rapids, and the enlargement of that at Des Moines Rapids with a view to obtaining a channel nowhere less than 6 ft. in depth at low water. By means of two locks and dams, which were begun in 1894 and were about three-fourths complete in 1908, a navigable channel of the same depth will be extended from St Paul to Minneapolis. The United States government has constructed dams at the outlets of lakes Winnibigashish, Cass, Leech, Pine, Sandy and Pokegama, and thereby created reservoirs having a total storage capacity of about 95,000,000,000 cub. ft. This reservoir system, which may be much enlarged, is also beneficial in that it mitigates floods and regulates the flow for manufacturing purposes and for logging.

Although the United States government has expended more than $70,000,000 on the Mississippi river between the mouth of the Missouri and the head of the passes, the improvement of navigation thereon has not been great enough to make it possible for river freighters to force down railway rates by competition. But it is no longer merely a question of competition. The productivity of this region has become so enormous that railways alone cannot meet the requirements of its commerce, and a persistent demand has arisen for a channel 14 ft. deep from the Great Lakes to the Gulf. The first great impetus to this demand was given in 1900, when a canal 24 ft. in depth, and known as the Chicago Drainage Canal, was opened from the Chicago river to Lockport, Illinois, on the Des Plaines river, 34 m. from Lake Michigan. Two years later Congress appropriated $200,000 for the Mississippi River Commission to make a survey and prepare plans, with estimates of cost, for a navigable waterway 14 ft. in depth from Lockport to St Louis. The commission reported favourably in 1905, and in 1907 Congress provided for another commission, which in June 1909 reported against the 14 ft. channel, estimating that it would cost $128,000,000 for construction and $6,000,000 annually for maintenance, and considered a 9-ft. channel (8 ft. between Ohio and St Louis) sufficient for commercial purposes.

The Ohio is commercially the most important tributary, and in flood time most of the commerce on the Lower Mississippi consists of coal and other heavy freight received from the mouth of this river. Its navigation at low water has also been improved by dredging, rock excavation and contraction works. In its upper reaches a channel 9 ft. in depth had been obtained before 1909 by the construction of a number of locks with collapsible dams which are thrown down by a flood. It is the plan of the government to extend this system to the mouth of the river, and it has been estimated that a channel 12 to 14 ft. in depth may ultimately be obtained by a system of mountain reservoirs. Furthermore, the government has given to a corporation a franchise for the connexion of the Ohio at Pittsburg with Lake Erie near Ashtabula, Ohio, by means of a canal 12 ft. in depth. The Missouri is navigable from its mouth to Fort Benton, a distance of 2285 m., and it had become a very important highway of commerce when the first railway, the Hannibal & St Joseph, reached it in 1859. Its commerce then rapidly disappeared, but regular navigation between Kansas City and St Louis was re-established in 1907 and a demand has arisen for a 12-ft. channel from the mouth of the river to Sioux City, Iowa. The Red, Arkansas, White, Tennessee, and Cumberland rivers, which are parts of the Mississippi system, have each a navigable mileage exceeding 600 m.

History.—Although the Mississippi river was discovered in its lower course by Hernando de Soto in 1541, and possibly by Alonso Alvarez de Pineda in 1519, Europeans were not yet prepared to use the discovery, and two Frenchmen, Louis Joliet and Father Jacques Marquette, first made it generally known to the civilized world by a voyage down the river from the mouth of the Wisconsin to the mouth of the Arkansas in 1673.[1] In 1680 Louis Hennepin, sent by La Salle, who planned to acquire for France the entire basin drained by the great river and its tributaries, explored the river from the mouth of the Illinois to the Falls of St Anthony, where the city of Minneapolis now stands, and two years later La Salle himself descended from the mouth of the Illinois to the Gulf, named the basin "Louisiana," and took formal possession of it in the name of his king, Louis XIV. By the war which terminated (1763) in the Treaty of Paris, Great Britain wrested from France all that part of the basin lying east of the middle of the river (except the island of New Orleans at its mouth), together with equal rights of navigation; and the remainder of the basin France had secretly ceded to Spain in 1762. During the War of Independence the right to navigate the river became a troublesome question. In 1779 the Continental Congress sent John Jay to Spain to negotiate a treaty of commerce, and to insist on the free navigation of the Mississippi, but the Spanish government refused to entertain such a proposition, and new instructions that he might forego that right south of 31° N. latitude reached him too late. While the commissioners from Great Britain and the United States were negotiating a treaty of peace at Paris, Spain, apparently supported by France, sought to prevent the extension of the western boundary of the United States to the Mississippi, but was unsuccessful, and the United States acquired title in 1783 to all that portion of the basin east of the middle of the river and north of 31° N. lat. In 1785 Congress appointed John Jay to negotiate a commercial treaty with Don Diego de Gardoqui, the Spanish minister to the United States, but the negotiations resulted in nothing. For the next ten years the Spaniards imposed heavy burdens on the American commerce down the Mississippi, but in 1794 James Monroe, the United States minister to France, procured the aid of the French government in further negotiations, for which Thomas Pinckney had been appointed envoy extraordinary, and in 1795 Pinckney negotiated a treaty which granted to the United States the free navigation of the river from its source to the Gulf and the privilege of depositing American merchandise at the port of New Orleans or at some other convenient place on the banks. Spain retroceded Louisiana to France in 1800, but the Louisiana Purchase in 1803 left very little of the Mississippi basin outside of the United States.

As the headwaters of the river were not definitely known, the United States government sent Zebulon M. Pike in 1805 to explore the region, and on reaching Leech Lake, in February 1806, he pronounced that the main source. In 1820 Lewis Cass, governor of Michigan territory, which then had the Mississippi for its western boundary, conducted an expedition into the same region as far as Cass Lake, where the Indians told him that the true source was about 50 m. to the W.N.W., but as the water was too low to proceed by canoe he returned, and it remained for Henry Schoolcraft, twelve years later, to discover Lake Itasca, which occupies a low depression near the centre of the basin in which the river takes its rise. Jean N. Nicollet, while in the service of the United States government, visited Lake Itasca in 1836, and traced its principal affluent, since known as Nicollet's Infant Mississippi river, a few miles S.S.W. from the lake's western arm. Jacob Vradenberg Brower (1844–1905), who was commissioned by the Minnesota Historical Society in 1889 to make a more detailed survey, traced the source from Nicollet's Infant Mississippi to the greater ultimate reservoir, which contains several lakelets, and lies beyond Lake Itasca, 2553 m. by water from the Gulf of Mexico, and 1558 ft. above the sea. Soon after this survey the state of Minnesota created Itasca State Park, which contains both Itasca Lake and its affluents from the south.

---

[1] It seems probable that Joliet and Marquette were preceded by two other Frenchmen, Pierre Esprit Radisson and Menard Chouart des Groseilliers, who apparently reached the Upper Mississippi in or about 1665; but their claim to priority has been the subject of considerable controversy, and, at all events, there was no general knowledge of the river until after the voyage of Joliet and Marquette.

From the close of the 17th century until the building of the first railways in the Mississippi basin, in the middle of the 19th century, the waterways of the Mississippi system afforded practically the only means of communication in this region. During the early years of the French occupancy trade with the Indians was the only important industry, and this was carried on almost wholly with birch canoes and a few pirogues; but by 1720 immigrants were coming in considerable numbers both by way of the Great Lakes and the mouth of the Mississippi, and to meet the demands of a rapidly expanding commerce barges and keelboats were introduced. The development of the Mississippi Valley must have been slow until the railways came had it not been for the timely application of the power of steam to overcome the strong current of the Lower Mississippi. Even without the steamboat, however, the Mississippi was indispensable to the early settlers, and the delay of the United States in securing for them its free navigation resulted in threats of separation from the Union. The most formidable movement of this kind was that of 1787–1788, in which James Wilkinson, who had been an officer in the War of Independence, plotted for a union with Spain. Steamboat navigation on this river system was begun in 1811, when the "New Orleans," which had been built by Nicholas Roosevelt (1767–1854), made the trip from Pittsburg to New Orleans, but it was six years later before the steamboat was sufficiently improved to ascend to St Louis. In 1817 the commerce from New Orleans to the Falls of the Ohio, at Louisville, was carried in barges and keel-boats having a capacity of 60 to 80 tons each, and 3 to 4 months were required to make a trip. In 1820 steamboats were making the same trip in 15 to 20 days, by 1838 in 6 days or less; and in 1834 there were 230 steamboats, having an aggregate tonnage of 39,000 tons, engaged in trade on the Mississippi. Large numbers of flat boats, especially from the Ohio and its tributaries, continued to carry produce down stream; an extensive canal system in the state of Ohio, completed in 1842, connected the Mississippi with the Great Lakes; these were connected with the Hudson river and the Atlantic Ocean by the Erie Canal, which had been open since 1825. Before the steamboat was successfully employed on the Mississippi the population of the valley did not reach 2,000,000, but the population increased from approximately 2,500,000 in 1820 to more than 6,000,000 in 1840, and to 14,000,000 or more in 1860. The well-equipped passenger boats of the period immediately preceding the Civil War were also a notable feature on the Ohio and the Lower Mississippi.

In the Civil War the Lower Mississippi, the Ohio, and its two largest tributaries—the Cumberland and the Tennessee—being still the most important lines of communication west of the Appalachian Mountains, determined largely the movements of armies. The adherence of Kentucky to the Union excluded the Confederacy from the Ohio, but especially disastrous was the fall of Vicksburg and Port Hudson, whereby the Confederacy was cut in two and the entire Mississippi became a Federal highway. Under Federal control it was closed to commerce, and when the war was over the prosperity of the South was temporarily gone and hundreds of steamboats had been destroyed. Moreover, much of the commerce of the West had been turned from New Orleans, via the Mississippi, to the Atlantic seaboard, via the Great Lakes and by new lines of railways, the number of which rapidly increased. There was, of course, some revival of the Mississippi commerce immediately after the war, but this was checked by the bar at the mouth of the south-west pass. Relief was obtained through the Eads jetties at the mouth of the south pass in 1879, but the facilities for the transfer of freight were far inferior to those employed by the railways, and the steamboat companies did not prosper. But at the beginning of the 20th century the prospects of communication with the western coast of North America and South America, and with the Orient by way of an isthmian canal, the inadequate means of transportation afforded by the railways, the efficiency of competing waterways in regulating freight rates, and the consideration of the magnificent system of inland waterways which the Mississippi and its tributaries would afford when fully developed, have created the strong demand for river improvement.

MISSOLONGHI, or Mesolonghi (*Μεσολόγγιον*), the chief town of the monarchy of Acarnania and Aetolia, Greece. It is on the N. side of the Gulf of Patras, about 7 m. from the coast; pop., about 8300. The place is notable for the siege which Mavrocordato and Botzaris sustained in 1822 and 1823 against a Turkish army 11,000 strong, and for the more famous defence of 1825–26. Byron died here in 1824, and is commemorated by a cenotaph and a statue.

MISSOULA, a city and the county-seat of Missoula county, Montana, U.S.A., on the Clark Fork of the Columbia (here called the Missoula river), about 125 m. W.N.W. of Helena. Pop. (1900), 4366 (1020 foreign-born); (1910), 12,869. It is served by the Chicago, Milwaukee & Puget Sound railway, and by the Northern Pacific railway, which has shops here and of which Missoula is a division headquarters. There is an electric railway from Missoula to Hamilton, about 48 m. south. The Northern Pacific railway maintains a large hospital here, and St Patrick's hospital is maintained by sisters of charity. Missoula is about 3200 ft. above sea-level, with Mount Jumbo immediately north, and University Mountain immediately south of the Clark Fork, and the Bitter Root range to the west. The city is situated on the bed of a prehistoric lake. Missoula is the seat of the Sacred Heart academy (for girls), of a Christian Brothers' school (for boys), of the Garden City commercial college, and of the state university (founded in 1893, and opened in 1895), which occupies a campus of 40 acres. On the Bitter Root river, 4 m. distant, is the United States army post, Fort Missoula. Missoula has considerable trade with the surrounding country in farming, fruit-growing, lumbering and mining. The Clark Fork furnishes water power, and at Bonner, 6 m. east, is the Clark dam (28 ft.), which furnishes electric power. Missoula was founded in 1864, and chartered as a city in 1887.

MISSOURI, a north-central state of the United States of America, and one of the greatest and richest, and economically one of the most nearly independent, in the Union, lying almost midway between the two oceans, the Gulf of Mexico and Canada. It is bounded N. by Iowa; E. by Illinois, Kentucky and Tennessee; S. by Arkansas; and W. by Oklahoma, Kansas and Nebraska. Its N. and S. limits are mainly coincident with the parallels of 40° 35′ and 36° 30′ N. lat.—the southernmost boundary, in the S.E. corner, is the meridian of 36° N. lat.—and much of the western border is the meridian of 94° 43′ W. long. respectively; but natural boundaries are afforded on the extreme N.E. by the Des Moines river, on the E. by the Mississippi, on the S.E. by the St Francis and on the N.W. by the

Missouri. Altogether, about 850 m., or considerably more than half of the entire boundary, is water-front: about 560 m. along the Mississippi, about 208 m. along the Missouri, and about 100 m. along the St Francis and Des Moines. The length of the state from north to south, disregarding the St Francis projection southward, is 282 m.,[1] the width from west to east varies from 208 to 308 m., and the total area is 69,420 sq. m., of which 693 sq. m. are water surface.

Physical Features.—Missouri has three distinct physiographic divisions: a north-western upland plain, or prairie region; a lowland, in the extreme south-east; and, between these, the Missouri portion of the Ozark uplift. The boundary between the prairie and Ozark regions follows the Missouri river from its mouth to Glasgow, running thence south-westward, with irregular limits, but with a direct trend, to Jasper county at the south-east corner of Kansas; and the boundary between the Ozark and embayment regions runs due south-west from Cape Girardeau.

1. The prairie region embraces, accordingly, somewhat more than "northern" Missouri—*i.e.* the portion of the state north of the Missouri river—and somewhat more than a third of the state. It is a beautiful, rolling country, with a great abundance of streams; more hilly and broken in its western than in its eastern half. The elevation in the extreme north-west is about 1200 ft. and in the extreme north-east about 500 ft., while the rim of the region to the south-east, along the border of the Ozark region, has an elevation of about 900 ft. The larger streams have valleys 250 to 300 ft. deep and sometimes 8 to 10 m. broad, the country bordering them being the most broken of the region. The smaller streams have so eroded the whole face of the country that little of the original surface plain is to be seen. The Mississippi river is skirted throughout the length of the state by contours of 400 to 600 ft. elevation.

2. The Ozark region is substantially a low dome, with local faulting and minor undulations, dominated by a ridge—or, more exactly, a relatively even belt of highland—that runs from near the Mississippi about Ste Genevieve county to Barry county on the Arkansas border; the contour levels falling with decided regularity in all directions below this crest. High rocky bluffs that rise precipitously on the Mississippi, sometimes to a height of 150 ft. or so above the water, from the mouth of the Meramec to Ste Genevieve, mark where that river cuts the Ozark ridge, which, across the river, is continued by the Shawnee Hills in Illinois. The elevations of the crest in Missouri (the highest portion of the uplift is in Arkansas) vary from 1100 to 1600 ft. This second physiographic region comprehends somewhat less than two-thirds of the area of the state. The Burlington escarpment, which in places is as much as 250 to 300 ft. in height, runs along the western edge of the Cambro-Ordovician formations and divides the region into an eastern and a western area, known respectively to physiographers as the Salem Upland and the Springfield Upland.[2] Superficially, each is a simple rolling plateau, much broken by erosion (though considerable undissected areas drained by underground channels remain), especially in the east, and dotted with hills; some of these are residual outliers of the eroded Mississippian limestones to the west, and others are the summits of an archaean topography above which sedimentary formations that now constitute the valley-floor about them were deposited and then eroded. There is no arrangement in chains, but only scattered rounded peaks and short ridges, with winding valleys about them. The highest points in the state are Tom Sauk Mountain (more than 1800 ft.), in Iron county and Cedar Gap Plateau (1683 ft.), in Wright county. Few localities have an elevation exceeding 1400 ft. Rather broad, smooth valleys, well degraded hills with rounded summits, and—despite the escarpments—generally smooth contours and sky-lines, characterize the whole of this Ozark region.

3. The third region, the lowlands of the south-east, has an area of some 3000 sq. m. It is an undulating country, for the most part well drained, but swampy in its lowest portions. The Mississippi is skirted with lagoons, lakes and morasses from Ste Genevieve to the Arkansas border, and in places is confined by levees.

The drainage of the state is wholly into the Mississippi, directly or indirectly, and almost wholly into either that river or the Missouri within the borders of the state. The latter stream, crossing the state and cutting the eastern and western borders at or near St Louis and Kansas City respectively, has a length between these of 430 m. The areas drained into the Mississippi outside the state through the St Francis, White and other minor streams are relatively small. The larger streams of the Ozark dome are of decided interest to the physiographer. Those of the White system have open-trough valleys bordered by hills in their upper courses and canyons in their lower courses; others, notably the Gasconade, exhibit remarkable differences in the drainage areas of their two sides, with interesting illustrations of shifting water-partings; and the White, Gasconade, Osage and other rivers are remarkable for upland meanders, lying, not on flood-plains, but around the spurs of a highland country.[3]

Caves, chiefly of limestone formation, occur in great numbers in and near the Ozark Mountain region in the south-western part of Missouri. More than a hundred have been discovered in Stone county alone, and there are many in Christian, Greene and McDonald counties. The most remarkable is Marble Cave, a short distance south-east of the centre of Stone county. The entrance is through a large sink-hole at the top of Roark Mountain, from which there is a passage-way to an open chamber. This extraordinary hall-like room is about 350 ft. long and about 125 ft. wide, has bluish-grey limestone walls, and an almost perfectly vaulted roof, rising from 100 to 195 ft. Its acoustic properties are said to be almost perfect, and it has been named "the Auditorium." At one end is a remarkable stalagmitic formation of white and gold onyx, about 65 ft. in height and about 200 ft. in girth, called "the White Throne." Jacob's Cavern (*q.v.*), near Pineville, McDonald county, disclosed on exploration skeletons of men and animals, rude implements, &c. Crystal Cave, near Joplin, Jasper county, has its entire surface lined with calcite crystals and scalenohedron formations, from 1 ft. to 2 ft. in length. Knox Cave, in Greene county, and several caverns near Ozark, in Christian county, are also of interest. Other caves include Fried's Cave, about 6 m. north-east of Rolla, Phelps county, Hannibal Cave (in Ralls county, about 1 m. south of Hannibal), which has a deep pool containing many eyeless fish; and various caverns in Miller, Ozark, Greene and Parry counties.

Geology.—The geological history of the state covers the period from Algonkian to late Carboniferous time, after which there is a gap in the record until Tertiary time, except that there was apparently a temporary depression of the north-western and south-western corners in the Cretaceous age. Northern Missouri is covered with a mantle of glacial deposits, generally thick, although in the stream valleys of the north-east the bed-rocks are widely exposed. The southern limit of these glacial deposits is practically the bluffs bordering the Missouri river, except for a narrow strip along the Mississippi below St Louis. These Pleistocene deposits include bouldery drift, loess, terrace deposits and alluvium. The till is generally less than 5 ft. and rarely more than 40 ft. deep, but in some localities it reaches a thickness of 200 ft., or even more. Modified drift and erratics were also widely deposited. The loess, however—reddish-brown, buff or grey in colour, according to the varying proportions of iron oxide—is almost everywhere spread above the drift. It is exposed in very deep cuts along the bluffs of the Missouri. Southern Missouri is covered, generally speaking, with residuary rocks. The embayment region is of Tertiary origin, containing deposits of both neocene and eocene periods. Regarding now the outcrops of bed-rock, there are exposures of Algonkian (doubtful, and at most a mere patch on Pilot Knob), Archean, Cambrian, Ordovician, Silurian, Devonian, sub-Carboniferous and Carboniferous. The St François Mountains and the neighbouring portion of the Ozark region are capped with Archean rocks. All the rest of the Ozark region except the extreme south-western corner of the state is Cambro-Ordovician. Along the margin of this great deposit, on the Mississippi river below St Louis and along the northern shore of the Missouri near its mouth, is an outcrop of Silurian. Parallel to this in the latter locality, and lying also along the Mississippi near by to the north, as well as in the intervening country between the two rivers, are strips of Devonian. Both this and the Silurian are mere fringes on the great area of Cambro-Ordovician. Next, covering the north-eastern and south-western corners of the state, and connecting them with a narrow belt, are the lower Carboniferous measures (which also appear in a very narrow band along the Mississippi for some distance below St Louis). The western edge of these follows an irregular line from Schuyler county, on the northern border, to Barton county, on the western border, of the state, but with a great eastward projection north of the Missouri river, to Montgomery county. This line defines the eastern limit of the Coal Measures proper, which cover a belt 20 to 80 m. in width. Finally, to the west of these, and covering the north-western corner of the state, are the upper coal-measures. Thus the state is to be conceived, in geological history, as gradually built up around an Archean island in successive seas, the whole of the state becoming dry land after the post-Carboniferous uplift. Until the post-Mesozoic uplift of the Rocky Mountain region the north-western portion of the state drained westward.

Fauna.—Excepting the embayment region, Missouri lies wholly within the Carolinian area of the Upper Austral life-zone; the

---

[1] Counting the St Francis projection the length is 328 m.

[2] Both the Ozark region and the prairie region are divided by minor escarpments into ten or twelve sub-regions.

[3] There has been some controversy as to whether this condition is due to the elevation and corrosion of original flood-plain meanders after their development in a past base-level condition—which theory is probably correct—or to the natural, simultaneous lateral and vertical cut of an originally slightly sinuous stream, under such special conditions of stream declivity and horizontal bed-strata (conditions supposed by some to be peculiarly fulfilled in this region) as would be favourable to the requisite balance of bank cutting and channel incision.

embayment lies in the Austro-riparian area of the same zone. Among wild animals, deer and bear are not uncommon. Opossums, raccoons, woodchucks, foxes, grey squirrels and fox-squirrels are common. The game birds include quail ("Bob White") and partridges. Prairie chickens (pinnated grouse), pheasants and wild turkeys, all very common as late as 1880, are no longer to be found save in remote and thinly-settled districts. A state fish commission has laboured to increase the common varieties of river fish. So far as these are an article of general commerce, they come, like frogs, terrapin and turtles, mainly from the counties of the embayment region. Mussel fisheries, an industry confined to the Mississippi river counties from Lincoln to Lewis, are economically important, as the shells are used in the manufacture of pearl buttons. There are state fish-hatcheries at St Louis and St Joseph.

Flora.—The most valuable forests are in the southern half of the state, which, except where cleared for farms, is almost continuously wooded. An almost entire absence of underbrush is characteristic of Missouri forests. The finest woods are on the eastern upland and on the Mississippi lowlands. The entire woodland area of the state was estimated at 41,000 sq. m. by the national census of 1900. Ash, oaks, black and sweet gums, chestnuts, hickories, hard maple, beech, walnut and short-leaf pine are noteworthy among the trees of the Carolinian area; the tupelo and bald cypress of the embayment region, and long-leaf and loblolly pines, pecans and live oaks of the uplands, among those characteristic of the Austro-riparian. But the habitats overlap, and persimmons and magnolias of different species are common and notable in both areas. The heavy timber in the south-eastern counties (cypress, &c.), and even scattered stands of such valuable woods as walnut, white oak and red-gum, have already been considerably exploited.

Climate.—Missouri has a continental climate, with wide range of moisture and temperature. The Ozark uplift tempers very agreeably the summers in the south, but does not affect the climate of the state as a whole. The normal mean annual temperature for the entire state is about 54° F.; the normal monthly means through the year are approximately 29·6, 30·3, 42, 55·4, 64·6, 73·2, 77·1, 75·7, 68·2, 57, 42·8 and 33·1° F. The south-eastern corner is crossed by an annual isotherm of 60°, the north-western by one of 50°; and although in the former region sometimes not a day in the year may show an average temperature below freezing-point, at Jefferson City there are occasionally two months of freezing weather, and at Rockport three. Nevertheless, the yearly means of the five districts into which the state is divided by the national weather service exhibit very slight differences: approximately 52·1, 52·7, 54·4, 56·1 and 55·7° F. respectively for the north-west, north-east, central, south-east and south-west. On the other hand, the range in any month of local absolute temperatures over the state is habitually great (normally about 50° in the hottest and 100° or more in the coldest months), and likewise the annual range for individual localities (90° to 140°). Temperatures as high as 100° to 105° and as low as −20° or −30° are recorded locally almost every year, and the maximum range of extremes shown by the records is from 116° at Marble Hill, Bollinger county, in July 1901, to −40° at Warsaw, Benton county, in February 1905. The average fall of snow, which is mostly within the months from November to March inclusive, ranges from about 8 in. in the south-east counties to 30 in. in the north-west counties. The Missouri river is often closed by ice, and the Mississippi at St Louis, partly because it is obstructed by bridges, sometimes freezes over so that for weeks together horses and wagons can cross on the ice.

The average yearly rainfall for the state as a whole is about 39 in., ranging from 53·7 in. in 1898 to 25·3 in. in 1901. The prevailing winds are southerly, although west winds are common in winter. Winds from the north and west are generally dry, cool, clear and invigorating; winds from the south and east warm, moist and depressing. Rainfall comes from the Gulf of Mexico. The south-east winds blow from the arid lands and carry rising temperatures across the state; and the winter anti-cyclones from the north-west carry low temperatures even to the southern border. Missouri lies very frequently in the dangerous quadrant of the great cyclonic storms passing over the Mississippi valley—indeed, northern Missouri lies in the area of maximum frequency of tornadoes.

Agriculture.—Few states have so great a variety of soils. This variety is due to the presence of different forms of glacial drift, and to the variety of surface rocks. The northern half of the state is well watered and extremely fertile. The south-eastern embayment is rich to an exceptional degree. Speaking generally, the Ozark region is characterized by reddish clays, mixed with gravels and stones, and cultivable in inverse proportion to the amount of these elements; northern Missouri by a generally black clay loam over a clay subsoil, with practically no admixture of stones; the southern prairies, above referred to, share the characteristics of those north of the Missouri. The Mississippi embayment is in parts predominantly sandy, in others clayey; it is mainly under timber. The state as a whole is devoted predominantly to agriculture. Within its borders or close about them are the centres of total and of improved farm acreage, of total farm values, of gross farm income, of the growth of Indian corn, of wheat, and of oats. In 1900 agriculture absorbed the labour of 41·3% of the total working population of the state. Of the area of the state 77·3% was included in that year in farm land (33,997,873 acres); and of this, 67·4% was improved. The average size of a farm was 119·3 acres; 39·9% of all farm families owned a home clear of all incumbrance; and the percentages of farms operated by owners, cash tenants and share tenants were respectively 69·5, 11·0 and 19·5. Negroes worked 1·7% of the total acreage. The total value of farm-property was $1,033,121,897. The aggregate values of farm products in 1899 was $219,296,970, and this total consisted of $117,012,895 in crops (area in crops, 14,827,620 acres), $97,841,944 in animal products, and $4,442,131 of forest by-products of farm operations. Indian corn is the most prominent single crop; in 1899 it was valued at $61,246,305. Of other cereals none except wheat is produced in any quantity as compared with other states. Tobacco is grown over half the area of the state, but especially in the central and north-central counties, and cotton along the Arkansas border counties, but especially in the embayment lowlands. Orchard fruits, small fruits and grapes are produced in large quantities, and a fruit experiment station, the only institution of its kind in the country in 1900, is maintained by the state at Mountain Grove, in Wright county. To a slight extent it is possible to grow fruit of distinctively southern habitat, but even pears (a prominent and valuable crop) are uncertain in returns. Apples are grown to best advantage in the north-west quarter; peaches on the Arkansas border; pears along the Mississippi; melons in the sandy regions of the embayment; small fruits in the south-west. Grapes are mainly grown in the Ozark region, and wine is produced in Gasconade and other central and north-central counties in amounts sufficient to place Missouri, California aside, in the front rank of wine states in the Union. Indian corn and abundant grasses give to Missouri, as to the other central prairie states, a sound basis for her live-stock interests. In 1900 the value of her live stock was $160,540,004. Two of the four remount purchasing stations of the United States Army are at St Louis and Kansas City. As a mule market Missouri has no rival. Sheep are herded in the southern Ozarks.

Minerals.—Coal, lead, zinc, clays, building stones and iron are the most important minerals. Cobalt and nickel are associated with lead in the St François field; but though the American ouput is almost exclusively derived from Missouri the production is small in comparison with the amount derived from abroad. Practically the whole comes from Mine La Motte, in Madison county. Missouri is also the largest producer in the Union of tripoli and of barytes. Copper occurs in various localities, but is of economic importance only in the Ozark uplift; it was first mined in small quantities in 1837. The value of the copper mined in 1906 (based on smelter returns) was $54,347. Mineral waters—muriatic, alkaline chalybeate and sulphuric—occur widely. Various mineral paint bases (apart from lead, zinc, baryta and kaolin) are produced in small quantities. Iron, once an extremely important product, has ceased since about 1880 to be significant in the general production of the country. But it is of great importance to the state, nevertheless, and its production has possibilities much beyond present realization. The ore occurs in two forms, haematites and limonites; the specular hematites often being grouped, for practical purposes, into two classes—those occurring in porphyry and those occurring in sandstone. The haematites are found not only in the archean porphyries but in Cambrian limestone and sandstone, and in the sub-Carboniferous formations; while the limonites are confined almost exclusively to the Cambrian. The bedded haematites and limonites have been little exploited. Mining was begun in Iron and Crawford counties in the second decade of the 19th century; at Iron Mountain in 1846, and at Pilot Knob in the next year. Since 1880 the output of the state has been falling, and the total production up to 1902 did not exceed 9,000,000 tons of ore; in 1906 the output was 80,910 tons. Iron pyrites, which occurs widely and abundantly, has become of value as material for the preparation of sulphuric acid.

The limits of the coal belt have already been defined. The area of the Coal Measures is about 23,000 sq. m., and that of those classed by the National Geological Survey as probably productive is about 14,000 sq. m., or nearly the entire area of the lower measures. The coal is almost wholly bituminous, with very little cannelite. The seams are generally from one to five feet in thickness. Macon, Lafayette and Adair are the leading counties in output; Lexington and Bevier are the leading mining centres. The total output from 1840 to 1902 was about 78,500,000 short tons; the annual output first passed 1,000,000 tons in 1876, and 2,000,000 tons in 1882; and from 1901 to 1905 the yearly output, steadily increasing, averaged 4,196,688 tons, of a value at the mines of $6,266,154; the output in 1908 was 3,317,315 tons, with a spot value of $5,444,907. Superficial evidences of natural gas and petroleum are abundant in western and north-western Missouri, but these have not been found in commercially profitable quantities. The total value of natural gas from wells in Missouri in 1908 was $22,592. A few small oil wells are open near the Kansas line. Both crude oil and natural gas are drawn from Kansas for the supply of Kansas City and other parts of western Missouri.

Lead occurs in three areas in southern Missouri. In the first, of which St François county is the centre, it occurs generally alone disseminated in Cambrian limestone; in the second, of which the counties immediately south-west of Jefferson City are the centre, it occurs with zinc in reticulated deposits and fissure veins in clays and clastic limestones; and in the third, of which Jasper county is much the most important county, the two metals occur in pockets and joints in the Burlington-Keokuk beds of the sub-Carboniferous. The first is the great lead area, the third the great zinc area; the second is no longer of relative importance. The lead ores are galena and carbonate; the zinc ores, calamine, smithsonite and blende. The mines in the St François field were worked by the French from early in the 18th century. The oldest, Mine La Motte (Madison county), discovered in 1715 by De la Motte Cadillac, is still a heavy producer. St François county alone produces about nine-tenths the yield of the field; Madison, Washington, Jefferson and Franklin counties furnish most of the remainder. Large quantities of lead are also obtained from the zinc field of the south-west. Both the St François and Jasper ores yield from 70 to 75% of metal in final product, and assay even higher. It has been estimated that down to 1893 1,100,000 tons of ore, yielding metal worth $74,000,000, had been taken from the state, fully half of this having been mined in the preceding twenty years. The total output for the state in 1908 was 114,459 tons, valued at $12,134,556; of this 116,531 tons came from the central and south-east field, and of the remainder 15,240 tons from the Webb City—Prosperity camp. Zinc was originally a hindering by-product of lead mining in the south-west, and was thrown away; but it long ago became the chief product in value in this field. The so-called "Joplin district" of south-western Missouri and south-eastern Kansas—three-fourths of it being in Missouri—produces nine-tenths of all the zinc mined in the United States. Mining in south-western Missouri began about 1851, but zinc was of no importance in the output until 1872. In the next thirty-one years the aggregate product was about 3,000,000 tons of ore, worth some $100,000,000. The output from 1894 to 1905 averaged 219,874 tons of ore yearly; in 1908 it was 107,404 tons. The history of the St François, Granby and Joplin districts has been sensational. The fortunes of the last have largely revolutionized the conditions and prospects of the south-western counties. Silver is found in connexion with lead and zinc mining; in 1908 the total output was 49,131 oz., valued at $26,039. Clays occur in amounts and varieties surpassed by the deposits in very few if any states of the Union. They are in every form from the rare to the common—glass pot clay, ball clays, kaolins, flint fireclays, plastic fireclays, stone-ware clays, paving-brick shales, building-brick and gumbo clays. Plastic fireclays, paving and brick clays are available in seemingly limitless quantities. The loess, the re-sorted residual clays, and the glacial clays are all used for the production of brick. Clays occur, in short, all over the state; and their use is almost as general. In 1905 and 1907 the rank of Missouri was sixth in the Union in the value of clay products—namely, $6,203,411 in 1905 and $6,898,871 in 1907. There has been no more than the slightest beginning made in the utilization of these resources. Stone resources are also large. Limestones are by far the most important; red and gray granites, sandstones and marble (Ste Genevieve county) being of little more than local importance. In 1908 the total value of stone quarried was $2,306,058. Tripoli is quarried particularly in Newton county, where it has been produced since 1872, and though not produced in great quantities has value from its general scarcity. This Missouri tripoli is a finely decomposed light rock, about 98% silica, and is used for filter stones and as an abrasive. "Chat"—finely crushed flint and limestone yielded as tailings in the lead and zinc mines—finds many uses. Limestone is quarried all over the state (except in the embayment region). There are unlimited supplies of clay, shale and limestone, the three essential constituents of Portland cement, and the manufacture of this, begun in 1902, at once assumed important proportions. Quicklime manufacture is also an important industry. In 1908 the product of quicklime was 167,060 tons.

Manufactures.—Manufacturing and mechanical pursuits absorbed in 1900 the labours of 19·5% of all persons engaged in gainful occupations, less than half as many as were engaged in agriculture. Though an agricultural state, Missouri had in 1900 three cities with populations of above 100,000, whose wealth is based on manufactures and trade. Missouri is the leading manufacturing state west of the Mississippi. Between 1880 and 1900 the value of the product increased from $165,386,205 to $385,492,784, of which $316,304,095 was the value of products of the "factory system"; in 1905 the factory product was valued at $439,548,957. Of the total output in 1900, three-fourths were made up by the output of St Louis ($233,629,733; of which $193,732,788 was from establishments under the "factory system"), Kansas City ($36,527,392; $23,588,653 being "factory product"), St Joseph ($31,690,736, including the product of some establishments outside the city limits; $11,361,939 being "factory product" within the city limits), and Springfield ($4,126,871; $3,433,800 being "factory product"); for the same four cities in 1905 the proportion of the state's total product ($439,548,957) manufactured under the "factory system" is smaller, and less than three-fourths was made up by the following seven cities: St Louis ($267,307,038), Kansas City ($35,573,049), St Joseph ($11,573,720), Springfield ($5,293,315), Hannibal ($4,442,099), Jefferson City ($3,926,632), and Joplin ($3,006,203). In 1905 the eleven municipalities with a population of at least 8000 each (including the seven above, and Carthage, Moberly, Sedalia and Webb City) produced, under the "factory system,") goods valued at $335,431,978. Eighteen industries in 1905 employed nearly three-fifths of the wage-earners in factories and were represented by nearly two-thirds ($293,882,705) of the total product. The most prominent items in this were slaughtering and meat-packing products (value $60,031,133 in 1905); tobacco (in 1905, $30,884,182), flour and grist-mill products (in 1905, $38,026,142),[1] malt liquors (in 1905, $24,154,264), boots and shoes (in 1905, $23,493,552), lumber and timber products (in 1905, $10,903,783), men's factory-made clothing (in 1905, $8,872,831), and cars and general shop construction and repairs by steam railways (1905, $8,720,433). The increase in the slaughtering industry between 1890 and 1900 (134·9%) was chiefly due to remarkable growth in St Joseph—or, to be more precise, just outside the city limits of St Joseph; between 1900 and 1905 the increase was 39·5%. Although Missouri is not a great tobacco state, St Louis is one of the greatest centres of the country in the output of tobacco products. It is also, for the state, the great centre of all the leading interests with the exception of slaughtering. The boot and shoe industry is new west of the Mississippi, but Missouri holds in it a high and rising rank. In the Joplin mining region a considerable amount of ores is smelted, but the bulk of the ores is sent into Kansas for smelting. The finer clays, also, are mainly shipped from the state in natural form, but in the manufacture of sewer-pipe and fire-brick, Missouri is a very prominent state. St Louis and Kansas City are the centres of the clay industries.

Communications.—In 1900 rather under a fifth of the working population were engaged in trade and transportation. In commerce as well as in manufactures St Louis is first among the cities of the state, but Kansas City also is one of the greatest railway centres of the country, and the trade with the south-west, which St Louis once held almost undisputed, has been greatly cut into by Kansas City, as well as by Galveston and other ports on the Gulf. There is still considerable commerce on the Mississippi from St Louis to New Orleans, and a few passenger steamers are still in service. In 1906-1907 there was a notable agitation for improvement, following trial voyages that proved the navigability of the Missouri up to Kansas City. For this part of the river the maximum draft at mean low water was 4 ft. in 1908. In 1907 the amount of freight carried from the mouth of the Missouri to Sioux City, Iowa, was 843,863 tons, and river rates were about 60% of railway rates. In 1907 estimates were made for 6 ft. and 12 ft. channels from Sioux City to Kansas City, and from Kansas City to the mouth of the river. The improvement of the Missouri—which is far more difficult to navigate than the Mississippi—was begun by Congress in 1832, and (in addition to large joint appropriations for the Missouri, Mississippi, Arkansas and Ohio rivers from 1832 to 1882) cost $11,130,560 between 1876 and 1900. Also $65,000 was expended from 1852 to 1876. In nothing except the freighting of bulky and imperishable products, like cotton, coal and cereals, was the river ever able to contest the monopoly of the railways. The mileage of these within the state rose from 3960 in 1880 to 6142 in 1890, and to 8023·94 in 1908; the Missouri Pacific being far the greatest system of the state. St Louis, Kansas City and St Joseph are ports of entry for foreign commerce.

Population.—The total population of Missouri in 1900 was 3,106,665 and in 1910, 3,293,335. The population in 1810 was 20,845; in 1820, 66,586; in 1830, 140,455; in 1840, 383,702; in 1850, 682,044; in 1860, 1,182,012; in 1870, 1,721,295; in 1880, 2,168,380; and in 1890, 2,679,184. Thus, even in the years of the Civil War, there was no apparent set-back. Of the aggregate of 1900, 63·7 % lived in "rural districts" (*i.e.* those outside all places of a population of 2500 or upwards), and 27·1 % in the three great cities of the state, St Louis (pop. 575,238), Kansas City (163,752) and St Joseph (102,979); 5·2 % were negroes—their increase from 1890 to 1900 being less than half as rapid as that of the whites; and 7·0 % only were foreign-born. Slightly more than half of all foreigners are Germans; Irish, English and Scotch, French and English Canadians, Swiss and Scandinavians following. The German element is, and has been since about 1850, of great importance—an importance not indicated at all by its apparently small strength in the population to-day. The German immigration began about 1845, and long ago passed its maximum, so that in 1900 more than half of all the foreign-born (not only the Germans, but also the later-coming nationalities) had lived within Missouri for more than twenty years, and more than three-fourths of all had been residents of the state for ten years or more. Thus the foreign element is an old one, and other statistics show that it is being effectively absorbed into the native mass by intermarriage.[1] The German influence has been felt in education and in the anti-slavery cause. The early settlers of the state were practically all from Kentucky, Tennessee, Virginia and the old slave-states of the south-east, and their influence was easily dominant in the state until well after the Civil War (about 1875), when northerners first began to enter the state in large numbers. The south-western Ozarks were settled originally by mountaineers from Kentucky and Tennessee, and retained a character of social primitiveness and industrial backwardness until after the Civil War. This region has been industrially regenerated by the mine development. In addition to St Louis,[2] Kansas City and St Joseph, the leading cities in 1900 were Joplin, Springfield, Sedalia, Hannibal, Jefferson City, Carthage, Webb City and Moberly.

---

[1] Omitting here printing and publishing, and foundry and machine-shop products, which (like carpentering, bakery products, &c., in cities) have little distinctive in them to set Missouri off from other states. But it is to be noted that St Louis is one of the leading producers of street-railway cars.

As Missouri was originally a French colony the Roman Catholic is its oldest church; and it is still the strongest with 382,642 communicants in 1906 out of a total of 1,199,239 for all denominations. In the same year there were 218,353 Baptists, 214,004 Methodists, 166,137 Disciples of Christ, 71,599 Presbyterians, 45,018 Lutherans, and 32,715 members of the German Evangelical Synod of North America.

Administration.—Three constitutions, framed by conventions in 1820, 1865 and 1875, have been adopted by the people of the state, and a fourth (1845) was rejected, principally because it provided for popular election of the state judiciary, which was then appointed. In addition to these four constitutional conventions, mention should be made of the special body chosen in 1861 to decide the question of secession, which retained supreme though irregular control of the state during the Civil War, and some of whose acts had all the force of promulgated constitutional amendments. Universal manhood suffrage was established by the first constitution. The constitution of 1865 was a partisan and intolerant document, a part of the evil aftermath of war; it was adopted by an insignificant majority and never had any strength in public sentiment.[3] The present constitution (that of 1875) was a notable piece of work when framed. The term of the governor and other chief executive officers, which had been four years until the adoption of the constitution of 1865, under which it was two years, was restored to the long term (unusual in American practice). The legislature (or, as it is called in Missouri, General Assembly) had been permitted to hold adjourned sessions under the constitution of 1865. This expensive practice was abolished; various checks were placed upon legislative extravagance, and upon financial, special and local legislation generally; and among reform provisions, common enough to-day, but uncommon in 1875, were those forbidding the General Assembly to make irrevocable grants of special privileges and immunities; requiring finance officials of the state to clear their accounts precedent to further eligibility to public office; preventing private gain to state officials through the deposit of public moneys in banks, or otherwise; and permitting the governor to veto specific items in general appropriation bills. The grand jury was reduced to twelve members, and nine concurring may indict. The township system may be adopted by county option, but has not been widely established, though purely administrative (not corporate) "townships" are an essential part of state administration. St Louis and Kansas City have adopted their own charters under constitutional provision. Up to 1909 37 constitutional amendments were submitted to the people for adoption or rejection, and 22 were adopted. Three of these (1900) restrict the calling of the grand jury, permit two-thirds of a petit jury to render verdicts in courts not of record, and three-fourths to give verdict in civil cases in courts of record. Cities have been allowed (1892), upon authorization by the General Assembly, to organize pension systems for disabled firemen, but not allowed (1904) to organize the same for police forces. An amendment which was adopted (177,615 for; 147,290 against) in November 1908, and came in effect on the 4th of December 1908, provides for initiative and referendum applying to statutory law and to constitutional amendments, but emergency measures, and appropriations for the state government, for state institutions, and for public schools are exempt from referendum. Initiative petitions, signed by at least 8% of the legal voters in each of two-thirds (at least) of the congressional districts of the state, must be filed not later than four months before the election at which the measure is to be voted upon. The referendum may be ordered by the legislature or by a petition signed by at least 5% of the legal voters in each of two-thirds (at least) of the congressional districts of the state; such petition must be filed not more than 90 days after the final adjournment of the legislature; referred measures become law upon receiving a favourable majority of the popular vote. Among defeated amendments that are indicative of socio-political tendencies was one (1896) to authorize cities of a population of 30,000 or more to purchase, erect or maintain waterworks or lighting plants.

There is nothing extraordinary in the general judicial system. The civil law seems to have had only a tacit, and as soon as American immigration began a limited, application. The common law was introduced with the American settler, and after 1804 was the explicitly declared basis of judicature. Practically no trace of French and Spanish administration was left except in the land registers. The metropolitan primacy of St Louis and Kansas City is reflected in the general organization of the courts. The Bureau of Labor Statistics maintains free employment-bureaus in St Louis, Kansas City and St Joseph. There is also a State Board of Mediation and Arbitration to settle labour disputes. A Board of Railroad and Warehouse Commissioners, elected by the people, was established in 1875, under a provision of the constitution requiring the General Assembly to establish maximum rates and provide against discriminations.[4]

The homestead of a housekeeper or head of a family, together with the rents and products of the same, is exempt from levy and attachment except to satisfy its liabilities at the time he acquired it. A homestead so exempted is, however, limited to 18 sq. rods of ground and to $3000 in value if it is in a city having a population of 40,000 or more, to 30 sq. rods and $1500 in value if it is in a city having a population of 10,000 and less than 40,000, to 5 acres and $1500 in value if it is in an incorporated place having a population of less than 10,000, and to 160 acres and $1500 in value if it is in the country. A husband owning a homestead is debarred from selling or mortgaging it without the joinder of his wife, and if the husband dies leaving a widow or minor children the homestead passes to either or to both jointly, and may be so held until the youngest child is twenty-one years of age or until the marriage or death of the widow. The principal grounds for divorce are impotence, bigamy, adultery, conviction of felony or other infamous crime subsequent to the marriage or before the marriage if unknown to the other party, desertion or habitual drunkenness for one year, such cruel or barbarous treatment as to endanger the life of the other, such conduct as to render the condition of the other intolerable, and vagrancy of the husband; but before applying for a divorce the plaintiff must reside in the state for one year immediately preceding, unless the cause of action was given within the state or while the plaintiff was a resident of the state. A married woman may hold and manage property as if she were single. She is entitled to the wages for her separate labour and that of her children, and is not liable for her husband's debts. A widow has a dower right to one-third of her husband's real estate and to the share of a child in his personal estate. If a husband dies without leaving children or other descendants, the widow is entitled to all the real and personal estate which came to him by marriage, to what remains of the personal property which came into his possession by the written consent of his wife, and to one-half his other real and personal property at the time of his death. If a husband dies leaving descendants only by a former marriage, the widow may take in lieu of dower the personal property that came to him by means of marriage, or if there be children by both marriages she may take in lieu of her dower right to his real estate an absolute right therein equivalent to the share of a child. Her dower is not lost by a divorce resulting from the fault or misconduct of the husband. A widower is entitled to a share in his wife's personal estate equal to the share of a child, and if there are no descendants he has an absolute right to one-half of her property, both real and personal.

---

[1] In 1900 only one person in six had both parents of foreign birth.

[2] St Louis was the capital in 1812–1820, St Charles in 1820–1826, and Jefferson City since 1826.

[3] After the proscriptive features of this constitution were abolished by amendments in 1870, however, there was no great discontent, and the vote for holding a constitutional convention in 1875 was very close: 111,299 to 111,016.

[4] In 1907, in Missouri, as in various other states, passenger rates were reduced by law to 2 cents per mile; but this law was declared unconstitutional in 1909.

Finance.—Revenue is drawn mainly from a general property tax. In 1904 the gross valuation of all taxable wealth was put at $1,155,402,647, and taxation for state purposes aggregated $0.17 per $1000.[1] In the years 1851–1857 a debt of $23,701,000 was incurred in aiding railways, and all the roads made default during the Civil War. The state could not meet its guarantee obligations (hence the strict bonding provisions of the constitution of 1875), and in 1865 had a bonded debt of above $36,000,000. This was reduced to $21,675,000 by 1869, and in 1903 was wholly extinguished, every obligation having been fully discharged. A small debt[2] (at the close of 1906, $4,398,839) is carried in the form of non-negotiable state certificates of indebtedness issued in exchange for money taken from the educational funds of the state, and is intended as a permanent obligation to those funds. An amendment to the constitution adopted in 1908 permitted counties to make an extra levy of 25 cents on each 100 dollars valuation for the construction and repair of roads and bridges.

Charitable and Penal Institutions.—The charitable and penal institutions of the state include the penitentiary at Jefferson City, opened in 1836, which is self-supporting; a training school for boys at Boonville (opened 1889), an industrial home for girls at Chillicothe (established 1887), hospitals for the insane at Fulton (1847), St Joseph (opened 1874), Nevada (1887), and Farmington (1899); a school for the blind at St Louis (opened 1851); a school for the deaf at Fulton (opened 1851); a colony for the feeble-minded and epileptic at Marshall (established 1899); a state sanitorium, for consumptives, at Mount Vernon (established 1905, opened 1907); a Federal soldiers' home at St James, and a Confederate soldiers' home at Higginsville (both established 1897).

Education.—The expenditure upon public schools is much greater in Missouri than in any other of the old slave states. Most of the total expenditure (in 1908, $12,769,690) is made possible by local taxation. The percentage of the enumerated school-population (children 6 to 20 years of age) attending school in 1908 was 48, and the percentage of the total enumeration enrolled was about 71; the general showing being excellent, and that for negroes remarkably so. Blacks and whites are segregated in all schools. Various high-schools scattered over the state are given over to the negroes; and in 1904 the number of pupils attending these was exceeded only by the corresponding numbers in Texas and Mississippi—states with five- and sixfold the negro population of Missouri. Illiterate persons above 10 years of age constituted in 1900 6·4% of the total population—28·1% of the negroes, 7·1% of the natives, 6·9% of the foreign-born. The idea of providing a university and free local schools as parts of a public school system occurs in the constitution of 1820 (and in the Acts of Congress that prepared the way for statehood), and the occurrence is noteworthy; but the real beginnings of the system scarcely go back further than 1850. Nor was very much progress made until a law was passed in 1853 requiring a quarter of the general yearly revenue of the state to be distributed among the counties for schools. This appropriation was made regularly after 1855 (save in 1861–1867), and since 1875 has rested on a constitutional provision. The maintenance of a free public school system was placed on a firm and broad foundation by the constitution adopted in that year. In the years after 1887 one-third of the total revenue was appropriated to the public common schools; and in 1908 the total appropriation for public schools, normal schools and the state university was about three-fifths of the entire state revenue. Local taxation is another source of the school funds. In 1908 the total school fund, including state, county, township and special district funds, was about $14,000,000, of which the state fund was nearly one-third. The schools of St Louis have a very high reputation.

Among institutions of higher learning the university of Missouri at Columbia is the chief one maintained by the state. It was opened to students in 1841, received aid for the first time from the state in 1867; women were first admitted to the mormal department in 1869, to the academic department in 1870, and soon afterwards to all departments. In addition to the academic department or college proper, the university embraces special schools of pedagogics (1868), agriculture and mechanic arts (1870), mines and metallurgy (1870, at Rolla), law (1872), medicine (1873), fine arts (1878), engineering (1877), military science, commerce, a graduate school of arts and sciences (1896), and a department of journalism (1908). An experiment station supported by the national government was established in 1888, and is part of the school of agriculture. The state Board of Agriculture organizes educational farmers' institutes; and agriculture is taught, moreover, in the normal schools of the state. Of these five are maintained as follows: at Kirksville (1870), at Warrensburg (established 1870), at Cape Girardeau (established 1873), at Springfield (established 1905), at Maryville (established 1905), and there is a normal department in connexion with the Lincoln Institute, for negroes, at Jefferson City. Lincoln Institute (opened in 1866) is for negro men and women. The basis of its endowment was a fund of $6379 contributed in 1866 by the 62nd and 65th regiments U.S. Colored Infantry upon their discharge from the service; it has agricultural, industrial, sub-normal, normal and collegiate departments. Among privately endowed schools the greatest is Washington University in St Louis; it is non-sectarian and was opened in 1857. Noteworthy, too, is the St Louis University, opened in 1829, the oldest institution for higher learning west of the Mississippi; it is a Jesuit college and the parent school of six other Jesuit institutions in the states of the middle west. There are many minor colleges and schools, most of them co-educational, and special colleges or academies for women are maintained by different religious sects. Finally, there are various professional schools, most of them in St Louis and Kansas City.

History.—The early French explorers of the Mississippi valley left the first trace of European connexion in the history of Missouri. Ste Genevieve was settled in 1735; Fort Orleans, two-thirds of the way across the state up the Missouri river, had been temporarily established in 1720; the famous Mine La Motte, in Madison county, was opened about the same time; and before the settlement of St Louis, the Missouri river was known to trappers and hunters for hundreds of miles above its mouth. It was in 1764 that St Louis (*q.v.*) was founded. Two years before, the portion of Louisiana west of the Mississippi had secretly passed to Spain, and in 1763 the portion east passed to England. When the English took possession a large part of the people in the old French settlements removed west of the river. Not until 1770, after O'Reilly had established Spanish rule by force at New Orleans, did a Spanish officer at St Louis take actual possession of the upper country; another on the ground, in 1768–1769, had forborne to assert his powers in the face of the unfriendly attitude of the inhabitants. Spanish administration began in 1771. French remained the official language, and administration was so little altered that the people quickly grew reconciled to their changed allegiance. Settlement was confined to a fringe of villages along the Mississippi. French-Canadian hunters and trappers, and soon the river boatmen, added an element of adventure and colour in the primitive life of the colony. Lead and salt and peltries were sent to Montreal, New Orleans, and up the Ohio river to the Atlantic cities.

The Americans were hospitably received; the immigrants, even Protestant clergymen, enjoyed by official goodwill complete religious toleration; and after about 1796 lavish land grants to Americans were made by the authorities, who wished to strengthen the colony against anticipated attacks by the British, from Canada. Kentucky, Tennessee and Virginia furnished most of the new-comers. The French had lived in villages and maintained considerable communal life; the Americans scattered on homesteads. With them came land speculation, litigiousness, the development of mines and mining-camp law, and the passion of politics, of which duels were one feature of early days. In 1804 there were some 10,000 inhabitants in Upper Louisiana (mainly in Missouri), and of these three-fifths were Americans and their negroes. Racial antipathies were unimportant, and all parties were at least passively acquiescent when Louisiana became a part of the United States. On the 9th of March 1804, at St Louis, Upper Louisiana was formally transferred. In 1818, after passing meanwhile through four stages of limited self-government,[3] that portion of the Purchase now included in the state of Missouri made application for admission to the Union as a state.[4] In 1812–1813 a remarkable earthquake devastated the region about New Madrid. A large region was sunken, enormous fissures were opened in the earth, the surface soil was displaced and altered, and great lakes were formed along the Mississippi. One of these, Reelfoot Lake, east of the river, is 20 m. long and 7 wide, and so deep that boats sail over the submerged tops of tall trees. Indian troubles again disturbed the peace during the second war with Great Britain. By 1808 the Indian title was extinguished to two-thirds of the state, though actual settlement did not extend more than a few miles westward from the Mississippi; in 1825, by a treaty with the Shawnee made at St Louis on the 7th of November, the title to the rest of the state was cleared, and a general removal of the Indians followed. Meanwhile, after the peace of 1815 a great immigration had set in, many settlers coming from the free states north of the Ohio. The application for statehood precipitated one of the most famous and significant episodes of national history—the Missouri Compromise (*q.v.*). In August 1821, after three years of bitter controversy, Missouri was formally admitted to statehood.

---

[1] The constitutional provision requiring assessments at cash valuations is not at all observed; according to the State Revenue Commission of 1902 the average tax valuation was 40 to 50% of the real value. The national censuses of 1880 and 1890 (no estimate being made in 1900) put the total value of all property at $1,562,000,000 and $2,397,902,945 respectively.

[2] In 1902 the bonded debts of counties and townships aggregated $8,066,878; that of towns and cities (mostly that of St Louis), $31,193,870.

[3] In 1804, the District of Louisiana, in the administrative system of the Territory of Indiana; in 1805, an independent government, renamed the Territory of Louisiana; in 1812, the Territory of Missouri; in 1816, another grade of territorial government.

[4] Until 1836 the state boundary in the north-west was the meridian of the mouth of the Kansas river drawn due north to the Iowa line. The addition of the triangle west of that line—the so-called Platte Purchase—violated the Missouri Compromise.

In the four decades before the Civil War, two matters stand out as most distinctive in the history of the state: the trouble with the Mormons, and the growth of river and prairie trade. In 1831–1832 Joseph Smith, the Mormon leader, selected a tract at the mouth of the Kansas river as the site of the New Jerusalem, to which his followers came from Ohio in 1832. They were not welcome. Their "revelations" in their papers predicted dire things for the Gentiles; they were thrifty and well-to-do, and were rapidly widening their lands: they were accused of disregard for Gentile property titles, and they obstructed the processes of Gentile law within their lands. In 1833 the Missourians, in mass meeting, resolved to drive them from the country. The five years thereafter were marked by plunder and abuse of the sect. The militia and the courts gave them no protection. They were driven out, and went to Illinois, but continued to hold part of their abandoned lands. First St Louis, and then other towns on the Missouri river in succession westward, as they were settled and became available as dépôts, served as the outfit points for the Indian trade up the Missouri and the trade with Mexico through Santa Fé. The trail followed by the latter had its beginning about 1812, and (beginning in 1825) was surveyed by the national government. In early days Mexican and American military detachments escorted the caravans on either side of the international line. Independence, Missouri (after about 1831) and Kansas City (after 1844) were the great centres of this trade, which by 1860 was of national importance.[1] After the Civil War the railways gradually destroyed it, the Atchison Topeka & Santa Fé railroad running along the old wagon trail. No steamer traversed the Mississippi above the Ohio until 1817, nor was a voyage made between New Orleans and St Louis, nor the lower Missouri entered, until 1819. In 1832 a steamer ran to the mouth of the Yellowstone, and in 1890 the last commercial trip was made to old Fort Benton (Great Falls), Montana. The interval of years witnessed the growth of a river trade and its gradual decline as point after point on the river—Kansas City, St Joseph, Council Bluffs (Iowa), Sioux Falls (South Dakota) and Helena (Montana)—was reached and commanded by the railways. In 1906–1907 an active campaign was begun at Kansas City for improving the channel of the Missouri and stimulating river freighting below that point.

Among events leading up to the Civil War, first the annexation of Texas and then the war with Mexico left special impress on Missouri history. Since 1828, when national political parties were first thoroughly organized in the state, the Democrats had been supreme, and carried Missouri on the pro-slavery side of every issue of free and slave territory. But there was always a strong body of anti-slavery sentiment,[2] nevertheless; and this took organized form in 1849, when Senator Benton repudiated certain ultra pro-slavery instructions, breathing a secession spirit, passed by the General Assembly for the guidance of the representatives of the state in Congress. From that time until his death he organized and led the anti-disunion party of the state, Francis Preston Blair, jun., succeeding him as leader. The struggle over Kansas (*q.v.*) aroused tremendous passion in Missouri. Her border counties furnished the bogus citizens who invaded Kansas to carry the first territorial elections, and soon guerrilla forays back and forth gave over the border to a carnival of crime and plunder. Political conditions were chaotic. In the presidential election of 1860, Douglas received the electoral vote of the state, the only one he carried in the Union. The Republicans had little strength outside St Louis, where the German element was strong. A party led by Claiborne F. Jackson, the governor-elect, was resolved to carry the state out of the Union. Such secession, it was supposed, would carry the other border states out also. With equal blindness the Secessionists favoured, and the Republicans opposed, the calling of a special state convention to decide the issue of secession. The election showed that popular sentiment was overwhelmingly hostile to secession; and the convention, by a vote of 80 to 1, resolved (March 4, 1861) that Missouri had "no adequate cause" therefor. Governor Jackson thereupon sought to attain his ends by intrigue, and the national arsenal at St Louis became the objective of both parties. It was won by the unconditional-union men, but a smaller arsenal at Liberty was seized by the Secessionists. Governor Jackson refused point-blank to contribute the quota of troops from Missouri called for by President Lincoln. Aggressive conflict really opened at St Louis on the 10th of May, and armed hostilities began in June. On the 10th of August 1861 at Wilson's Creek, near Springfield, General Nathaniel Lyon was defeated by a superior Confederate force in one of the bloodiest battles of the war. After this the Confederates held much of southern Missouri until the next spring, when they were driven into Arkansas, never afterward regaining foothold in the state. In the autumn of 1864 Sterling Price led a brilliant but rather bootless Confederate raid across the state, along the Missouri River, and was only forced to retreat southward by defeat at Westport (Kansas City). The western border was rendered desolate and deserted by guerrilla forays throughout the war. Probably 25,000 or 30,000 soldiers served in the Confederate armies, and 109,111 were furnished to the Union arms.[3] This was a remarkable showing. There was more or less internecine conflict throughout the war, and local disaffection under Union rule; and Confederate recruiting was carried on even north of the Missouri.

Altogether, the state offered a difficult civil and military problem throughout the Civil War. An emancipation proclamation issued by General J. C. Frémont at St Louis in August 1861, though promptly disavowed by President Lincoln, precipitated the issue. The state convention, after voting against secession, had adjourned, and after various sessions was dissolved in October 1863. Assuming revolutionary powers, it deposed Governor Jackson and other state officers, appointed their successors, declared vacant the seats of members of the Assembly, and abrogated the disloyal acts of that body. In October 1861 a rump of the deposed Assembly passed an act of secession, which the Confederate States saw fit to regard as legitimate, and under which they admitted Missouri to their union by declaration of the 28th of November. In 1862 the convention rejected the President's suggestion of gradual emancipation, disfranchised Secessionists, and prepared a strong oath of allegiance. In the summer of 1863 the convention decreed emancipation with compensation to owners. This did not satisfy the Radical Republicans, and on the issue of immediate and unconditional emancipation they swept the state in November 1864. By the constitution of 1865 slavery was abolished outright.[1] The convention of 1861, by maintaining continuous government, had saved the state from anarchy and from reconstruction by the national power; but an ironclad test oath (it required denial of forty-five distinct offences) was provided, to be taken by all voters, state, county and municipal officers, lawyers, jurors, teachers and clergymen. Its attempted enforcement was a grave error of judgment, and was attended by great abuses, and it was finally held unconstitutional by the United States Supreme Court. The legislature, however, maintained its ends by registration laws that reduced to impotence the Democratic electorate. The Radical Republicans held control until 1870, when they were defeated by a combination of Liberal Republicans and Democrats,[2] and the test-oath and the rest of the intolerant legislation of the war period were swept away. In 1872 the Democrats gained substantial control, and after 1876 their power was established beyond challenge. The constitution of 1875 closed the war period with blanket amnesties. Though in politics habitually Democratic, Missouri has generally had a strong opposition party—Whig in antebellum days, and since the war, Republican—which in recent years has made political conditions increasingly unstable. This instability is shown in congressional and local rather than in general state elections. In 1908 a Republican governor was elected, the first for more than thirty years.

---

[1] In 1855 its value was estimated at $5,000,000. In 1860 it was much greater. In the latter year the trade employed 3000 wagons, 62,000 oxen and mules, and 7000 men.

[2] Under the constitution of 1820 the General Assembly had power to emancipate the slaves with the consent of their masters. In 1828 Senator T. H. Benton and others prepared a plan for educating the slaves and gradually emancipating them under state law; and undoubtedly a considerable party would have supported such a project, for the Whigs and Democrats were not then divided along party lines on the slavery issue; but nothing came of the plan, and the manner of its defeat proves that it could not possibly have been pushed to success. The trouble over Lovejoy's printing office at St Louis (1833–1836) put an effectual end to the movement for emancipation.

[3] Compare the vote of 1861. The Union death-roll of Massachusetts (troops furnished, 159,165) was 13,942, that of Missouri 13,887.

The Governors of Missouri since 1804 have been as follow:—

Territorial Period.

	Party Affiliation.	Service.
James Wilkinson	Appointed	1805–1806
Joseph Brown (acting governor)		1806–1807
Frederick Bates " "		1807
Meriwether Lewis	Appointed	1807–1809
Frederick Bates (acting governor)		1809–1810
Benjamin Howard	Appointed	1810–1812
Frederick Bates (acting governor)		1812–1813
William Clark	Appointed	1813–1820
State Period.		
Alexander McNair	Democrat	1820–1824[3]
Frederick Bates (died in office)	"	1824–1825
Abraham J. Williams (acting governor)		1825
John Miller (special election to fill out term)	Democrat	1825–1828
John Miller	"	1828–1832
Daniel Dunklin (resigned office)	"	1832–1836
Lilburn W. Boggs (acting governor)		1836
Lilburn W. Boggs	Democrat	1836–1840
Thomas Reynolds (died in office)	"	1840–1844
M. M. Marmaduke (acting governor)		1844
John C. Edwards	Democrat	1844–1848
Austin A. King	"	1848–1853
Sterling Price	"	1853–1857
Trusten Polk (elected to United States Senate)	"	1857
Hancock Jackson (acting governor)		1857
Robert M. Stewart (elected to serve out term)	Democrat	1857–1861
Claiborne F. Jackson (deposed by state convention)	"	1861
Hamilton R. Gamble (appointed by state convention; died in office), provisional governor		1861–1864
Willard P. Hall (Lieut.-governor by same power, acting provisional governor)		1864–1865
Thomas C. Fletcher	Republican	1865–1869
Joseph W. McClurg	"	1869–1871
B. Gratz Brown	Liberal Republican (and Democrat)	1871–1873
Silas Woodson	"	1873–1875
Charles H. Hardin	Democrat	1875–1877
John S. Phelps	"	1877–1881
Thomas T. Crittenden	"	1881–1885
John S. Marmaduke (died in office)	"	1885–1887
Albert P. Morehouse (acting governor)		1887–1889
David R. Francis	Democrat	1889–1893
William J. Stone	"	1893–1897
Lon V. Stephens	"	1897–1901
Alexander M. Dockerey	"	1901–1905
Joseph W. Folk	"	1905–1909
Herbert S. Hadley	Republican	1909

Durrie, *An Illustrated History of Missouri* (St Louis, 1876); *Encyclopedia of the History of Missouri* . . . ed. by H. L. Conrad (6 vols., New York, St Louis, 1901).

MISSOURI COMPROMISE, an agreement (1820) between the pro-slavery and anti-slavery factions in the United States, involving primarily the regulation of slavery in the public territories. A bill to enable the people of Missouri to form a state government preliminary to admission into the Union came before the House of Representatives in Committee of the Whole, on the 13th of February 1819. An amendment offered by James Tallmadge (1778–1853) of New York, which provided that the further introduction of slaves into Missouri should be forbidden, and that all children of slave parents born in the state after its admission should be free at the age of twenty-five, was adopted by the committee and incorporated in the Bill as finally passed (Feb. 17) by the house. The Senate refused to concur in the amendment and the whole measure was lost. During the following session (1819–1820), the house passed a similar bill with an amendment introduced on the 26th of January 1820 by John W. Taylor (1784–1854) of New York making the admission of the state conditional upon its adoption of a constitution prohibiting slavery. In the meantime the question had been complicated by the admission in December of Alabama, a slave state (the number of slave and free states now becoming equal), and by the passage through the house (Jan. 3, 1820) of a bill to admit Maine, a free state. The Senate decided to connect the two measures, and passed a bill for the admission of Maine with an amendment enabling the people of Missouri to form a state constitution. Before the bill was returned to the house a second amendment was adopted on the motion of J. B. Thomas (1777–1850) of Illinois, excluding slavery from the "Louisiana Purchase" north of 36° 30′ (the southern boundary of Missouri), except within the limits of the proposed state of Missouri. The House of Representatives refused to accept this and a conference committee was appointed. There was now a controversy between the two houses not only on the slavery issue, but also on the parliamentary question of the inclusion of Maine and Missouri within the same bill. The committee recommended the enactment of two laws, one for the admission of Maine, the other an enabling act for Missouri without any restrictions on slavery but including the Thomas amendment. This was agreed to by both houses, and the measures were passed, and were signed by President Monroe respectively on the 3rd and on the 6th of March 1820. When the question of the final admission of Missouri came up during the session of 1820–1821 the struggle was revived over a clause in the new constitution (1820) requiring the exclusion of free negroes and mulattoes from the state. Through the influence of Henry Clay an act of admission was finally passed, to come into operation as soon as the state legislature would pledge itself not to pass any legislation to enforce this clause. This is sometimes known as the second Missouri Compromise.

---

[1] Thus liberating about 114,000 blacks, of a tax valuation of $40,000,000.

[2] The Liberals were those who thought unjust the proscriptionary legislation passed against the Secessionists and Democrats; and to this issue of local politics were added the issues of national reform which the course of President Grant's administration had forced upon his party. A convention of Liberals that met at Jefferson City in January 1872 issued to all Republicans favourable to reform within the party an invitation to meet at Cincinnati in May; and this was the convention of revolters against General Grant that nominated Horace Greeley of New York and B. Gratz Brown of Missouri as Liberal Republican candidates for the presidency and vice-presidency respectively. The first definite organization of the Liberal Republican party may therefore be said to have been made in Missouri in 1870.

[3] From 1820–1844 the elections were in August and inaugurations in November; Governor King served from the 27th of December 1848 till January 1853; thereafter the inauguration was in January, and beginning with 1864 the election was in November. The term was four years except under the constitution of 1865.

These disputes, involving as they did the question of the relative powers of Congress and the states, tended to turn the Democratic-Republicans, who were becoming nationalized, back again toward their old state sovereignty principles—to prepare the way for the Jacksonian-Democratic Party. On the other hand, the old Federalist nationalistic element was soon to emerge first as National Republicans, then as Whigs, and finally as Republicans. On the constitutional side the Compromise of 1820 was important as the first precedent for the congressional exclusion of slavery from public territory acquired since the adoption of the Constitution, and also as a clear recognition that Congress has no right to impose upon a state asking for admission into the Union conditions which do not apply to those states already in the Union. The compromise was specifically repealed by the Kansas-Nebraska Bill of 1854.

See J. A. Woodburn, "The Historical Significance of the Missouri Compromise" in the *Annual Report of the American Historical Association* for 1893 (Washington, D.C.); Dixon, *History of the Missouri Compromise* (Cincinnati, 1899); Schouler's and McMaster's *Histories of the United States.* (W. R. S*.)

MISSOURI RIVER, the principal western tributary of the Mississippi river, U.S.A. It is formed at Gallatin City, in the Rocky Mountain region of south-western Montana, by the confluence of the Jefferson, Madison and Gallatin forks; thence it flows N. into the plains, which it traverses in a course at first N.E., then E. Entering North Dakota, the river turns gradually to the S.E., then S., and again S.E., traversing both North and South Dakota. It forms the eastern boundary of Nebraska and in part of Kansas, and crosses Missouri in an easterly course to its junction with the Mississippi 20 m. above St Louis, and 2547 m. below the confluence of the three forks. The stream which is known as the Jefferson Fork in its lower course, Beaver Head River in its middle course, and Red Rock Creek in its upper course, is really the upper section of the Missouri; it rises on the border between Montana and Idaho, 20 m. west of the western boundary of the Yellowstone National Park, near the crest of the Rocky Mountains, 8000 ft. above the sea, and 398 m. beyond Gallatin City; and with this and the Lower Mississippi the Missouri forms a river channel 4221 m. in length, the longest in the world. The Madison and Gallatin forks rise within the Yellowstone Park, where the former is fed by geysers and hot springs and the latter by both hot springs and melting snow. The Yellowstone river, which is the principal tributary of the Missouri, traverses the park. The Missouri drains a basin having an area of about 580,000 sq.m.; this includes the eastern slope of the Rocky Mountains from the northern border of the United States to the middle of Colorado, and its larger tributaries take their rise in those mountains. Besides the Yellowstone and the three forks there are the Platte, which rises in two large branches in Colorado, and the Milk, which rises in north-western Montana. The Kansas in Kansas, the James and Big Sioux in the Dakotas, and the Niobrara in Nebraska, are the principal tributaries wholly of the plains. In the mountain region the Missouri flows through deep canyons and over several cascades. Below Great Falls the slower current is unable to carry all the silt brought down from the mountains and plains; and consequently a winding and unstable channel has been formed on deposits of silt 50 to 100 ft. or more in depth. Bends in the river continue to develop by erosion until the neck between two of them is cut off, and in the process numerous islands, sand-bars, and crescent-shaped lakes are formed. Cottonwood, willow, cedar and walnut trees grow upon the banks that are for a time left undisturbed, but years later the eroding current returns to undermine these banks, the trees fall in and are carried down stream as snags (or "sawyers"), which are especially dangerous to navigation. The variation of level is great and it varies greatly in different parts of the river's course: it is about 19 ft. at Kansas City, about 25 ft. at St Charles, Missouri, and about 8 ft. at Fort Benton, Montana. It is estimated that the Missouri's average discharge per second amounts to about 94,000 cub. ft., and that each year it carries into the Mississippi 550,000 tons of silt. The waters of the Missouri begin to rise in March, and a high-water stage is reached in April as a result of the spring rains and the melting snow on the plains; a second high stage is produced in June by the melting of snow on the mountains, and the river is navigable from early spring to midsummer as far as Fort Benton, within 40 m. of the Great Falls and 2285 m. above the mouth. Above Great Falls the river is navigable to Three Forks.

The mouth of the Missouri was discovered in 1673 by Marquette and Joliet, while they were coming down the Mississippi. Early in the 18th century French fur-traders began to ascend the river, and in 1764 St Louis was established as a dépôt; but the first exploration of the river from its mouth to its headwaters was made in 1804–1805 by Meriwether Lewis and William Clark. Until many years later the commerce on the river was restricted to the fur trade and was carried on with such primitive craft as the canoe (made from the log of a cottonwood tree); the pirogue (usually two canoes side by side and with a floor over them on which to place the cargo); the bullboat (made by covering a framework of willow poles with the hides of bison bulls); the mackinaw boat (made of boards and having a flat bottom); and the keelboat (a vessel of some pretensions, with a keel from bow to stern, 60 to 70 ft. in length, with a breadth of beam from 15 to 18 ft., and drawing 20 to 30 in. of water). A canoe, pirogue, bullboat, or mackinaw boat was propelled by two or more men with paddles, poles, or oars; but to propel a keelboat up the river required 20 to 40 men who walked along the shore and pulled a *corvelle*, a line about 1000 ft. long and fastened to the mast. An average of about 15 m. a day was made with a keelboat going up the river. The first attempt to navigate the Missouri with steamboats was made in the spring of 1819, when the "Independence" made a trip from St Louis to the mouth of the Chariton river and back. The American Fur Company began to use steamers in 1830, and from then until the advent of railways the steamboat on the Missouri was one of the most important factors in the development of the Northwest. The traffic was at its height in 1858, when no fewer than 60 regular packets were engaged in it, but its decline began in the following year with the completion of the Hannibal & St Joseph railway to St Joseph, Missouri, and 20 years later it had nearly disappeared. In an attempt to regulate railway rates, however, four boats were run between Kansas City and St Louis between 1890 and 1894 by the Kansas City & Missouri Transportation Company, and in 1906 the Missouri River Valley Improvement Association was formed at Kansas City. Congress began to make appropriation for the removal of snags about 1838, and forty years later appropriations were begun for a general improvement which in 1884 was placed under the charge of the Missouri River Commission. In 1890 its work was restricted to that part of the river below Sioux City and in 1902 the Commission was abolished. Up to the 30th of June 1908 the Federal government had expended $11,398,881 for the improvement of the river.

Brower, *The Missouri River and* *its Utmost Source* (St Paul, 1896); J. M. Hanson, *The Conquest of the Missouri* (New York, 1909); L. M. Jones, "The Improvement of the Missouri River and its Usefulness as a Traffic Route," in *Annals of the American Academy of Political and Social Science* (Jan. 1908), and the *Annual Reports* of the Chief of Engineers, U.S. Army.

MISTAKE (*i.e.* take amiss), a misconception or error in thought or action. In law, the word is often used in the sense of ignorance or error, as when it is said that mistake of law affords no excuse for crime. In the law of contract, mistake is of special importance, and may occur either in a matter of law or in a matter of fact. In general, a mistake of law cannot be alleged in avoidance of the consequences of contracts or acts, although there are exceptions in which relief may be given. Mistake of fact, however, may be ground for avoidance, provided the mistake was not due to negligence. (See further CONTRACT.)

MISTLETOE[1] (*Viscum album*), a species of *Viscum*, of the botanical family Loranthaceae. The whole genus is parasitical, and contains about twenty species, widely distributed in the warmer parts of the old world; but only the mistletoe proper is a native of Europe. It forms an evergreen bush, about 4 ft. in length, thickly crowded with forking branches and opposite leaves, which are about 2 in. long, obovate-lanceolate in shape and yellowish-green; the dioecious flowers, which are small and nearly of the same colour but yellower, appear in February and March; the white berry when ripe is filled with a viscous semi-transparent pulp (whence bird-lime is derived). The mistletoe is parasitic both on deciduous and evergreen trees and shrubs. In England it is most abundant on the apple-tree, but rarely found on the oak. Poplars, willows, lime, mountain-ash, maples, are favourite habitats, and it is also found on many other trees, including cedar of Lebanon and larch. The fruit is eaten by most frugivorous birds, and through their agency, particularly that of the species which is accordingly known as missel-thrush or mistle-thrush, the plant is propagated. The Latin proverb has it that "Turdus malum sibi cacat"; but the sowing is really effected by the bird wiping its beak, to which the seeds adhere, against the bark of the tree on which it has alighted. The viscid pulp soon hardens, affording a protection to the seed; in germination the sucker-root penetrates the bark, and a connexion is established with the vascular tissue of the first plant. The growth of the plant is slow, and its durability proportionately great, its death being determined generally by that of the tree on which it has established itself. The mistletoe so extensively used in England at Christmas is largely derived from the apple orchards of Normandy; a quantity is also sent from the apple orchards of Herefordshire.

Pliny (*H. N.*, xvi. 92–95; xxiv. 6) has a good deal to tell about the *viscum*, a deadly parasite, though slower in its action than ivy. He distinguishes three "genera." "On the fir and larch grows what is called *stelis* in Euboea and *hyphear* in Arcadia." Viscum, called *dryos hyphear*, is most plentiful on the esculent oak, but occurs also on the robur, *Prunus sylvestris* and terebinth. Hyphear is useful for fattening cattle if they are hardy enough to withstand the purgative effect it produces at first; viscum is medicinally of value as an emollient, and in cases of tumour, ulcers and the like. Pliny is also our authority for the reverence in which the mistletoe when found growing on the robur was held by the Druids. Prepared as a draught, it was used as a cure for sterility and a remedy for poisons. The mistletoe figures also in Scandinavian legend as having furnished the material of the arrow with which Balder (the sun-god) was slain by the blind god Höder. Most probably this story had its origin in a particular theory as to the meaning of the word mistletoe.

MISTRAL, FRÉDÉRIC (1830–), Provençal poet, was born at Maillane (Bouches-du-Rhône) on the 8th of September 1830. In the autobiographical sketch prefixed to the *Isclo d'or* (1876) he tells us, with great simplicity and charm, all that is worth knowing of his early life. His father was a prosperous farmer, and his mother a simple and religious woman of the people, who first taught him to love all the songs and legends of the country. In these early days on the farm he received those first impressions which were destined to constitute one of the chief beauties of *Mirèio*. In his ninth year Mistral was sent to a small school at Avignon, where he was very wretched at first, regretting the free outdoor life of the country. Gradually, however, his studies attracted him, above all the poetry of Homer and Virgil; and he translated the latter's first eclogue, showing his efforts to a young schoolfellow, A. Mathieu, who was destined to play a part in the foundation of the Félibrige. When Roumanille (see PROVENÇAL LITERATURE) became an usher at Mistral's school, the two, fired by the same love of poetry and of their native Provence, soon became close friends. "Voilà l'aube que mon âme attendait pour s'éveiller à la lumière," he exclaimed, on reading Roumanille's first dialect poems; and he goes on to say: "Embrasés tous les deux du désir de relever le parler de nos mères, nous étudiâmes ensemble les vieux livres Provençaux, et nous nous proposâmes de restaurer la langue selon ses traditions et caractères nationaux." On leaving school (1847) he returned to Maillane, where he sketched a pastoral poem in four cantos (*Li Meissoun*). With all his love for the country, he soon realized that life on a farm did not satisfy his ambition. So he went to study law at Aix, where he contributed his first published poems to Roumanille's *Li Prouvençalo* (1852). He had become *licencié en droit* the year before, but now decided on a literary career. The Félibrige was founded in 1854, and five years later appeared *Mirèio*, the masterpiece not only of Mistral, but so far of the entire school. The tale itself was nothing—the old story of a rich girl and her poor lover, kept apart by the girl's parents. Mireille, in despair, wanders along a wide tract of country to the church of the Trois-Maries, in the hope that these may aid her. But the effort was too great: she sinks exhausted, and dies in the presence of her stricken parents and her frenzied lover. Into this simple web Mistral has woven descriptions of Provençal life, scenery, character, customs and legends that raise the poem to the dignity of a rustic epic, unique in literature. Nothing is forced: every detail is filled into the framework of the whole with a cunning which the poet was never again to attain. There is no deep psychology in the characters, but then the people depicted are simple rustic folk, who wear their hearts on their sleeve. *Calendau* (1867), the story of a princess held in bondage by a ruthless brigand, and eventually rescued by a youthful hero, is a comparative failure. The description of scenery is again masterly; but the old lore, which had charmed all readers in *Mirèio*, here becomes forced, not inevitable. The characters are mere symbols—indeed the whole poem is obviously an allegory, the princess standing for Provence, the brigand for France, and the young lover for the Félibrige. Mistral lavished enormous labour on this work, which probably accounts for its lack of spontaneity, as also for the love he bears it. In 1876 (the same year in which he married Mlle Marie Rivière, of Dijon) was published the volume *Lis Isclo d'Or*—a collection of the shorter poems Mistral had composed from the year 1848 onwards. Here he is again at his very best. Old legends, *sirventes* (mostly, as in medieval times, poems with a tendency), and lyrics—all are admirable. Even the *pièces d'occasion* may be reckoned with the best of their kind. Two pieces, the *Coupe* and the *Princesse*, aroused violent controversy on their first appearance. They reproduce, in effect, the theme of *Calendau*, and Mistral was accused of trying to sow discord between the north and south of France. Needless to say he was altogether innocent of such a design. *Nerto* (1884) is a charming tale of Avignon in the olden days, in which a girl's purity triumphs over her lover's base designs and leads him to nobler thoughts. There is little individuality in the characters, which should rather be regarded as types; and we feel no terror or pity at the tragic close. But we are carried along by Mistral's art and by the brilliancy of his episodes; and he achieved the object he had in view: a pretty tale imbued with the proper touch of local colour and with the true spirit of romance. The play *La Rèino Jano* (1890) is a complete failure, if judged from the dramatic standpoint: it is rather a brilliant panorama, a series of stage pictures, and the characters neither live nor arouse our sympathy. In the great epic on the Rhone (*Lou Pouèmo dóu Rouse*, 1897) the poet depicts the former barge-life of that river, and intertwines his narrative with the legends clustering round its banks, and with a graceful love episode. For the first time he employs blank verse, and uses it with great mastery, but again the ancient lore is overdone. A splendid piece of work is *Lou Tresor dóu Félibrige* (1886). In these two volumes Mistral has deposited with loving care every word and phrase, every proverb, every scrap of legend, that he had gathered during his many years' journeyings in the south of France. In 1904 he was awarded one of the Nobel prizes for literature.

---

[1] Gr. ἰξία or ἰξός, hence Lat. *viscum*, Ital. *vischio* or *visco*, and Fr. *gui*. The English word is the O.E. *misteltan*, Icelandic *mistelteinn*, in which *tan* or *teinn* means a twig, and *mistel* may be associated either with *mist* in the sense of fog, gloom, because of the prominence of mistletoe in the dark season of the year, or with the same root in the sense of dung (from the character of the berries or the supposed mode of propagation).

An excellent literary appreciation of the poet is that by Gaston Paris, "Frédéric Mistral" (originally in the *Revue de Paris* (Oct. and Nov. 1894); then in *Penseurs et Poètes* (Paris, 1896). More elaborate accounts are Welter, *Frédéric Mistral* (Marburg, 1899); and Downer, *Frédéric Mistral* (New York, 1901), with a full bibliography. (H. O.)

MISTRAL, a local wind similar to the bora (*q.v.*), met with on the French Mediterranean coast. The warm Gulf of the Lion (Golfe du Lion) has to the north the cold central plateau of France, which during winter is commonly a centre of high barometric pressure, and the resulting pressure gradient causes persistent currents of cold dry air from the north-west in the intermediate zone. The mistral occurs along the coast from the mouth of the Ebro to the Gulf of Genoa, but attains greatest strength and frequency in Provence and Languedoc, *i.e.* the district of the Rhone delta, where it blows on an average one day out of two; the record at Marseilles is 175 days in the year. It is usually associated with cloudless skies and brilliant sunshine, intense dryness and piercing cold. With the passage of a cyclone over the gulf, or a rapid rise of pressure following a fall of snow on the central plateau, the mistral develops into a stormy wind of great violence.

MISTRESS (adapted from O. Fr. *maistresse*, mod. *maîtresse*, the feminine of *maistre*, *maître*, master), a woman who has authority, particularly over a household. As a form of address or term of courtesy the word is used in the same sense as "madam." It was formerly used indifferently of married or unmarried women, but now, written in the abbreviated form "Mrs" (pronounced "missis"), it is practically confined to married women and prefixed to the surname; it is frequently retained, however, in the case of spinster cooks or housekeepers, as a title of dignity; as the female equivalent of "master" the word is used in other senses by analogy, *e.g.* of Rome as "the mistress of the world," Venice "the mistress of the Adriatic," &c. From the common use of "master" as a teacher, "mistress" is similarly used. The old usage of the word for a lady-love or sweetheart has degenerated into that of paramour. "Miss" a shortened form of "mistress," is the term of address for a girl or unmarried woman; it is prefixed to the surname in the case of the eldest or only daughter of a family, and to the Christian names in the case of the younger daughters.

MITAU (Russian, *Mitava*; Lettish, *Yelgava*), a town of Russia, capital of the government of Courland, 29 m. by rail S.W. of Riga, on the right bank of the river Aa, in a fertile plain which rises only 12 ft. above sea level, and has probably given its name to the town (*Mitte in der Aue*). Pop. (1897), 35,011 inhabitants, mainly Germans, but including also Jews (6500), Letts (5000) and Russians. At high water the plain and sometimes also the town are inundated. Mitau is surrounded by a canal occupying the place of former fortifications. It has regular, broad streets, bordered with the mansions of the German nobility, who reside at the capital of Courland. Mitau is well provided with educational institutions, and is also the seat of the Lettish Literary Society. The old castle (1266) of the dukes of Courland, situated on an island in the river, was destroyed by Duke Biren, who erected in its place (1738–1772) a spacious palace, now occupied by the governor and the courts. Manufactures are few, those of wax-cloth, linen, soap, ink and beer being the most important.

Mitau is supposed to have been founded in 1266 by Conrad Mandern, grand-master of the order of the Brethren of the Sword. In 1345, when it was plundered by the Lithuanians, it was already an important town. In 1561 it became the residence of the dukes of Courland. During the 17th century it was thrice taken by the Swedes. Russia annexed it with Courland in 1795. It was the residence (1798–1801 and 1804–1807) of the count of Provence (afterwards Louis XVIII.). In 1812 it was taken by Napoleon I.

MITCHAM, a suburb of London, in the Wimbledon parliamentary division of Surrey, England, 10 m. S. of London Bridge by the London, Brighton & South Coast railway. Pop. (1901), 14,903. Mitcham Common covers an area of 480 acres, and affords one of the best golf courses near London. The neighbourhood abounds in market gardens and plantations of aromatic herbs for the manufacture of scents and essences.

MITCHEL, ORMSBY MACKNIGHT (1809–1862), American astronomer, was born at Morganfield, Kentucky, on the 28th of July, 1809. He began life as a clerk, but, obtaining an appointment to a cadetship at West Point in 1825, he graduated there in 1829, and acted as assistant professor of mathematics 1829–1832. He was then called to the bar, but in 1836 became professor of mathematics and natural philosophy at Cincinnati College. In 1845 he was made director of an observatory established there through his initiative, and also in 1859 superintendent of the Dudley observatory at Albany. In 1861 he took part in the war as brigadier-general of volunteers, and for his skill in seizing certain important strategic points was on the 11th of April 1862 made major-general. He died of yellow fever at Beaufort, South Carolina, on the 30th of October 1862. He founded the *Sidereal Messenger* in 1846, was one of the first to adopt (in 1848) the electrical method of recording observations, and published besides other works, *The Orbs of Heaven* (1848, &c.), and *Popular Astronomy* (1860), both reissued at London in 1892.

See *Ormsby MacKnight Mitchel; a Biographical Narrative*, by his son, F. A. Mitchel (1887); P. C. Headley, *The Patriot Boy* (1865); *Amer. Journal of Science*, xxiv. 451 (1862); *Month. Notices Roy. Astr. Society*, xxiii. 133, xxxvii. 121 (C. Abbe); *Astr. Nach.*, No. 1401 (G. W. Hough).

MITCHELL, DONALD GRANT (1822–1908) American author, was born in Norwich, Connecticut, on the 12th of April 1822. He graduated at Yale College in 1841; studied law, but soon took up literature. Throughout his life he showed a particular interest in agriculture and landscape-gardening, which he followed at first in pursuit of health. He produced books of travel, volumes of essays on rural themes, of which *My Farm of Edgewood* (1863) is the best; sketchy studies of English monarchs and of English and American literature; and a character-novel entitled *Doctor Johns* (1866), &c.; but is best known as the author (under the pseudonym of "Ik Marvel"), of the sentimental essays contained in the volumes *Reveries of a Bachelor, or a Book of the Heart* (1850), and *Dream Life, a Fable of the Seasons* (1851).

MITCHELL, MARIA (1818–1889), American astronomer, was born of Quaker ancestry on the island of Nantucket on the 1st of August 1818. Her father, William Mitchell (1791–1869), was a school teacher and self-taught astronomer, who rated chronometers for Nantucket whalers, was an overseer of Harvard University (1857–1865), and for a time was employed by the United States Coast Survey. As early as 1831 (during the annular eclipse of the sun) she had been her father's assistant in his observations. On the 1st of October 1847 she discovered a telescopic comet (seen by De Vico Oct. 3, by W. R. Dawes Oct. 7, by Madame Rümker Oct. 11), and for this discovery she received a gold medal from the King of Denmark, and was elected (1848) to the American Academy of Arts and Sciences, and (1850) to the American Association for the Advancement of Science. In 1861 she removed from Nantucket to Lynn, where she used a large equatorial telescope presented to her by the women of America; and there she lived until 1865, when she became professor of astronomy and director of the observatory at Vassar College; in 1888 she became professor emeritus. In 1874 she began making photographs of the sun, and for years she made a special study of Jupiter and Saturn. She died at

Lynn on the 28th of June 1889. In 1908 an observatory was established in her honour at Nantucket.

See Phebe Mitchell Kendall, *Maria Mitchell: Life, Letters and Journals* (Boston, 1896); *In Memoriam* (Poughkeepsie, 1889), by her pupil and successor at Vassar, Mary W. Whitney; and a sketch by her brother, Henry Mitchell (1830–1902), himself a well-known hydrographer, in the *Proceedings* of the American Academy of Arts and Sciences, vol. xxv. (1889–1890), pp. 331–343.

MITCHELL, SILAS WEIR (1830—), American physician and author, son of a Philadelphia doctor, John Kearsley Mitchell (1798–1858), was born in Philadelphia on the 15th of February 1830. He studied at the university of Pennsylvania in that city, and received the degree of M.D. at Jefferson Medical College in 1850. During the Civil War he had charge of nervous injuries and maladies at Turner's Lane Hospital, Philadelphia, and at the close of the war became a specialist in nervous diseases. In this field Weir Mitchell's name became prominently associated with his introduction of the "rest cure," subsequently taken up by the medical world, for nervous diseases, particularly hysteria; the treatment consisting primarily in isolation, confinement to bed, dieting and massage. In 1863 he wrote a clever short story, combining physiological and psychological problems, entitled "The Case of George Dedlow," in the *Atlantic Monthly*. Thenceforward Dr Weir Mitchell, as a writer, divided his attention between professional and literary pursuits. In the former field he produced monographs on rattlesnake poison, on intellectual hygiene, on injuries to the nerves, on neurasthenia, on nervous diseases of women, on the effects of gunshot wounds upon the nervous system, and on the relations between nurse, physician, and patient; while in the latter he wrote juvenile stories, several volumes of respectable verse, and prose fiction of varying merit, which, however, gave him a leading place among the American authors of the close of the 19th century. His historical novels, *Hugh Wynne, Free Quaker* (1897), *The Adventures of François* (1898) and *The Red City* (1909), take high rank in this branch of fiction.

MITCHELL, SIR THOMAS LIVINGSTONE (1792–1855), Australian explorer, was born at Craigend, Stirlingshire, Scotland, on the 16th of June 1792. From 1808 to the end of the Peninsular War he served in Wellington's army, and was raised to the rank of major. He was appointed to survey the battlefields of the Peninsula, and his map of the Lower Pyrenees is still admired. In 1827 he was appointed deputy surveyor-general, and afterwards surveyor-general of New South Wales. He made four exploring expeditions between 1831 and 1846, and discovered the Peel, the Namoi, the Gwyder and other rivers, traced the course of the Darling and Glenelg, and was the first to penetrate into that portion of the country which he named Australia Felix. His last expedition was mainly devoted to the discovery of a route between Sydney and the Gulf of Carpentaria, and during the journey he explored the Fitzroy Downs, and discovered the Balonne, Victoria, Warrego and other streams. In 1838, while in England, Mitchell published his *Three Expeditions into the Interior of East Australia*. In 1839 he was knighted and made a D.C.L. of Oxford. During this visit he took with him some of the first specimens of gold and the first diamond found in Australia. In 1848 the narrative of his second expedition was published in London, *Journal of an Expedition into the Interior of Tropical Australia*. In 1851 he was sent to report on the Bathurst goldfields, and in 1853 he again visited England and patented his boomerang propeller for steamers. He died at Darling Point, Sydney, on the 5th of October 1855.

Besides the above works, Mitchell wrote a book on *Geographical and Military Surveying* (1827), an *Australian Geography*, and a translation of the *Lusiad* of Camoens. During his tenure of office as surveyor-general he published an admirable map (still in use) of the settled districts of New South Wales.

MITCHELL, a city and the county-seat of Davison county, South Dakota, U.S.A., about 70 m. W.N.W. of Sioux Falls. Pop. (1905), 5719; (1910), 6515. Mitchell is served by the Chicago, Milwaukee & St Paul and the Chicago, St Paul, Minneapolis & Omaha railways. Among its buildings and institutions are the city hall, the Federal building, a Carnegie library, a hospital, and a sanitorium. Mitchell is the seat of the Dakota Wesleyan University (1885; Methodist Episcopal). At Mitchell is a "corn palace," which is decorated each autumn with split ears of Indian corn, and is the centre of an annual festival, held in September and October. The city is an important shipping point for grain and livestock, and has a large wholesale trade. There are railway repair shops of the Chicago, Milwaukee & St Paul railway, machine shops, and manufactories of bricks and dressed lumber. Mitchell was settled in 1879 and chartered as a city in 1883.

MITCHELSTOWN, a market town of Co. Cork, Ireland, situated between the Kilworth and Galty Mountains, on a branch of the Great Southern & Western railway. Pop. (1901), 2146. Here is the Protestant Kingston College, a home for poor gentlefolk, founded by James, Lord Kingston, in 1760. The seat of the earls of Kingston was built in 1823. It is a massive castellated structure, among the finest of its kind in Ireland. The Mitchelstown limestone caves, exhibiting beautiful stalactite formations, are 6 m. distant in Co. Tipperary (*q.v.*). On the 9th of September 1887 Mitchelstown was the scene of a riot in connexion with the Irish Nationalist "plan of campaign." The police were compelled to fire on the rioters, and two men were killed, after which the coroner's jury brought in a verdict of wilful murder against the police. This verdict was ignored by the government, and subsequently quashed by the Queen's Bench in Dublin, but additional feeling was roused in respect of the incident owing to a message later sent by Mr Gladstone ending with the words "Remember Mitchelstown."

MITE, a name applied to an order of small Arachnida, with which this article deals, and to a coin of very slight value. The origin of both would appear to be ultimately the same, viz. a root *mei-*, implying something exceedingly small. It has been suggested that the name for the animal comes from a secondary root of the root *mei-*, to cut, whence come such words as Goth. *maitan*, to cut, and Ger. *messer*, knife. In this case mite would mean "the biter" or "cutter." The coin was originally a Flemish copper coin (Dutch *mijt*) worth one-third or, according to some authorities, a smaller fraction of the Flemish *penning*, penny. It has become a common expression in English for a coin of the smallest value, from its use to translate Gr. λεπτόν, two of which make a κοδράντης, translated "farthing" (Mark xii. 43).

In zoology, "mite" is the common name for minute members of the class Arachnida (*q.v.*), which, with the ticks, constitute the order Acari. The word "mite," however, is merely a popular and convenient term for certain groups of Acari, and does not connote a natural assemblage as contrasted with the ticks (*q.v.*). Mites are either free-living or parasitic throughout their lives or parasitic at certain periods and free-living at others. They are almost universally distributed, and are found wherever terrestrial vegetation, even of the lowliest kind, occurs. They are spread from the arctic to the antarctic hemisphere, and inhabit alike the land, fresh-water streams and ponds, brackish marshes and the sea. The largest species, which occur in the tropics, reach barely half an inch in length; while the smallest, the most diminutive of the Arthropoda, are invisible to the naked eye.

Mites are divided into a considerable number of families. The Bdellidae (*Bdella*) are free-living forms with long antenniform palpi. The large tropical forms above mentioned belong to the genus *Trombidium* of the family Trombidiidae. The members of this genus are covered with velvety plush-like hairs, often of an exquisite crimson colour. The legs are adapted for crawling or running, and the palpi are raptorial. They are non-parasitic in the adult stage; but immature individuals of a British species (*T. holosericeum*) are parasitic upon various animals (see HARVEST BUG). The Tetranychidae are nearly related to the last. A well-known example, *Tetranychus telarius*, spins webs on the backs of leaves, and is sometimes called the money spider. The fresh-water mites or Hydrachnidae are generally beautifully coloured red or green, and are commonly globular in shape. Their legs are furnished with long hairs for swimming. The marine mites of the family Halacaridae, on the contrary, are not active swimmers but merely creep on the stems of seaweeds and zoophytes. The Gamasidae are mostly free-living forms with a thick exoskeleton, and are allied to the Ixodidae or ticks (*q.v.*). A common species is *Gamasus coleoptratorum*, the females and young of which may be found upon the common dung-beetle. The Oribatidae or beetle-mites, so called from their resemblance to minute beetles, are non-parasitic, and often go through remarkable metamorphoses during development. The Sarcoptidae, as stated below, are mostly parasitic forms. Some members of this family, however, live in decaying animal substances, the best known perhaps being the cheese-mite (*Tyroglyphus siro*) which infests cheese, especially Stilton, in thousands. An allied species (*T. entomophagus*) often causes great damage to collections of insects by destroying the dried specimens. They may be easily exterminated by application of benzine, which does not harm the contents of the cabinet.

From the economic standpoint the most important mites are those which are parasitic upon mammals and birds. They belong to the four families, Gamasidae, Trombidiidae, Sarcoptidae and Demodicidae. Most of the Gamasidae are free-living mites. The family, however, contains an aberrant genus, *Dermanyssus*, of which several species have been described, although they are all perhaps merely varieties of one and the same species commonly known as *D. gallinae* or *D. avium*. This species is found in fowl-houses, dovecotes and bird-cages. During the day they lurk in cracks in the floor, walls or perches, and emerge at night to attack the roosting birds. They are a great pest, and frequently do much damage to birds both by sucking their blood and by depriving them of rest at night. They are sometimes transferred from birds to mammals. The Trombidiidae also are mostly free-living predaceous mites. A few, however, are parasitic upon mammals and birds, the best-known being *Trombidium holosericeum*, the larva of which attacks human beings, as well as chickens and other birds, sometimes producing considerable mortality amongst them (see HARVEST BUG). Another genus, *Cheyletiella*, affects rabbits as well as birds. Birds are also attacked by many species of Sarcoptidae, which according to the organs infected are termed plumicolae (Analgesinae), epidermicolae (Epidermoptinae), and cysticolae (Cytoditinae). The Analgesinae (*Pterolichus*, *Analges*) live almost wholly upon and between the barbules of the feathers. They are found in nearly every species of bird without apparently affecting the health in any way. The Epidermoptinae (*Epidermoptes*) occur on diseased fowls and live, as their name indicates, upon the skin at the base of the feathers, where their presence gives rise to an accumulation of yellowish scales. The Cytoditinae (*Cytodites*), on the other hand, live in the subcutaneous or intermuscular connective tissue round the respiratory organs, or in the air sacs, especially of gallinaceous species. They also penetrate to certain internal organs, and may become encysted and give rise to tubercle-like nodules. Sometimes they exist in such quantities in the air passages as to cause coughing and asphyxia.

The cutaneous mites, mentioned above, and others akin to them, produce no very marked disturbance in the skin of the species they infest. They merely suck the blood or feed upon the feathers, scurf and desquamating epidermis. Hence they are termed "non-psoric" mites. A certain number of species, however, called in contradistinction "psoric" mites, give rise by their bites, by the rapidity of their multiplication, and by the excavation of galleries in the skin, to a highly contagious disease known as scabies or mange, which if not treated in time produces the gravest results. These mites belong exclusively to the Sarcoptidae and Demodicidae. A variety of species are responsible for Sarcoptic mange, *Sarcoptes mutans* producing it in the feet of gallinaceous and passerine birds by burrowing beneath the scales and giving rise to a crusted exudation which pushes up beneath and between the scales. Feather scabies or depluming scabies of poultry is caused by another species, *S. laevis*. Three genera of Sarcoptidae, namely *Sarcoptes* *Chorioptes* and *Psoroptes* cause mange or scabies in mammals, the mange produced by *Sarcoptes* being the most serious form of the disease, because the females of the species which produces it, *Sarcoptes scabiei*, burrow beneath the skin and are more difficult to reach with acaricides. A considerable number of varieties of this species have been named after the hosts upon which they most commonly and typically occur, such as *S. scabiei hominis*, *equi*, *bovis*, *caprae*, *ovis*, *cameli*, *lupi*, *vulpis*, &c.; but they are not restricted to the mammals from which their names have been derived and structural differences between them are often difficult to define and sometimes non-existant. Under favourable conditions the multiplication of this species is very rapid. It has been computed indeed that a single pair may give rise to one million and a half individuals in about three months. *Psoroptes* lives in the epidermic incrustations to which it gives rise, without, however, excavating subcutaneous burrows. One species, *P. communis*, is known to affect various domestic animals. Of the genus *Chorioptes* two species have been described on domestic animals, viz. *Ch. symbiotes*, which has the same mode of life as *Psoroptes communis* and *Ch. cynotis*, which has been detected only in the ears of certain carnivora such as dogs, cats and ferrets. Mange, if taken in time, can be cured by applications of sulphur ointment or of sulphur mixed with an animal or vegetable oil. Mites of the family Demodicidae give rise to a skin disease called "Demodecic or follicular mange," which is often serious and always difficult to cure on account of the deep situation taken up by the parasites. These infest the hair follicles and sebaceous glands, and are therefore termed *Demodex folliculorum*. These mites differ greatly from those previously noticed—in the reduction of their legs to short three-jointed tubercles, and in the great elongation of the abdomen to form an annulated flexible postanal area to the body. They live not uncommonly in small numbers in the skin of the human face and their presence may never be detected. They also occur on dogs, pigs and other domesticated animals, as well as on mice and bats, and numerous varieties named after their hosts, *hominis*, *bavis*, *canis*, *cati*, &c., have been described, but they apparently differ from each other, principally in size.

The mites of the family Eriophyidae or Phytoptidae produce in various plants pathological results analogous to those produced in animals by parasitical Sarcoptidae and by Demodicidae. As in the Demodicidae the abdomen is elongate and annulate, but the Eriophyidae differ from all other mites in having permanently lost the last two pairs of legs. The excrescences and patches they produce on leaves are called "galls," the best known of which are perhaps the nail-galls of the lime caused by *Eriophyes tiliae*. A very large number of species have been described and named after the plants upon which they live. They often inflict very considerable loss upon fruit-growers by destroying the growing buds of the trees. (R. I. P.)

MITFORD, MARY RUSSELL (1787–1855), English novelist and dramatist, only daughter of Dr George Mitford, or Midford, was born at Alresford, Hampshire, on the 16th of December 1787. She retains an honourable place in English literature as the authoress of *Our Village*, a series of sketches of village scenes and characters unsurpassed in their kind, and as fresh as if they had been written yesterday. Her father was a curious character. He first spent his wife's fortune in a few years; then he spent the greater part of £20,000, which in 1797 his daughter, then at the age of ten, drew as a prize in a lottery; then he lived on a small remnant of his fortune and the proceeds of his daughter's literary industry. The father kept fresh in his daughter the keen delight in incongruities, the lively sympathy with self-willed vigorous individuality, and the womanly tolerance of its excess, which inspire so many of her sketches of character. Miss Mitford lived in close attendance on him, refused all holiday invitations because he could not live without her, and worked incessantly for him except when she broke off her work to read him the sporting newspapers. Her writing has all the charm of perfectly unaffected spontaneous humour, combined with quick wit and exquisite literary skill. Miss Mitford met Elizabeth Barrett (Mrs Browning) in 1836, and the acquaintance ripened into a warm friendship. The strain of poverty began to tell on her work, for although her books sold at high prices, her income did not keep pace with her father's extravagances. In 1837, however, she received a civil list pension, and five years later her father died. A subscription was raised to pay his debts, and the surplus increased the daughter's income. Miss Mitford eventually removed to a cottage at Swallowfield, near Reading, where she died on the 10th of January 1855.

Miss Mitford's youthful ambition had been to be "the greatest English poetess," and her first publications were poems in the manner of Coleridge and Scott (*Miscellaneous Verses*, 1810, reviewed by Scott in the *Quarterly*; *Christine*, a metrical tale, 1811; *Blanche*, 1813). Her play *Julian* was produced at Covent Garden, with Macready in the title-rôle, in 1823; *The Foscari* was performed at Covent Garden, with Charles Kemble as the hero, in 1826; *Rienzi*, 1828, the best of her plays, had a run of thirty-four nights, and Miss Mitford's friend, Talfourd, imagined that its vogue militated against the success of his own play *Ion*. *Charles the First* was refused a licence by the Lord Chamberlain, but was played at the Surrey Theatre in 1834. But the prose, to which she was driven by domestic necessities, has rarer qualities than her verse. The first series of *Our Village* sketches appeared in 1824, a second in 1826, a third in 1828, a fourth in 1830, a fifth in 1832. *Our Village* was several times reprinted; *Belford Regis*, a novel in which the neighbourhood and society of Reading were idealized, was published in 1835.

Her *Recollections of a Literary Life* (1852) is a series of *causeries* about her favourite books. Her talk was said by her friends, Mrs Browning and Hengist Horne, to have been even more amusing than her books, and five volumes of her *Life and Letters*, published in 1870 and 1872, show her to have been a delightful letter-writer.

MITFORD, WILLIAM (1744–1827), English historian, was the elder of the two sons of John Mitford, a barrister, who lived near Beaulieu, at the edge of the New Forest. Here, at Exbury House, his father's property, Mitford was born on the 10th of February 1744. He was educated at Cheam School, under the picturesque writer William Gilpin, but at the age of fifteen a severe illness led to his being removed, and after two years of idleness Mitford was sent, in July 1761, as a gentleman commoner to Queen's College, Oxford. In this year his father died, and left him the Exbury property and a considerable fortune. Mitford, therefore, being "very much his own master, was easily led to prefer amusement to study." He left Oxford (where the only sign of assiduity he had shown was to attend the lectures of Blackstone) without a degree, in 1763, and proceeded to the Middle Temple. But when he married Miss Fanny Molloy in 1766, and retired to Exbury for the rest of his life, he made the study of the Greek language and literature his hobby and occupation. After ten years his wife died, and in October 1776 Mitford went abroad. He was encouraged by French scholars whom he met in Paris, Avignon and Nice to give himself systematically to the study of Greek history. But it was Gibbon, with whom he was closely associated when they both were officers in the South Hampshire Militia, who suggested to Mitford the form which his work should take. In 1784 the first of the volumes of his *History of Greece* appeared, and the fifth and last of these quartos was published in 1810, after which the state of Mitford's eyesight and other physical infirmities, including a loss of memory, forbade his continuation of the enterprise, although he painfully revised successive new editions. While his book was progressing, Mitford was a member of the House of Commons, with intervals, from 1785 to 1818, and he was for many years verderer of the New Forest and a county magistrate; but it does not appear that he ever visited Greece. After a long illness, he died at Exbury on the 10th of February 1827. In addition to his *History of Greece*, he published a few smaller works, the most important of which was an *Essay on the Harmony of Language*, 1774. The style of Mitford is natural and lucid, but without the rich colour of Gibbon. He affected some oddities both of language and of orthography, for which he was censured and which he endeavoured to revise. But his political opinions were still more severely treated, since Mitford was an impassioned anti-Jacobin, and his partiality for a monarchy led him to be unjust to the Athenians. Hence his *History of Greece*, after having had no peer in European literature for half a century, faded in interest on the appearance of the work of Grote. Clinton, too, in his *Fasti hellenici*, charged Mitford with "a general negligence of dates," though admitting that in his philosophical range "he is far superior to any former writer" on Greek history. Byron, who dilated on Mitford's shortcomings, nevertheless declared that he was "perhaps the best of all modern historians altogether." This Mitford certainly is not, but his pre-eminence in the little school of English historians who succeeded Hume and Gibbon it would be easier to maintain.

William Mitford's cousin, the Rev. John Mitford (1781–1859), was editor of the *Gentleman's Magazine* and of various editions of the English poets. For the Freeman-Mitfords, who were also relatives, see REDESDALE, EARL OF.

MITHILA, an ancient kingdom of India, corresponding to that portion of Behar lying N. of the Ganges, with an extension into Nepal, where was the capital of Janakpur. Its early history is obscure, but it has always been noted for its peculiar conservatism and the learning of its Brahmans. They form to this day one of the five classes of northern Brahmans, and their head is the Maharaja of Darbhanga. The language, known as Maithili, is a dialect of Bihari, with an archaic system of grammar and a literature of its own.

MITHRADATES, less correctly MITHRIDATES, a Persian name derived from Mithras (*q.v.*), the sun-god, and the Indo-European root *da*, "to give," *i.e.* "given by Mithras." The name occurs also in the forms Mitradates (Herod. i. 110) and Meherdates (Tac. *Ann.* xii. 10). It was borne by a large number of Oriental kings, soldiers and statesmen. The earliest are Mithradates, the eunuch who helped Artabanus to assassinate Xerxes I. (Diod. xi. 69), and the Mithradates who fought first with Cyrus the Younger and after his death with Artaxerxes against the Greeks (Xen. *Anab.* ii. 5, 35; iii. 3, 1–10; iii. 4, 1–5), and is the ancestor of the kings of Pontus. The most important are three kings of Parthia of the Arsacid dynasty, and six (or four) kings of Pontus. There were also two kings of Commagene, two of the Bosporus and one of Armenia (A.D. 35–51).

MITHRADATES I. (Arsaces VI.), successor of his brother, Phraates I., came to the Parthian throne about 175 B.C. The first event of his reign was a war with Eucratides of Bactria, who tried to create a great Greek empire in the East. At last, when Eucratides had been murdered by his son about 150, Mithradates was able to occupy some districts on the border of Bactria and to conquer Arachosia (Kandahar); he is even said to have crossed the Indus (Justin 41, 6; Strabo xi. 515, 517; cf. Orosius v. 4, 16; Diod. 33, 18). Meanwhile the Seleucid kingdom was torn by internal dissensions, fostered by Roman intrigues. Phraates I. had already conquered eastern Media, about Rhagae (Rai), and subjected the Mardi on the border of the Caspian (Justin 41, 5; Isidor. *Charac.* 7). Mithradates I. conquered the rest of Media and advanced towards the Zagros chains and the Babylonian plain. In a war against the Elymaeans (in Susiana) he took the Greek town Seleucia on the Hedyphon, and forced their king to become a vassal of the Parthians (Justin 41, 6; Strabo xv. 744). About 141 he must have become master of Babylonia. By Diodorus 33, 18 he is praised as a mild ruler; and the fact that from 140 he takes on his coins the epithet *Philhellen* (W. Wroth, *Catalogue of the Coins of Parthia*, p. 14 seq.; till then he only calls himself "the great king Arsakes") shows that he tried to conciliate his Greek subjects. The Greeks, however, induced Demetrius II. Nicator to come to their deliverance, although he was much pressed in Syria by the pretender Diodotus Tryphon. At first he was victorious, but in 138 he was defeated. Mithradates settled him with a royal household in Hyrcania and gave him his daughter Rhodogune in marriage (Justin 36, 1, 38, 9; Jos. *Ant.* 13, 5, 11; Euseb. *Chron.* I. 257; Appian *Syr.* 67). Shortly afterwards Mithradates I. died, and was succeeded by his son Phraates II. He was the real founder of the Arsacid Empire.

Kings of Parthia.

MITHRADATES II. the Great, king of Parthia (*c.* 120–88 B.C.), saved the kingdom from the Mongolian Sacae (Tochari), who had occupied Bactria and eastern Iran, and is said to have extended the limits of the empire (Justin 42, 2, where he is afterwards confused with Mithradates III.). He defeated King Artavasdes of Armenia and conquered seventy valleys; and the prince Tigranes came as hostage to the Parthians (Justin 42, 2; Strabo, xi. 532). In an inscription from Delos (Dittenberger, *Or. gr. inscr.* 430) he is called "the great King of Kings Arsakes." He also interfered in the wars of the dynasts of Syria (Jos. *Ant.* xiii. 14, 3). He was the first Parthian king who entered into negotiations with Rome, then represented by Sulla, praetor of Cilicia (92 B.C.).

Mithradates III. murdered his father Phraates III. about 57 B.C., with the assistance of his brother Orodes. He was made king of Media, and waged war against his brother, but was soon deposed on account of his cruelty. He took refuge with Gabinius, the Roman proconsul of Syria. He advanced into Mesopotamia, but was beaten at Seleucia by Surenas, fled into Babylon, and after a long siege was taken prisoner and killed in 54 by Orodes I. (Dio Cass. 39, 56; Justin 42, 4; Jos. *Bell.* i. 8, 7, *Ant.* 14, 6, 4).

A Parthian king Mithradates, who must have occupied the throne for a short time during the reign of Phraates IV., is mentioned by Jos. *Ant.* xvi. 8, 4, in 10 B.C.; another pretender Meherdates was brought from Rome in A.D. 49 by the opponents of Gotarzes, but defeated (Tac. *Ann.* xi. 10, xii. 10 sqq.). The name of another pretender Mithradates (often called Mithradates IV.) occurs on a coin of the first half of the 2nd century, written in Aramaic, accompanied by the Arsacid titles in Greek (Wroth, *Catal. of the Coins of Parthia*, p. 219); he appears to be identical with Meherdotes, one of the rival kings of Parthia who fought against Trajan in 116; he died in an attack on Commagene and appointed his son Sanatruces successor, who fell in a battle against the Romans (Arrian *ap.* Malalas, *Chron.* pp. 270. 274). (Ed. M.)

Kings of Pontus.

The kings of Pontus were descended from one of the seven Persian conspirators who put the false Smerdis to death (see Darius I.). According to Diodorus Siculus, three members of his family—Mithradates, Ariobarzanes, Mithradates—were successively rulers of Cius on the Propontis and Carinē in Mysia. The last of these was put to death in 302 B.C. by Antigonus, who suspected him of having joined the coalition against him. He was succeeded by his son Mithradates I. or III. (if the two dynasts of Cius be included[1]) the founder (κτίστης) of the Pontic kingdom, although this distinction is by some attributed to the father. Warned by his friend Demetrius, the son of Antigonus, that he was threatened with the same fate as his father, he fled to Paphlagonia, where he seized Cimiata, a fort at the foot of the Olgassys range. Being joined by the Macedonian garrison and the neighbouring populations, he conquered the Cappadocian and Paphlagonian territories on both sides of the Halys and assumed the title of king. Before his death he further enlarged Pontic Cappadocia. He was succeeded by Ariobarzanes, who left the throne to Mithradates II. (*c.* 256–190, according to Meyer, *Mithradates II. and III.*), a mere child. Early in his reign the Gauls of Galatia invaded his territory. Mithradates was at the battle of Ancyra (*c.* 241), in which he assisted Antiochus Hierax against his brother Seleucus Callinicus, in spite of the fact that he had married the daughter of the latter with Greater Phrygia as her dowry. His two daughters, both named Laodice, were married, one to Antiochus the Great, the other to his cousin Achaeus, a dynast of Asia Minor. He unsuccessfully attacked Sinope, which was taken by his successor Pharnaces, the brother (not the son) of Mithradates III. (169–121), surnamed *Philopator*, *Philadelphus*, and *Euergetes*. According to Meyer, however, there were two kings (Mithradates IV. *Philopator* and V. *Euergetes*). He was the first king of Pontus to recognize the suzerainty of the Romans, of whom he was a loyal ally. He assisted Attalus II. of Pergamum to resist Prusias II. of Bithynia; furnished a contingent during the Third Punic War; and aided the Romans in obtaining possession of Pergamum, bequeathed to them by Attalus III., but claimed by Aristonicus, a natural son of Eumenes II. Both Mithradates and Nicomedes of Bithynia demanded Greater Phrygia in return for their services. It was awarded to Mithradates, but the senate refused to ratify the bargain on the ground of bribery. For several years the kings of Pontus and Bithynia bid against each other, till in 116 Phrygia was declared independent, although in reality it was treated as part of the province of Asia. Mithradates appears to have taken it without waiting for the decision of the senate. He invaded Cappadocia, and married his daughter to the young king, Ariarathes Epiphanes; bought the succession from the last king of Paphlagonia, and obtained a kind of protectorate over Galatia. He was a great admirer of the Greeks, who called him Euergetes; he removed his capital from Amasia to Sinope, and bestowed liberal gifts upon the temples of Delos and Athens. At the height of his power he was assassinated by his courtiers during a banquet in his palace at Sinope.

Mithradates VI. *Eupator*, called the Great, a boy of eleven, now succeeded his father. Alarmed at the attempts made upon his life by his mother, he fled to the mountains and was for many years a hunter. In 111 he returned to Sinope, threw his mother into prison, and put his younger brother to death. Having thus established himself on the throne, he turned his attention to conquest. In return for his assistance against the Scythians, the Greeks of the Cimmerian Bosporus and the Tauric Chersonese recognized his suzerainty. He occupied Colchis, Paphlagonia and part of Galatia; set his son Ariarathes on the throne of Cappadocia and drove out Nicomedes III., the young king of Bithynia. The Romans restored the legitimate kings, and, while apparently acquiescing, Mithradates made preparations for war. He had long hated the Romans, who had taken Phrygia during his minority, and he aimed at driving them from Asia Minor. The cause of rupture was the attack on Pontic territory by Nicomedes at the instigation of the Romans. Mithradates, unable to obtain satisfaction, declared war (88 B.C.). He rapidly overran Galatia, Phrygia and Asia, defeated the Roman armies, and ordered a general massacre of the Romans in Asia. He sent large armies into European Greece, and his generals occupied Athens. But Sulla in Greece and Fimbria in Asia defeated his armies in several battles; the Greek cities were disgusted by his severity, and in 84 he concluded peace, abandoning all his conquests, surrendering his fleet and paying a fine of 2000 talents. During what is called the Second Mithradatic War, Murena invaded Pontus without any good reason in 83, but was defeated in 82. Hostilities were suspended, but disputes constantly occurred, and in 74 a general war broke out. Mithradates defeated Cotta, the Roman consul, at Chalcedon; but Lucullus worsted him, and drove him in 72 to take refuge in Armenia with his son-in-law Tigranes. After two great victories at Tigranocerta (69) and Artaxata (68), Lucullus was disconcerted by mutiny and the defeat of his lieutenant Fabius (see Lucullus). In 66 he was superseded by Pompey, who completely defeated both Mithradates and Tigranes. The former established himself in 64 at Panticapaeum, and was planning new campaigns against the Romans when his own troops revolted, and, after vainly trying to poison himself, he ordered a Gallic mercenary to kill him. So perished the greatest enemy that the Romans had to encounter in Asia Minor. His body was sent to Pompey, who buried it in the royal sepulchre at Sinope.

Ancient authorities have invested Mithradates with a halo of romance. His courage, his bodily strength and size, his skill in the use of weapons, in riding, and in the chase, his speed of foot, his capacity for eating and drinking, his penetrating intellect and his mastery of 22 languages are celebrated to a degree which is almost incredible. With a surface gloss of Greek education, he united the subtlety, the superstition, and the obstinate endurance of an Oriental. He collected curiosities and works of art; he assembled Greek men of letters round him; he gave prizes to the greatest poets and the best eaters. He spent much of his time in practising magic, and it was believed that he had so saturated his body with poisons that none could injure him. He trusted no one; he murdered his mother, his sons, the sister whom he had married; to prevent his harem from falling to his enemies he murdered all his concubines, and his most faithful followers were never safe. For eighteen years he showed himself no unworthy adversary of Sulla, Lucullus and Pompey.

---

[1] There is much difference of opinion in regard to the kings of Pontus called Mithradates to the accession of Mithradates Eupator. Ed. Meyer reckons five, T. Reinach three.

See T. Reinach, *Mithridate Eupator* (1890; Ger. trans. by A. Goetz, 1895, with the author's corrections and additions); also E. Meyer, *Geschichte des Königreichs Pontos* (1879).

MITHRAS, a Persian god of light, whose worship, the latest one of importance to be brought from the Orient to Rome, spread throughout the empire and became the greatest antagonist of Christianity.

I. *History and Distribution.*—The cult goes back to a period before the separation of the Persians from the Hindus, as is shown by references in the literatures of both stocks, the Avesta and the Vedas. Though but faintly pictured in the Vedic hymns, he is there invoked with Ormazd, or Ahuramazda, the god of the sky, and is clearly a divinity of light, the protector of truth and the enemy of error and falsehood. In the Avesta, after the separation of the Iranian stock from the Hindu and the rise of Zoroastrianism, which elevated Ormazd to the summit of the Persian theological system, his rôle was more distinct, though less important; between Ormazd, who reigned in eternal brightness, and Ahriman, whose realm was eternal darkness, he occupied an intermediate position as the greatest of the *yazatas*, beings created by Ormazd to aid in the destruction of evil and the administration of the world. He was thus a deity of the realms of air and light, and, by transfer to the moral realm, the god of truth and loyalty. Because light is accompanied by heat, he was the god of vegetation and increase; he sent prosperity to the good, and annihilated the bad; he was the god of armies and the champion of heroes; as the enemy of darkness and of all evil spirits, he protected souls, accompanying them on the way to paradise, and was thus a redeemer. Animals and birds were sacrificed and libations poured to him, and prayers were addressed to him by devotees who had purified themselves by ablution and repeated flagellation. As a god who gave victory, he was prominent in the official cult of Persia, the seventh month and the sixteenth day of other months being sacred to him. His worship spread with the empire of the Persians throughout Asia Minor, and Babylon was an important centre. Its popularity remained unimpaired after the fall of Persia, and it was during the ferment following the conquests of Alexander that the characteristics which mark it during the Roman period were firmly fixed. Mithraism was at full maturity on its arrival at Rome, the only modifications it ever suffered having been experienced during its younger days in Asia.

Modified though never essentially changed, (1) by contact with the star-worship of the Chaldaeans, who identified Mithras with Shamash, god of the sun,(2) by the indigenous Armenian religion and other local Asiatic faiths and (3) by the Greeks of Asia Minor, who identified Mithras with Helios, and contributed to the success of his cult by equipping it for the first time with artistic representations (the famous Mithras relief originated in the Pergamene school towards the 2nd century B.C.), Mithraism was first transmitted to the Roman world during the 1st century B.C. by the Cilician pirates captured by Pompey. It attained no importance, however, for nearly two centuries. The lateness of its arrival in the West was due to the fact that its centres of influence were not in immediate contact with Greek and Roman civilization. It never became popular in Greek lands, and was regarded by Hellenized nations as a barbarous worship. It was at rivalry with the Egyptian religion. As late as the time of Augustus it was but little known in Roman territory, and gained a firm foothold in Italy only gradually, as a result of the intercourse between Rome and Asia consequent upon the erection of the Eastern provinces and the submission and colonization of Mesopotamia. It seems at first to have had relations with the cult of the Great Mother of the Gods at Rome, whose influence served to protect it and facilitate its growth. The cult of Mithras began to attract attention at Rome about the end of the 1st century A.D. Statius (*c.* A.D. 80) mentions the typical Mithraic relief in his *Thebaid* (i. 719,720); from Plutarch's (A.D. 46–125) *Vita Pompei* (24) it is apparent that the worship was well known; and the first Roman reliefs show the characteristics of about the same time.

Towards the close of the 2nd century the cult had begun to spread rapidly through the army, the mercantile class, slaves and actual propagandists, all of which classes were largely composed of Asiatics. It throve especially among military posts, and in the track of trade, where its monuments have been discovered in greatest abundance. The German frontiers afford most evidence of its prosperity. Rome itself was a favourite seat of the religion. From the end of the 2nd century the emperors encouraged Mithraism, because of the support which it afforded to the divine right of monarchs. The Persian belief that the legitimate sovereign reigned by the grace of Ormazd, whose favour was made manifest by the sending of the *Hvarenō*, a kind of celestial aureole of fire, resulted in the doctrine that the sun was the giver of the *Hvarenō*. Mithras, identified with Sol Invictus at Rome, thus became the giver of authority and victory to the imperial house. From the time of Commodus, who participated in its mysteries, its supporters were to be found in all classes. Its importance at Rome may be judged from the abundance of monumental remains—more than 75 pieces of sculpture, 100 inscriptions, and ruins of temples and chapels in all parts of the city and suburbs.

Finally, philosophy as well as politics contributed to the success of Mithraism, for the outcome of the attempt to recognize in the Graeco-Roman gods only forces of nature was to make the Sun the most important of deities; and it was the Sun with whom Mithras was identified.

The beginning of the downfall of Mithraism dates from A.D. 275, when Dacia was lost to the empire, and the invasions of the northern peoples resulted in the destruction of temples along a great stretch of frontier, the natural stronghold of the cult. The aggression of Christianity also was now more effective. The emperors, however, favoured the cult, which was the army's favourite until Constantine destroyed its hopes. The reign of Julian and the usurpation of Eugenius renewed the hopes of its devotees, but the victory of Theodosius (394) may be considered the end of its existence. It still survived in certain cantons of the Alps in the 5th century, and clung to life with more tenacity in its Eastern home. Its legitimate successor was Manichaeism, which afforded a refuge to those mystics who had been shaken in faith, but not converted, by the polemics of the Church against their religion.

II. *Sources, Remains, Ritual.*—The sources of present knowledge regarding Mithraism consist of the Vedas, the Avesta, the Pahlevi writings, Greek and Latin literature and inscriptions, and the cult monuments. The monuments comprise the remains of nearly a score of temples and about 400 statues and bas reliefs. The Mithraic temples of Roman times were artificial grottoes (*spelaea*) wholly or partially underground, in imitation of the original selcuded mountain caverns of Asia. The Mithraeum hewn in the tufa quarries of the Capitoline Hill at Rome, still in existence during the Renaissance, is an example. The main room of the ordinary temple was rectangular, with an elevated apsidal arrangement, like a choir, containing the sacred relief on its wall, at the end opposite the entrance, and with continuous benches (*podia*) of masonry, about 5 ft. wide and inclining slightly towards the floor, built against the wall on its long sides. The ceiling was made to symbolize the firmament. There were arrangements for the brilliant illumination of the choir and its relief, which was sometimes sculptured on both sides and reversible, while the *podia* were intentionally more obscure. The choir and the long space between the *podia* were for ministrants, the *podia* themselves for kneeling worshippers. Two altars, to the Sun and the Moon, stood before the former, and cult statues along the latter. The approach to the grotto lay through a portico on the level with and fronting the street, and a *pronaos*, in communication with which was a kind of sacristy. Steps led to the lower level of the sanctuary. The simplicity and smallness of the Mithraic temples are to be accounted for by structural and financial reasons; an underground temple was difficult to construct on a large scale, and the worshippers of Mithras were usually from the humbler classes. The average grotto held from fifty to a hundred persons. The size of the sanctuaries, however, was compensated for by their number; in Ostia alone there were five.

The typical bas relief, which is found in great abundance in the museums of Europe, invariably represents Mithras, under the form of a youth with conical cap and flying drapery, slaying the sacred bull, the scorpion attacking the genitals of the animal, the serpent drinking its blood, the dog springing towards the wound in its side, and frequently, in addition, the Sun-god, his messenger the raven, a fig-tree, a lion, a ewer, and torch-bearers. The relief is in some instances enclosed in a frame of figures and scenes in relief. The best example is the monument of Osterburken (Cumont, *Textes et monuments figurés*, No. 246). With this monument as a basis, Franz Cumont has arranged the small Mithraic reliefs into two groups, one illustrating the legend of the origin of the gods, and the other the legend of Mithras. In the first group are found Infinite Time, or Cronus; Tellus and Atlas supporting the globe, representing the union of Earth and Heaven; Oceanus; the Fates; Infinite Time giving into the hand of his successor Ormazd the thunderbolt, the symbol of authority; Ormazd struggling with a giant of evil—the Mithraic gigantomachy. The second group represents, first, the birth of Mithras; then the god nude, cutting fruit and leaves from a fig-tree in which is the bust of a deity, and before which one of the winds is blowing upon Mithras; the god discharging an arrow against a rock from which springs a fountain whose water a figure is kneeling to receive in his palms; the bull in a small boat, near which again occurs the figure of the animal under a roof about to be set on fire by two figures; the bull in flight, with Mithras in pursuit; Mithras bearing the bull on his shoulders; Helios kneeling before Mithras; Helios and Mithras clasping hands over an altar; Mithras with drawn bow on a running horse; Mithras and Helios banqueting; Mithras and Helios mounting the chariot of the latter and rising in full course over the ocean. Few of the Mithraic reliefs are of even mediocre art. Among the best is the relief from the Capitoline grotto, now in the Louvre.

Cumont's interpretation of the main relief and its smaller companions involves the reconstruction of a Mithraic theology, a Mithraic legend, and a Mithraic symbolism. Paucity of evidence makes the first difficult. The head of the divine hierarchy of Mithras was Infinite Time—Cronus, Saturn; Heaven and Earth were his offspring, and begat Ocean, who formed with them a trinity corresponding to Jupiter, Juno, and Neptune. From Heaven and Earth sprang the remaining members of a circle analogous to the Olympic gods. Ahriman, also the son of Time, was the Persian Pluto. Owing to Semitic influence every Persian god had in Roman times come to possess a twofold significance—astrological and natural, Semitic and Iranian—the earlier and deeper Iranian significance being imparted by the clergy to the few intelligent elect, the more attractive and superficial Chaldaean symbolism being presented to the multitude. Mithras was the most important member of the circle. He was regarded as the mediator between suffering humanity and the unknowable and inaccessible god of all being, who reigned in the ether.

The Mithras legend has been lost, and can be reconstructed only from the scenes on the above described relief. Mithras was born of a rock, the marvel being seen only by certain shepherds, who brought gifts and adored him. Chilled by the wind, the new-born god went to a fig-tree, partook of its fruit, and clothed himself in its leaves. He then undertook to vanquish the beings already in the world, and rendered subject to him first the Sun, with whom he concluded a treaty of friendship. The most wonderful of his adventures, however, was that with the sacred bull which had been created by Ormazd. The hero seized it by the horns and was borne headlong in the flight of the animal, which he finally subdued and dragged into a cavern. The bull escaped, but was overtaken, and by order of the Sun, who sent his messenger the raven, was reluctantly sacrificed by Mithras. From the dying animal sprang the life of the earth, although Ahriman sent his emissaries to prevent it. The soul of the bull rose to the celestial spheres and became the guardian of herds and flocks under the name of Silvanus. Mithras was through his deed the creator of life. Meanwhile Ahriman sent a terrible drought upon the land. Mithras defeated his purpose by discharging an arrow against a rock and miraculously drawing the water from it. Next Ahriman sent a deluge, from which one man escaped in a boat with his cattle. Finally a fire desolated the earth, and only the creatures of Ormazd escaped. Mithras, his work accomplished, banqueted with the Sun for the last time, and was taken by him in his chariot to the habitation of the immortals, whence he continued to protect the faithful.

The symbolism employed by Mithraism finds its best illustration in the large central relief, which represents Mithras in the act of slaying the bull as a sacrifice to bring about terrestrial life, and thus portrays the concluding scenes in the legend of the sacred animal. The scorpion, attacking the genitals of the bull, is sent by Ahriman from the lower world to defeat the purpose of the sacrifice; the dog, springing towards the wound in the bull's side, was venerated by the Persians as the companion of Mithras; the serpent is the symbol of the earth being made fertile by drinking the blood of the sacrificial bull; the raven, towards which Mithras turns his face as if for direction, is the herald of the Sun-god, whose bust is near by, and who has ordered the sacrifice; various plants near the bull, and heads of wheat springing from his tail, symbolize the result of the sacrifice; the cypress is perhaps the tree of immortality. There was also an astrological symbolism, but it was superficial, and of secondary importance. The torch-bearers sometimes seen on the relief represent one being in three aspects—the morning, noon and evening sun, or the vernal, summer and autumn sun.

Owing to the almost absolute disappearance of documentary evidence, it is impossible to know otherwise than very imperfectly the inner life of Mithraism. Jerome (*Epist.* cvii.) and inscriptions preserve the knowledge that the mystic, *sacratus*, passed through seven degrees, which probably corresponded to the seven planetary spheres traversed by the soul in its progress to wisdom, perfect purity, and the abode of the blest: *Corax*, Raven, so named because the raven in Mithraic mythology was the servant of the Sun; *Cryphius*, Occult, a degree in the taking of which the mystic was perhaps hidden from others in the sanctuary by a veil, the removal of which was a solemn ceremonial; *Miles*, Soldier, signifying the holy warfare against evil in the service of the god; *Leo*, Lion, symbolic of the element of fire; *Perses*, Persian, clad in Asiatic costume, a reminiscence of the ancient origin of the religion; *Heliodromus*, Courier of the Sun, with whom Mithras was identified; *Pater*, Father, a degree bringing the mystic among those who had the general direction of the cult for the rest of their lives. One relief (Cumont, vol. i. p. 175, fig. 10) shows figures masked and costumed to represent *Corax*, *Perses*, *Miles* and *Leo*, indicating the practice on occasion of rites involving the use of sacred disguise, a custom probably reminiscent of the primitive time when men represented their deities under the form of animals, and believed themselves in closer communion with them when disguised to impersonate them. Of the seven degrees, those mystics not yet beyond the third, *Miles*, were not in full communion, and were called ὑπηρετοῦντες (servants); while the fourth degree, *Leo*, admitted them into the class of the fully initiate, the μετέχοντες (participants). No women were in any way connected with the cult, though the male sex could be admitted even in childhood. The time requisite for the several degrees is unknown, and may have been determined by the *Patres*, who conferred them in a solemn ceremony called *Sacramentum*, in which the initial step was an oath never to divulge what should be revealed, and for which the mystic had been specially prepared by lustral purification, prolonged abstinence, and severe deprivations. Special ceremonies accompanied the diverse degrees: Tertullian speaks of "marking the forehead of a *Miles*," which may have been the branding of a Mithraic sign; honey was applied to the tongue and hands of the *Leo* and the *Perses*. A sacred communion of bread, water and possibly wine, compared by the Christian apologists to the Eucharist, was administered to the mystic who was entering upon one of the advanced degrees, perhaps *Leo*. The ceremony was probably commemorative of the banquet of Mithras and Helios before the former's ascension, and its effect strength of body, wisdom, prosperity, power to resist evil, and participation in the immortality enjoyed by the god himself. Other features reminiscent of the original barbarous rites in the primitive caverns of the East, no doubt also occupied a place in the cult; bandaging of eyes, binding of hands with the intestines of a fowl, leaping over a ditch filled with water, witnessing a simulated murder, are mentioned by the Pseudo-Augustine; and the manipulation of lights in the crypt, the administration of oaths, and the repetition of the sacred formulae, all contributed toward inducing a state of ecstatic exaltation. What in the opinion of Albrecht Dieterich (*Eine Mithrasliturgie*, Leipzig, 1903) is a Mithras liturgy is preserved in a Greek MS. of Egyptian origin of about A.D. 300. It is the ritual of a magician, imbedded in which, and alternating with magic formulae and other occult matter, are a number of invocations and prayers which Dieterich reconstructs as a liturgy in use by the clergy of Mithras between A.D. 100 and 300, and adapted to this new use about the latter date.

The Mithraic priest, *sacerdos* or *antistes*, was sometimes also of the degree of *pater*. Tertullian (*De praescr. haeret.* 40) calls the chief priest *summus pontifex*, probably the *pater patrum* who had general supervision of all the initiates in one city, and states that he could marry but once. According to the same author, there were Mithraic, as well as Christian, *virgines et continentes*. Besides the administration of sacraments and the celebration of offices on special occasions, the priest kept alight the eternal fire on the altar, addressed prayers to the Sun at dawn, midday and twilight, turning towards east, south and west respectively. Clad in Eastern paraphernalia, he officiated at the numerous sacrifices indicated by the remains of iron and bronze knives, hatchets, chains, ashes and bones of oxen, sheep, goats, swine, fowl, &c. There was pouring of libations, chanting and music, and bells and candles were employed in the service. Each day of the week was marked by the adoration of a special planet, the sun being the most sacred of all, and certain dates, perhaps the sixteenth of each month and the equinoxes, in conformity with the character of Mithras as mediator, were set aside for special festivals.

The Mithraic community of worshippers, besides being a spiritual fraternity, was a legal corporation enjoying the right of holding property, with temporal officials at its head, like any other *sodalitas*: there were the *decuriones* and *decem primi*, governing councils resembling assembly and senate in cities; *magistri*, annually elected presidents; *curatores*, financial agents; *defensores*, advocates; and *patroni*, protectors among the influential. It may be that a single temple was the resort of several small associations of worshippers which were subdivisions of the whole community. The cult was supported mainly by voluntary contribution. An abundance of epigraphic evidence testifies to the devotion of rich and poor alike.

III. *Moral Influence*.—The rapid advance of Mithraism was due to its human qualities. Its communities were bound together by a sense of close fraternal relation. Its democracy obliterated the distinctions between rich and poor; slave and senator became subject to the same rule, eligible for the same honours, partook of the same communion, and were interred in the same type of sepulchre, to await the same resurrection. The reward of title and degree and the consequent rise in the esteem of his fellows and himself was also a strong incentive; but the Mithraic faith itself was the greatest factor. The impressiveness and the stimulating power of the mystic ceremonies, the consciousness of being the privileged possessor of the secret wisdom of the ancients, the sense of purification from sin, and the expectation of a better life where there was to be compensation for the sufferings of this world—were all strong appeals to human nature. The necessity of moral rectitude was itself an incentive. Courage, watchfulness, striving for purity, were all necessary in the incessant combat with the forces of evil. Resistance to sensuality was one aspect of the struggle, and asceticism was not unknown. Mithras was ever on the side of the faithful, who were certain to triumph both in this world and the next. The worthy soul ascended to its former home in the skies by seven gates or degrees, while the unworthy soul descended to the realms of Ahriman. The doctrine of the immortality of the soul was accompanied by that of the resurrection of the flesh; the struggle between good and evil was one day to cease, and the divine bull was to appear on earth, Mithras was to descend to call all men from their tombs and to separate the good from the bad. The bull was to be sacrificed to Mithras, who was to mingle its fat with consecrated wine and give to drink of it to the just, rendering them immortal, while the unjust, together with Ahriman and his spirits, were to be destroyed by a fire sent from Heaven by Ormazd. The universe, renewed, was to enjoy eternal happiness.

IV. *Relation to Christianity*.—The most interesting aspect of Mithraism is its antagonism to Christianity. Both religions were of Oriental origin; they were propagated about the same time, and spread with equal rapidity on account of the same causes, viz. the unity of the political world and the debasement of its moral life. At the end of the 2nd century each had advanced to the farthest limits of the empire, though the one possessed greatest strength on the frontiers of the Teutonic countries, along the Danube and the Rhine, while the other throve especially in Asia and Africa. The points of collision were especially at Rome, in Africa, and in the Rhône Valley, and the struggle was the more obstinate because of the resemblances between the two religions, which were so numerous and so close as to be the subject of remark as early as the 2nd century, and the cause of mutual recrimination. The fraternal and democratic spirit of the first communities, and their humble origin; the identification of the object of adoration with light and the Sun; the legends of the shepherds with their gifts and adoration, the flood, and the ark; the representation in art of the fiery chariot, the drawing of water from the rock; the use of bell and candle, holy water and the communion; the sanctification of Sunday and of the 25th of December; the insistence on moral conduct, the emphasis placed upon abstinence and self-control; the doctrine of heaven and hell, of primitive revelation, of the mediation of the Logos emanating from the divine, the atoning sacrifice, the constant warfare between good and evil and the final triumph of the former, the immortality of the soul, the last judgment, the resurrection of the flesh and the fiery destruction of the universe—are some of the resemblances which, whether real or only apparent, enabled Mithraism to prolong its resistance to Christianity. At their root lay a common Eastern origin rather than any borrowing.

On the other hand, there were important contrasts between the two. Mithraism courted the favour of Roman paganism and combined monotheism with polytheism, while Christianity was uncompromising. The former as a consequence won large numbers of supporters who were drawn by the possibility it afforded of adopting an attractive faith which did not involve a rupture with the religion of Roman society, and consequently with the state. In the middle of the 3rd century Mithraism seemed on the verge of becoming the universal religion. Its eminence, however, was so largely based upon dalliance with Roman society, its weakness so great in having only a mythical character, instead of a personality, as an object of adoration, and in excluding women from its privileges, that it fell rapidly before the assaults of Christianity. Manichaeism, which combined the adoration of Zoroaster and Christ, became the refuge of those supporters of Mithraism who were inclined to compromise, while many found the transition to orthodox Christianity easy because of its very resemblance to their old faith.

See Franz Cumont, *Textes et monuments figurés relatifs aux mystères de Mithra* (Brussels, 1896, 1899), which has superseded all publications on the subject; Albrecht Dieterich, *Eine Mithrasliturgie* (Leipzig, 1903). See also the translation of Cumont's *Conclusions* (the second part of vol. i. of the above work, published separately 1902, under the title *Les Mystères de Mithra*), by T. J. McCormack (Chicago and London, 1903). Extended bibliography in Roscher's *Lexicon der Mythologie.* (G. Sn.)

MITRA, RAJENDRA LALA (1824–1891), Indian Orientalist, was born in a suburb of Calcutta on the 15th of February 1824, of a respectable family of the Kayasth or writer caste of Bengal. To a large extent he was self-educated, studying Sanskrit and Persian in the library of his father. In 1846 he was appointed librarian of the Asiatic Society, and to that society the remainder of his life was devoted—as philological secretary, as vice-president, and as the first native president in 1885. Apart from very numerous contributions to the society's journal, and to the series of Sanskrit texts entitled "Bibliotheca indica," he published three separate works: (1) *The Antiquities of Orissa* (2 vols., 1875 and 1880), illustrated with photographic plates, in which he traced back the image of Jagannath (Juggernaut) and also the car-festival to a Buddhistic origin; (2) a similarly illustrated work on *Bodh Gaya* (1878), the hermitage of Sakya Muni, and (3) *Indo-Aryans* (2 vols., 1881), a collection of essays dealing with the manners and customs of the people of India from Vedic times. He received the honorary degree of LL.D. from the university of Calcutta in 1875, the companionship of the Indian Empire when that order was founded in 1878, and the title of raja in 1888. He died at Calcutta on the 26th of July 1891.

MITRE (Lat. *mitra*, from Gr. *μίτρα*, a band, head-band, head-dress), a liturgical head-dress of the Catholic Church, generally proper to bishops.

1. *Latin Rite.*—In the Western Church its actual form is that of a sort of folding cap consisting of two halves which, when not worn, lie flat upon each other. These sides are stiffened, and when the mitre is worn, they rise in front and behind like two horns pointed at the tips (*cornua mitrae*). From the lower rim of the mitre at the back hang two bands (*infulae*), terminating in fringes. In the Roman Catholic Church mitres are divided into three classes: (1) *Mitra pretiosa*, decorated with jewels, gold plates, &c.; (2) *Mitra auriphrygiata*, of white silk, sometimes embroidered with gold and silver thread or small pearls, or of cloth of gold plain; (3) *Mitra simplex*, of white silk damask, silk or linen, with the two falling bands behind terminating in red fringes. Mitres are the distinctive head-dress of bishops; but the right to wear them, as in the case of the other episcopal insignia, is granted by the popes to other dignitaries—such as abbots or the heads and sometimes all the members of the chapters of cathedral or collegiate churches. In the case of these latter, however, the mitre is worn only in the church to which the privilege is attached and on certain high festivals. Bishops alone, including of course the pope and his cardinals, are entitled to wear the *pretiosa* and *auriphrygiata*; the others wear the *mitra simplex*.

The proper symbol of episcopacy is not so much the mitre as the ring and pastoral staff. It is only after the service of consecration and the mass are finished that the consecrating prelate asperses and blesses the mitre and places on the head of the newly consecrated bishop, according to the prayer which accompanies the act, "the helmet of protection and salvation," the two horns of which represent "the horns of the Old and New Testaments," a terror to "the enemies of truth," and also the horns of "divine brightness and truth" which God set on the brow of Moses on Mount Sinai. There is no suggestion of the popular idea that the mitre symbolizes the "tongues of fire" that descended on the heads of the apostles at Pentecost.

According to the Roman *Caeremoniale* the bishop wears the *mitra pretiosa* on high festivals, and always during the singing of the *Te Deum* and the *Gloria* at mass. He is allowed, however, "on account of its weight," to substitute for the *pretiosa* the *auriphrygiata* during part of the services, *i.e.* at Vespers from the first psalm to the *Magnificat*, at mass from the end of the *Kyrie* to the canon. The *auriphrygiata* is worn during Advent, and from Septuagesima to Maundy Thursday, except on the third Sunday in Advent (*Gaudete*), the fourth in Lent (*Laetare*) and on such greater festivals as fall within this time. It is worn, too, on the vigils of fasts, Ember Days and days of intercession, on the Feast of Holy Innocents (if on a week-day), at litanies, penitential processions, and at other than solemn benedictions and consecrations. At mass and vespers the *mitra simplex* may be substituted for it in the same way as the *auriphrygiata* for the *pretiosa*. The *simplex* is worn on Good Friday, and at masses for the dead; also at the blessing of the candles at Candlemas, the singing of the absolution at the coffin, and the solemn investiture with the pallium. At provincial synods archbishops wear the *pretiosa*, bishops the *auriphrygiata*, and mitred abbots the *simplex*. At general councils bishops wear white linen mitres, cardinals mitres of white silk damask; this is also the case when bishops and cardinals *in pontificalibus* assist at a solemn pontifical function presided over by the pope.

Lastly, the mitre, though a liturgical vestment, differs from the others in that it is never worn when the bishop addresses the Almighty in prayer—*e.g.* during mass he takes it off when he turns to the altar, placing it on his head again when he turns to address the people (see 1 Cor. xi. 4).

Origin and Antiquity.

The origin and antiquity of the episcopal mitre have been the subject of much debate. Some have claimed for it apostolical sanction and found its origin in the liturgical head-gear of the Jewish priesthood. Such proofs as have been adduced for this view are, however, based on the fallacy of reading into words (*mitra*, *infula*, &c.) used by early writers a special meaning which they only acquired later. *Mitra*, even as late as the 15th century, retained its simple meaning of cap (see Du Cange, *Glossarium*, *s.v.*); to Isidore of Seville it is specifically a woman's cap. *Infula*, which in late ecclesiastical usage was to be confined to mitre (and its dependent bands) and chasuble, meant originally a piece of cloth, or the sacred fillets used in pagan worship, and later on came to be used of any ecclesiastical vestment, and there is no evidence for its specific application to the liturgical head-dress earlier than the 12th century. With the episcopal mitre the Jewish *miznephet*, translated "mitre" in the Authorized Version (Exod. xxviii. 4, 36), has nothing to do, and there is no evidence for the use of the former before the middle of the 10th century even in Rome, and elsewhere than in Rome it does not make its appearance until the 11th.[1]

The first trustworthy notice of the use of the mitre is under Pope Leo IX. (1049–1054). This pope invested Archbishop Eberhard of Trier, who had accompanied him to Rome, with the Roman *mitra*, telling him that he and his successors should wear it *in ecclesiastico officio* (*i.e.* as a liturgical ornament) according to Roman custom, in order to remind him that he is a disciple of the Roman see (Jaffé, *Regesta pont. rom.*, ed. Leipzig, 1888, No. 4158). This proves that the use of the mitre had been for some time established at Rome; that it was specifically a Roman ornament; and that the right to wear it was only granted to ecclesiastics elsewhere as an exceptional honour.[2] On the other hand, the Roman *ordines* of the 8th and 9th centuries make no mention of the mitre; the evidence goes to prove that this liturgical head-dress was first adopted by the popes some time in the 10th century; and Father Braun shows convincingly that it was in its origin nothing else than the papal *regnum* or *phrygium* which, originally worn only at outdoor processions and the like, was introduced into the church, and thus developed into the liturgical mitre, while outside it preserved its original significance as the papal tiara (*q.v.*). From Leo IX.'s time papal grants of the mitre to eminent prelates became increasingly frequent, and by the 12th century it had been assumed by all bishops in the West, with or without papal sanction, as their proper liturgical head-dress. From the 12th century, too, dates the custom of investing the bishop with the mitre at his consecration.

---

[1] Father Braun, S. J., has dealt exhaustively with the supposed evidence for its earlier use—*e.g.* he proves conclusively that the *mitra* mentioned by Theodulph of Orleans (*Paraenes. ad episc.*) is the Jewish *miznephet*, and the well-known miniature of Gregory the Great (not St Dunstan, as commonly assumed) wearing a mitre (Cotton MSS. Claudius A. iii.) in the British Museum, often ascribed to the 10th or early 11th century, he judges from the form of the pallium and dalmatic to have been produced at the end of the 11th century "at earliest." The papal bulls granting the use of mitres before the 11th century are all forgeries (*Liturgische Gewandung*, 431–448).

[2] That it had been already so granted is proved by a miniature containing the earliest extant representations of a mitre, in the *Exultete rotula* and baptismal *rotula* at Bari (reproduced in Berteaux, *L'Art dans l'Italie méridionale*, I., Paris, 1904).

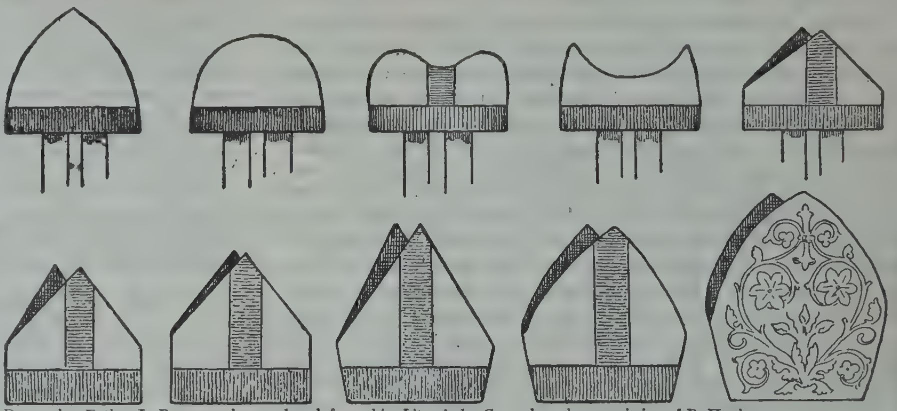
Non-bishops.

It was not till the 12th century that the mitre came to be regarded as specifically episcopal, and meanwhile the custom had grown up of granting it *honoris causa* to other dignitaries besides bishops. The first known instance of a mitred abbot is Egelsinus of St Augustine's, Canterbury, who received the honour from Pope Alexander II. in 1063. From this time onward papal bulls bestowing mitres, together with other episcopal *insignia*, on abbots become increasingly frequent. The original motive of the recipients of these favours was doubtless the taste of the time for outward display; St Bernard, zealous for the monastic ideal, denounced abbots for wearing mitres and the like *more pontificum*, and Peter the Cantor roundly called the abbatial mitre "inane, superfluous and puerile" (*Verb. abbrev.* c. xliv. in Migne, *Patrolog. lat.* 205, 159). It came, however, to symbolize the exemption of the abbots from episcopal jurisdiction, their quasi-episcopal character, and their immediate dependence on the Holy See. No such significance could attach to the grant of the *usus mitrae* (under somewhat narrow restrictions as to where and when) to cathedral dignitaries. The first instance is again a bull of Leo IX. (1051) granting to Hugh, archbishop of Besançon, and his seven cardinals the right to wear the mitre at the altar as celebrant, deacon and subdeacon, a similar privilege being granted to Bishop Hartwig of Bamberg in the following year. The intention was to show honour to a great church by allowing it to follow the custom doubtless already established at Rome. Subsequently the privilege was often granted, sometimes to one or more of the chief dignitaries, sometimes to all the canons of a cathedral (*e.g.* Campostella, Prague).

Mitres were also sometimes bestowed by the popes on secular sovereigns, *e.g.* by Nicholas II. (1058–1061) on Spiteneus (Spytihněw) II., duke of Bohemia; by Alexander II. on Wratislaus of Bohemia; by Lucius II. (1144–1145) on Roger of Sicily; and by Innocent III., in 1204, on Peter of Aragon. In the coronation of the emperor, more particularly, the mitre played a part. According to the 14th Roman *ordo*, of 1241, the pope places on the emperor's head first the *mitra clericalis*, then the imperial diadem. Father Braun (*Liturgische Gewandung*, p. 457) gives a picture of a seal of Charles IV. representing him as wearing both.

Development of Form.

The original form of the mitre was that of the early papal tiara (*regnum*), *i.e.* a somewhat high conical cap. The stages of its general development from this shape to the high double-horned modern mitre are clearly traceable (see fig. 1), though it is impossible exactly to distinguish them in point of date. The most characteristic modifications may be said to have taken place from the 11th to the middle of the 13th century. About 1100 the conical mitre begins to give place to a round one; a band of embroidery is next set over the top from back to front, which tends to bulge up the soft material on either side; and these bulges develop into points or horns. Mitres with horns on either side seem to have been worn till about the end of the 12th century, and Father Braun gives examples of their appearances on episcopal seals in France until far into the 13th. Such a mitre appears on a seal of Archbishop Thomas Becket (Father Thurston, *The Pallium*, London, 1892, p. 17). The custom was, however, already growing up of setting the horns over the front and back of the head instead of the sides (the mitre said to have belonged to St Thomas Becket, now at Westminster Cathedral, is of this type),[1] and with this the essential character of the mitre, as it persisted through the middle ages, was established. The exaggeration of the height of the mitre, which began at the time of the Renaissance, reached its climax in the 17th century. This ugly and undignified type is still usually worn in the Roman Catholic Church, but in some cases the earlier type has survived, and many bishops are also now reverting to it.



Drawn by Father J. Braun and reproduced from his *Liturgische Gewandung* by permission of B. Herder.

FIG. 1.—Evolution of the Mitre from the 11th century to the present day.

The decoration of mitres was characterized by increasing elaboration as time went on. From the first the white conical cap seems to have been decorated round the lower edge by a band or orphrey (*circulus*). To this was added later a vertical orphrey (*titulus*), usually from the centre of the front of the *circulus* to that of the back, partly in order to hide the seam, partly to emphasize the horns when those were to left and right. When the horns came to be set before and behind, the vertical orphrey retained its position. Of the surviving early mitres the greater number have only the orphrey embroidered, the body of the mitre being left plain. Very early, however, the custom arose of ornamenting the triangular spaces between the orphreys with embroidery, usually a round medallion, or a star, set in the middle, but sometimes figures of saints, &c. (*e.g.* the early example from the cathedral of Anagni, reproduced by Braun, p. 469). The richness and variety of decoration increased from the 14th century onwards. Architectural motives even were introduced, as frames to the embroidered figures of saints, while sometimes the upper edges of the mitre were ornamented with crockets, and the horns with architectural finials. Finally, the traditional *circulus* and *titulus* seem all but forgotten, the whole front and back surfaces of the mitre being ornamented with embroidered pictures or with arabesque patterns. The latter is characteristic of the mitre in the modern Roman Catholic Church, the tradition of the local Roman Church having always excluded the representation of figures on ecclesiastical vestments.

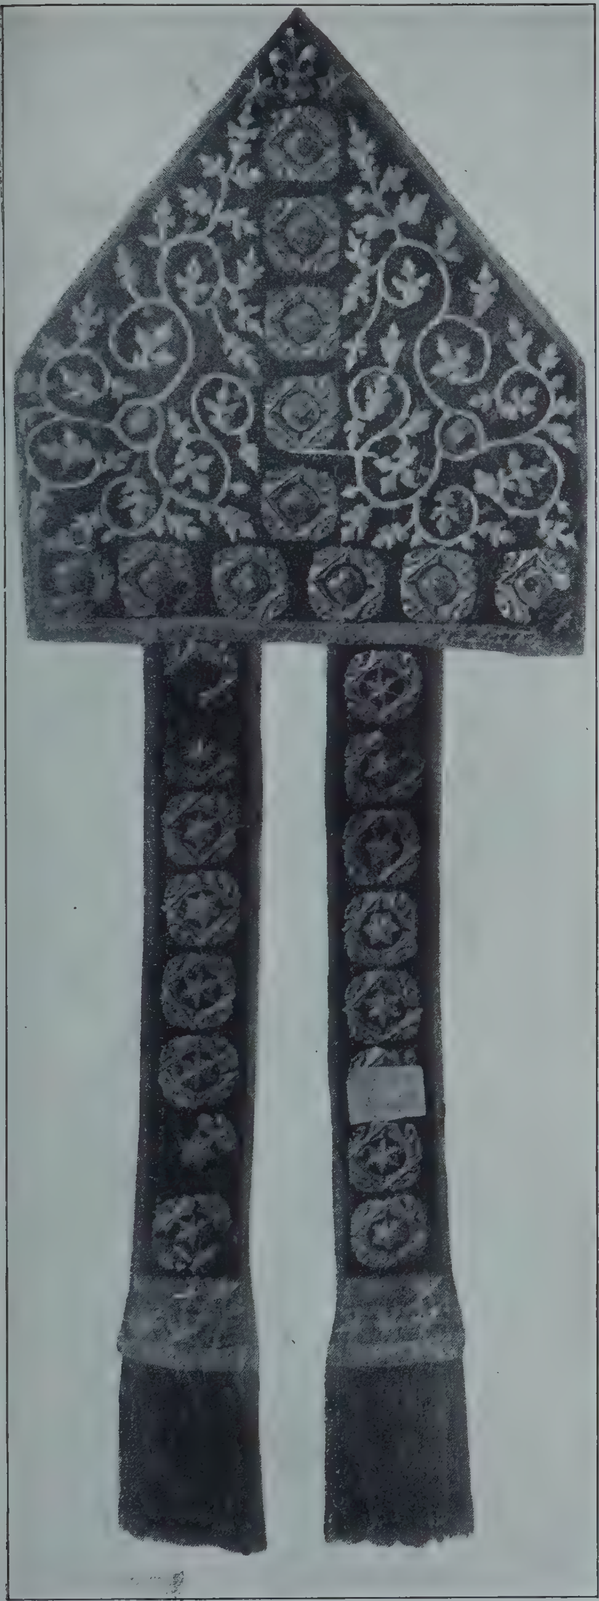
2. *Reformed Churches.*—In most of the reformed Churches the use of mitres was abandoned with that of the other vestments. They have continued to be worn, however, by the bishops of the Scandinavian Lutheran Churches.

Church of England.

In the Church of England the use of the mitre was discontinued at the Reformation. There is some evidence to show that it was used in consecrating bishops up to 1552, and also that its use was revived by the Laudian bishops in the 17th century (*Hierurgia anglicana* ii. 242, 243, 240). In general, however, there is no evidence to prove that this use was liturgical, though the silver-gilt mitre of Bishop Wren of Ely (d. 1667), which is preserved, is judged from the state of the lining to have been worn. The instances of the use of the mitre quoted in *Hier. anglic.* ii. 310, as carried by the bishop of Rochester at an investiture of the Knights of the Bath (1725), and by the archbishops and bishops at the coronation of George II. (1727), have no liturgical significance. The tradition of the mitre as an episcopal ornament has, nevertheless, been continuous in the Church of England, "and that on three lines: (1) heraldic usage; (2) its presence on the head of effigies of bishops, of which a number are extant, of the 16th, 17th, 18th and 19th centuries; (3) its presence in funeral processions, where

---

[1] In Father Braun's opinion, expressed to the writer, this mitre which was formerly at Sens, belongs probably to the 13th century.



From a photograph by Father Joseph Braun, S. J., by kind permission.

FIG. 5.—German Mitre, of red velvet embroidered with pearls and silver gilt plaques. 15th century. In the cathedral at Halberstadt.

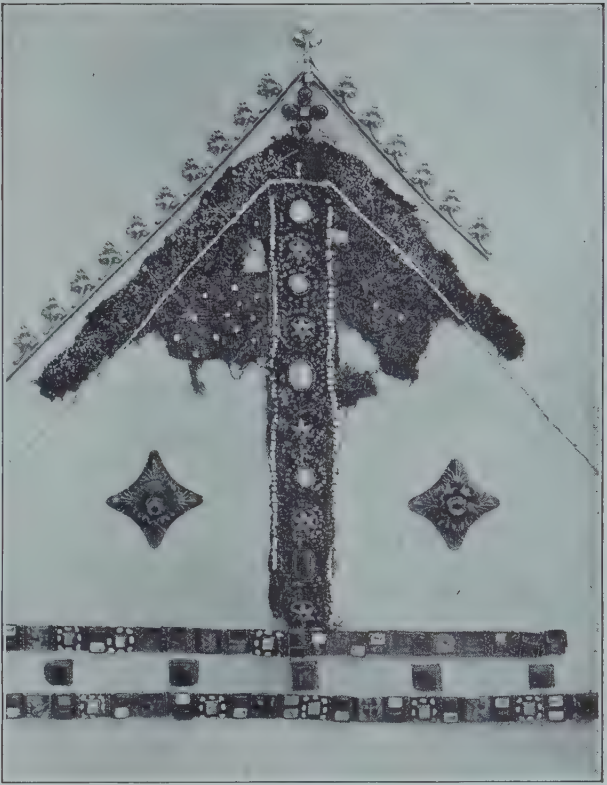


FIG. 6.—Mitre (restored) of William of Wykeham, Bishop of Winchester (d. 1404), preserved at New College, Oxford.

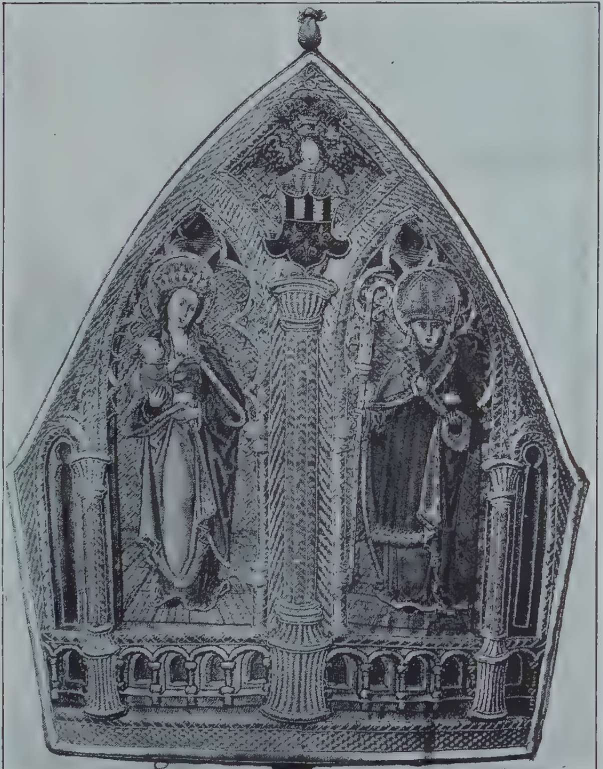

FIG. 7.—Flemish Mitre, embroidered in gold thread, and the panels in colours, with figures of the Virgin and St. Augustine. The other side is similar, with figures of St. Leonard and St. Mary Magdalene. It is dated 1592, repaired in 1766.

In the Victoria and Albert Museum.

an actual mitre or the figure of one was sometimes carried, and sometimes suspended over the tomb" (*Report on the Ornaments of the Church*, p. 106). The liturgical use of the mitre was revived in the Church of England in the latter part of the 19th century, and is now fairly widespread.

3. *Oriental Rites.*—Some form of liturgical head-dress is common to all the Oriental rites. In the Orthodox Eastern Church the mitre (Gr. μίτρα; Slav. *mitra*) is, as in the Western Church, proper only to bishops. Its form differs entirely from that of the Latin Church. In general it rather resembles a closed crown, consisting of a circlet from which rise two arches intersecting each other at right angles. Circlet and arches are richly chased and jewelled; they are filled out by a cap of stiff material, often red velvet, ornamented with pictures in embroidery or *appliqué* metal. Surmounting all, at the intersection of the arches is a cross. In Russia this usually lies flat, only certain metropolitans, and by prescription the bishops of the eparchy of Kiev, having the right to have the cross upright (see fig. 2). In the Armenian Church priests and archdeacons, as well as the bishops, wear a mitre. That of the bishops is of the Latin form, a custom dating from a grant of Pope Innocent III.; that of the priests, the *sagvahart*, is not unlike the Greek mitre (see fig. 3). In the Syrian Church only the patriarch wears a mitre, which resembles that of the Greeks. The *biruna* of the Chaldaean Nestorians, on the other hand, worn by all bishops, is a sort of hood ornamented with a cross. Coptic priests and bishops wear the *ballin*, a long strip of stuff ornamented with crosses &c., and wound turban-wise round the head; the patriarch of Alexandria has a helmet-like mitre, the origin of which is unknown, though it perhaps antedates the appearance of the *phrygium* at Rome. The Maronites, and the uniate Jacobites, Chaldaeans and Copts have adopted the Roman mitre.

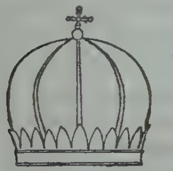
FIG. 2.—Greek Mitre.



From Braun's *Liturgische Gewandung*. By permission of B. Herder.

FIG. 3.—Mitre of Armenian Priest.

The mitre was only introduced into the Greek rite in comparatively modern times. It was unknown in the earlier part of the 15th century, but had certainly been introduced by the beginning of the 16th. Father Braun suggests that its assumption by the Greek patriarch was connected with the changes due to the capture of Constantinople by the Turks. Possibly, as its form suggests, it is based on the imperial crown and symbolized at the outset the quasi-sovereignty over the *rayah* population which Mahommed II. was content to leave to the patriarch. In 1589 it was introduced into Russia, when the tsar Theodore erected the Russian patriarchate and bestowed on the new patriarch the right to wear the mitre, sakkos and mandyas, all borrowed from the Greek rite. A hundred years later the mitre, originally confined to the patriarch, was worn by all bishops.

FIG. 4.—*Mitra pretiosa* of the late Cardinal Vaughan, Roman Catholic Archbishop of Westminster.

See J. Braun, S.J., *Die liturgische Gewandung* (Freiburg-im-Breisgau, 1907), pp. 424–498. The question of the use of the mitre in the Anglican Church is dealt with in the *Report of the Sub-Committee of the Convocation of Canterbury on the Ornaments of the Church and its Ministers* (1908). See also the bibliography to the article VESTMENTS. (W. A. P.)

MITROVICA (Hungarian, *Mitrovicz*; German, *Mitrowitz*), a town of Croatia-Slavonia, Hungary, situated on the river Save, in the county of Syrmia. Pop. (1900), 11,518. Mitrovica is on the railway from Agram, 170 m. W.N.W. to Belgrade, 38 m. E. by S. Roman remains have been discovered in its neighbourhood, and it occupies the site of *Sirmium* or *Syrmium*, the chief city of Lower Pannonia under Roman rule. The emperor Probus (232–282) was born and buried at Sirmium, where, according to some authorities, the emperor Marcus Aurelius (121–180) also died; but this is uncertain. In 351, 357 and 358, ecclesiastical councils of some importance met at Sirmium, which became an episcopal see about 305, and was united with the diocese of Bosnia in 1773. The city was sacked by the Huns in 441, and by the Turks, who destroyed all its ancient buildings, in 1396 and 1521.

MITSCHERLICH, EILHARDT (1794–1863), German chemist, was born on the 7th of January 1794 at Neuende near Jever, in the grand duchy of Oldenburg, where his father was pastor. His uncle, CHRISTOPH WILHELM MITSCHERLICH (1760–1854), professor at Göttingen, was in his day a celebrated scholar. He was educated at Jever under the historian F. C. Schlosser, when he went to Heidelberg in 1811, devoted himself to philology, giving special attention to the Persian language. In 1813 he went to Paris to obtain permission to join the embassy which Napoleon I. was to send to Persia. The events of 1814 put an end to this, and Mitscherlich resolved to study medicine in order that he might enjoy that freedom of travel usually allowed in the East to physicians. He began at Göttingen with the study of chemistry, and this so arrested his attention that he gave up the journey to Persia. From his Göttingen days dates the treatise on certain parts of Persian history, compiled from MSS. in the university library and published in Persian and Latin in 1814, under the title *Mirchondi historia Thaheridarum historicis nostris hucusque incognitorum Persiae principum*. In 1818 he went to Berlin and worked in the laboratory of H. F. Link (1767–1851). There he made analyses of phosphates and phosphites, arsenates and arsenites, confirming the conclusions of J. J. Berzelius as to their composition; and his observation that corresponding phosphates and arsenates crystallize in the same form was the germ from which grew the theory of isomorphism which he communicated to the Berlin Academy in December 1819. In that year Berzelius suggested Mitscherlich to the minister Altenstein as successor to M. H. Klaproth at Berlin. Altenstein did not immediately carry out this proposal, but he obtained for Mitscherlich a government grant to enable him to continue his studies in Berzelius's laboratory at Stockholm. He returned to Berlin in 1821, and in the summer of 1822 he delivered his first lecture as extraordinary professor of chemistry in the university, where in 1825 he was appointed ordinary professor. In the course of an investigation into the slight differences discovered by W. H. Wollaston in the angles of the rhombohedra of the carbonates isomorphous with calc-spar, he observed that the angle in the case of calc-spar varied with the temperature. On extending his inquiry to other aelotropic crystals he observed a similar variation, and was thus led, in 1825, to the discovery that aelotropic crystals, when heated, expand unequally in the direction of dissimilar axes. In the following year he discovered the change, produced by change of temperature, in the direction of the optic axes of selenite. His investigation (also in 1826) of the two crystalline modifications of sulphur threw much light on the fact that the two minerals calc-spar and aragonite have the same composition but different crystalline forms, a property which Mitscherlich called dimorphism. In 1833 he made a series of careful determinations of the vapour densities of a large number of volatile substances, confirming Gay-Lussac's law. He obtained selenic acid in 1827 and showed that its salts are isomorphous with the sulphates, while a few years later he proved that the same thing is true of the manganates and the sulphates, and of the permanganates and the perchlorates. He investigated the relation of benzene to benzoic acid and to other derivatives. In 1829–1830 he published his *Lehrbuch der Chemie*, which embodied many original observations. His interest in mineralogy led him to study the geology of volcanic regions, and he made frequent visits to the Eifel with a view to the discovery of a theory of volcanic action. He did not, however, publish any papers on the subject, though after his death his notes were arranged and published by Dr J. L. A. Roth in the *Memoirs* of the Berlin Academy (1866). In December 1861 symptoms of heart-disease made their appearance, but he was able to carry on his academical work till December 1862. He died at Schönberg near Berlin, on the 28th of August 1863.

Mitscherlich's published papers are chiefly to be found in the *Abhandlungen* of the Berlin Academy, in *Poggendorff's Annalen*, and in the *Annales de chimie et de physique*. The 4th edition of the *Lehrbuch der Chemie* was published in 1844–1847, a 5th was begun in 1855, but was not completed.

MITTEN, a covering for the hand, with a division for the thumb only, and reaching to the lower joint of the fingers; it is made of silk, lace, wool or other material. The word is of obscure origin; it has been connected with Ger. *mitte*, middle, half, in the sense of that which half covers the hand. There are several Celtic words which may be cognate, *e.g.* Irish *miotag*, *mutan*, a thick glove, mitten, such as is worn by hedgers and ditchers. The 16th-century French word *miton* meant a gauntlet. A fine mitten made of lace or open network and extending well up the forearm was much worn by ladies in the early part of the 19th century, and has been fashionable at various times since that date.

MITTWEIDA, a town of Germany in the kingdom of Saxony, on the Zschopau, 12 m. by rail N. of Chemnitz on the railway to Döbeln and Riesa. Pop. (1905), 17,465. It has a handsome Evangelical church, a classical, a modern and a technical school, and cotton and spinning mills. Other industries are the making of furniture, machinery, cigars and cement.

MIVART, ST GEORGE JACKSON (1827–1900), English biologist, was born in London on the 30th of November 1827, and educated at Clapham grammar-school, Harrow, and King's College, London, and afterwards at St Mary's, Oscott, since his conversion to Roman Catholicism prevented him from going to Oxford. In 1851 he was called to the bar, but he devoted himself to medical and biological studies. In 1862 he was appointed lecturer at St Mary's Hospital medical school, in 1869 he became a fellow of the Zoological Society, and from 1874 to 1877 he was professor of biology at the short-lived Roman Catholic University College, London. In 1873 he published *Lessons in Elementary Anatomy*, and an essay on *Man and Apes*. In 1881 appeared *The Cat: an Introduction to the Study of Back-boned Animals*. The careful and detailed work he bestowed on Insectivora and Carnivora largely increased our knowledge of the anatomy of these groups. In 1871 his *Genesis of Species* brought him into the controversy then raging. Though admitting evolution generally, Mivart denied its applicability to the human intellect.

His views as to the relationship existing between human nature and intellect and animal nature in general were given in *Nature and Thought* (1882); and in the *Origin of Human Reason* (1889) he stated what he considered the fundamental difference between men and animals. In 1884, at the invitation of the Belgian episcopate, he became professor of the philosophy of natural history at the university of Louvain, which had conferred on him the degree of M.D. in 1884. Some articles published in the *Nineteenth Century* in 1892 and 1893, in which Mivart advocated the claims of science even where they seemed to conflict with religion, were placed on the *Index expurgatorius*, and other articles in January 1900 led to his excommunication by Cardinal Vaughan, with whom he had a curious correspondence vindicating his claim to hold liberal opinions while remaining in the Roman Catholic Church. Shortly afterwards he died, in London, on the 1st of April 1900. Mivart was also the author of many scientific papers and occasional articles, and of *Castle and Manor: a Tale of our Time* (1900), which originally appeared in 1894 as *Henry Standon*, by "D'Arcy Drew."

MIZPAH, or Mizpeh, the name of several places referred to in the Old Testament, in each case probably derived from a "commanding prospect," the Hebrew name having that significance. (1) Mizpah of Gilead, where Jacob was reconciled to Laban (Gen. xxxi. 49); apparently the site of the camp of the Israelites when about to attack the Ammonites under Jephthah's leadership (Judges x. 17). This ancient sanctuary was probably the scene of Jephthah's vow (Judges xi. 29; cf. *v.* 11). The identification of this Mizpeh is a difficult problem: it is supposed to be the same as Ramoth Gilead, but the evidence is scarcely conclusive. It is referred to in Hos. v. 1. (2) Mizpah of Benjamin. It has been suggested, on hardly sufficient grounds, that the Mizpeh where the Hebrews assembled before the extermination of the Benjamites (Judges xx. 1) was not the shrine where Samuel made his headquarters (1 Sam. vii. 5). It was fortified by Asa (1 Kings xv. 22), and after the destruction of Jerusalem was the seat of government under the viceroy Gedaliah (2 Kings xxv. 23): here Gedaliah was murdered (ibid. 25). After the exile it retained the tradition of being a seat of government (Neh. iii. 7) and a holy place (1 Macc. iii. 46). It is probably to be identified with the mountain, Neby Samwil, north of Jerusalem, still considered sacred by the Moslems: a Crusaders' church (now a mosque), covers the traditional tomb of Samuel. (3) A territory near Mount Hermon, a seat of the Hivites, which joined the coalition of Jabin against Joshua (Joshua xi. 3). In the territory was the "valley of Mizpeh" (*v.* 8) where the Canaanites were routed. (4) A town in the tribe of Judah (Joshua xv. 38). (5) Mizpeh of Moab, where David interviewed the king of Moab and found an asylum for his parents (1 Sam. xxii. 3). (R. A. S. M.)

MIZRAIM, the biblical name for Egypt (Gen. x. 6, 13, Hebrew *Miṣrayim*; the apparently dual termination *-aim* may be due to a misunderstanding); there is an alternative poetical form Māṣōr (2 Kings xix. 24, &c.). In Isa. xi. 11 the name is kept distinct from Pathros or Upper Egypt, and represents some portion at least of Lower Egypt. It perhaps means "boundary" or "frontier," a somewhat ambiguous term, which illustrates the topographical problems. First (*a*), E. Schrader pointed out in 1874 that the Assyrians knew of some Muṣri (*i.e.* Mizraim) in North Syria, and it is extremely probable that this land is referred to in 2 Kings vii. 6 (mentioned with the Hittites), and in 1 Kings x. 28 seq., 2 Chron. i. 16 seq., where the word for "droves" (Heb. *m-q-v-h*) conceals the contiguous land Kuë (Cilicia).[1] Next (*b*), C. T. Beke, as long ago as 1834, concluded in his *Origines biblicae* (p. 167 *et passim*) that "Egypt" in the Old Testament sometimes designates a district near Midian and the Gulf of 'Akaba, and the view restated recently and quite independently by H. Winckler on later evidence (1893) has been the subject of continued debate. Egypt is known to have laid claim to the southern half of Palestine from early times, and consequently the extension of the name of Egypt beyond the limits of Egypt and of the Sinaitic peninsula, is inherently probable. When, for example, Hagar, the "Egyptian," is the ancestress of Ishmaelite tribes, the evidence makes it very unlikely that the term is to be understood in the strict ethnical sense; and there are other passages more suitably interpreted on the hypothesis that the wider extension of the term was once familiar. In the second half of the 8th century B.C., Assyrian inscriptions allude to a powerful Muṣri at a time when the Nile empire was disintegrated and scarcely in a position to play the part ascribed to it (*i.e.* if by Muṣri we are to understand Egypt).[2] Not until the supremacy of Tirhakah does the ambiguity begin to disappear, and much depends upon the unbiased discussion of the related biblical history (especially the writings of Isaiah and Hosea) and the Egyptian data. But even in the period of disintegration the minor princes of the Delta were no doubt associated with their eastern neighbours, and although the Assyrian Muṣri stands in the same relation to the people of Philistia as do the Edomites and allied tribes of the Old Testament, Philistia itself was always intimately associated with Egypt. (See PHILISTINES.)

---

[1] See further, H. Winckler, *Alt. test. Untersuch.* (1892), pp. 168-174.

[2] So, too, according to one passage, Tiglath-pileser IV. appoints a governor over Muṣri before Egypt itself had actually been conquered.

The problem is complicated by the obscurity which overhangs the history of south Palestine and the Delta (see EDOM; MIDIAN). The political importance of Egypt was not constant, and the known fluctuations of geographical terms combine with the doubtful accuracy of early writers to increase the difficulties. The Assyrian evidence alone points very strongly to a Muṣri in north-west Arabia; the biblical evidence alone suggests an extra-Egyptian Miṣrayim. On the whole the result of discussion has been to admit the probability that Miṣrayim could refer to a district outside the limits of Egypt proper. But it has not justified the application of this conclusion to all the instances in which some critics have relied upon it, or the sweeping inferences and reconstructions which have sometimes been based upon it. Each case must be taken on its merits.

Gesell.* (1898), pp. 1 sqq., 169 sqq.; *Hibbert Journal* (April 1904); *Keilinschr. u. das alte Test.*, 3rd ed., 136 sqq.; and *Im Kampfe um den alten Orient*, ii. (1907); T. K. Cheyne, especially *Kingdom of Judah* (1908), pp. xiv. sqq.; F. Hommel, *Vier neue arab. Landschaftsnamen in A.T.* For criticisms (many of them somewhat captious) see König's reply to Hommel (Berlin, 1902), A. Noordtzij, *Theolog. Tijdsch.* (1906, July, September), and E. Meyer, *Israeliten u. ihre Nachbarstämme*, pp. 455 sqq. A valuable survey of the geographical and other conditions is given by N. Schmidt, *Hibbert Journal* (January 1908). (S. A. C.)

MNEMONICS (from Gr. *μνᾶσθαι*, remember; whence *μνήμων*, mindful; *τὸ μνημονικόν*, *sc.* *τέχνημα*, that which mechanically aids the memory), the general name applied to devices for aiding the memory. Such devices are also described as *memoria technica*. The principle is to enable the mind to reproduce a relatively unfamiliar idea, and specially a series of dissociated ideas, by connecting it, or them, in some artificial whole, the parts of which are mutually suggestive. A pupil is far more likely to remember the cities which claimed to be the birthplace of Homer when he remembers that their names can be made to form the hexameter line, "Smyrna, Chios, Colophon, Salamis, Rhodos, Argos, Athenae." Among the most famous examples of metrical mnemonics are the "gender rhymes" of the Latin grammars, the hexameter lines (especially that beginning "Barbara Celarent") invented by logicians (for a list see Baldwin's *Dict. of Philos.*, vol. ii., *s.v.* "Mnemonic Verses"), the verse for remembering the number of days in the months ("Thirty days hath September, April, June and November"). Other devices are numerous. Thus the name and lights of the sides of a ship may be remembered because the three shorter words "port," "left," "red," go together, as compared with the longer, "starboard," "right," "green."

Memory is commonly classified by psychologists according as it is exercised (*a*) *mechanically*, by attention and repetition; (*b*) *judiciously*, by careful selection and co-ordination; and (*c*) *ingeniously*, by means of artifices, *i.e.* mnemotechny, mnemonics. It must, however, be observed that no mnemonic is of any value which does not possess the qualities of (*a*) and (*b*). A mnemonic is essentially a device which uses attention and repetition, and careful selection is equally necessary. A more accurate description of mnemonics is "mediate" or "indirect" memory. In the technical sense the word "mnemonic" is confined to the systems of general application which have been elaborated by various writers.

Systems.—Mnemonic devices were much cultivated by Greek sophists and philosophers, and are repeatedly referred to by Plato and Aristotle. In later times the invention was ascribed to the poet Simonides,[1] perhaps for no other reason than that the strength of his memory was famous. Cicero, who attaches considerable importance to the art, but more to the principle of order as the best help to memory, speaks of Carneades (or perhaps Charmades) of Athens and Metrodorus of Scepsis as distinguished examples of the use of well-ordered images to aid the memory. The latter is said by Pliny to have carried the art so far "ut nihil non iisdem verbis redderet auditum." The Romans valued such helps as giving facility in public speaking. The method used is described by the author of *Rhet. ad Heren.*, iii. 16–24; see also Quintilian (*Inst. Or.* xi. 2), whose account is, however, somewhat incomplete and obscure. In his time the art had almost ceased to be practised. The Greek and Roman system of mnemonics was founded on the use of mental places and signs or pictures, known as "topical" mnemonics. The most usual method was to choose a large house, of which the apartments, walls, windows, statues, furniture, &c., were severally associated with certain names, phrases, events or ideas, by means of symbolic pictures; and to recall these it was only necessary to search over the apartments of the house till the particular place was discovered where they had been deposited by the imagination. In accordance with this system, if it were desired to fix an historic date in the memory, it was localized in an imaginary town divided into a certain number of districts, each with ten houses, each house with ten rooms, and each room with a hundred quadrates or memory-places, partly on the floor, partly on the four walls, partly on the roof. Thus, if it were desired to fix in the memory the date of the invention of printing (1436), an imaginary book, or some other symbol of printing, would be placed in the thirty-sixth quadrate or memory-place of the fourth room of the first house of the historic district of the town. Except that the rules of mnemonics are referred to by Martianus Capella, nothing further is known regarding the practice of the art until the 13th century. Among the voluminous writings of Roger Bacon is a tractate *De arte memorativa*. Raimon Lull devoted special attention to mnemonics in connexion with his *ars generalis*. The first important modification of the method of the Romans was that invented by the German poet Konrad Celtes, who, in his *Epitoma in utramque Ciceronis rhetoricam cum arte memorativa nova* (1492), instead of places made use of the letters of the alphabet. About the end of the 15th century Petrus de Ravenna (b. 1448) awakened such astonishment in Italy by his mnemonic feats that he was believed by many to be a necromancer. His *Phoenix artis memoriae* (Venice, 1491, 4 vols.) went through as many as nine editions, the seventh appearing at Cologne in 1608. An impression equally great was produced about the end of the 16th century by Lambert Schenkel (*Gazophylacium*, 1610), who taught mnemonics in France, Italy, and Germany, and, although he was denounced as a sorcerer by the university of Louvain, published in 1593 his tractate *De memoria* at Douai with the sanction of that celebrated theological faculty. The most complete account of his system is given in two works by his pupil Martin Sommer, published at Venice in 1619. In 1618 John Willis (d. 1628?) published *Mnemonica; sive ars reminiscendi* (Eng. version by Leonard Sowersby, 1661; extracts in Feinaigle's *New Art of Memory*, 3rd ed., 1813), containing a clear statement of the principles of topical or local mnemonics. Giordano Bruno, in connexion with his exposition of the *ars generalis* of Lull, included a *memoria technica* in his treatise *De umbris idearum*. Other writers of this period are the Florentine Publicius (1482); Johann Romberch (1533); Hieronimo Morafiot, *Ars memoriae* (1602); B. Porta, *Ars reminiscendi* (1602).

In 1648 Stanislaus Mink von Wenussheim or Winckelmann made known what he called the "most fertile secret" in mnemonics—namely, the use of consonants for figures, so as to express numbers by words (vowels being added as required); and the philosopher Leibnitz adopted an alphabet very similar to that of Winckelmann in connexion with his scheme for a form of writing common to all languages. Winckelmann's method, which in fact is adopted with slight changes by the majority of subsequent "original" systems, was modified and supplemented in regard to many details by Richard Grey (1694–1771), who published a *Memoria technica* in 1730. The principal part of Grey's method (which may be compared with the Jewish system by which letters also stand for numerals, and therefore words for dates) is briefly this: "To remember anything in history, chronology, geography, &c., a word is formed, the beginning whereof, being the first syllable or syllables of the thing sought, does, by frequent repetition, of course draw after it the latter part, which is so contrived as to give the answer. Thus, in history, the Deluge happened in the year before Christ two thousand three hundred forty-eight; this is signified by the word Del-*etok*, Del standing for Deluge and *etok* for 2348." To assist in retaining the mnemonical words in the memory they were formed into memorial lines, which, however, being composed of strange words in difficult hexameter scansion, are by no means easy to memorize. The vowel or consonant, which Grey connected with a particular figure, was chosen arbitrarily; but in 1806 Gregor von Feinaigle, a German monk from Salem near Constance, began in Paris to expound a system of mnemonics, one feature (based on Winckelmann's system) of which was to represent the numerical figures by letters chosen on account of some similarity to the figure to be represented or some accidental connexion with it. This alphabet was supplemented by a complicated system of localities and signs. Feinaigle, who apparently published nothing himself, came to England in 1811, and in the following year one of his pupils published *The New Art of Memory*, which, beside giving Feinaigle's system, contains valuable historical material about previous systems. A simplified form of Feinaigle's method was published by Aimé Paris (*Principes et applications diverses de la mnémonique*, 7th ed., Paris, 1834), and the use of symbolic pictures was revived in connexion with the latter by a Pole, Antoni Jaźwińsky, of whose system an account was published by the Polish general J. Bem, under the title *Exposé général de la méthode mnémonique polonaise, perfectionnée à Paris* (Paris, 1839). Various other modifications of the systems of Feinaigle and Aimé Paris were advocated by subsequent mnemonists, among them being the *Phrenotypics* of Major Beniowsky, a Polish refugee, the *Phreno-Mnemotechny* (1845) of François Fauvel Gouraud the *Mnemotechnik* of Karl Otto Reventlow (generally known as Karl Otto), a Dane, and the *Mnemotechny* of the American Pliny Miles.

---

[1] Pliny, *H.N.* vii. 24. Cicero, *De or.* ii. 86, mentions this belief without committing himself to it.

The more complicated mnemonic systems have fallen almost into complete disuse; but methods founded chiefly on the so-called laws of association (see Association of Ideas) have been taught with some success in Germany by, among others, Hermann Kothe, author of *Lehrbuch der Mnemonik* (2nd ed., Hamburg, 1852), and *Katechismus der Gedächtnisskunst* (6th ed. by Montag, Leipzig, 1887); and Hugo Weber-Rumpe, author of *Mnemonische Zahlwörterbuch* (Breslau, 1885) and *Mnemonische Unterrichtsbriefe* (1887–1888); in England by Dr Edward Pick, whose *Memory and the Rational Means of Improving it* (5th ed., 1873) and *Lectures on Memory Culture* (1899) obtained a wide circulation. Passing over the work of William Day (*New Mnemonical Chart and Guide to the Art of Memory*, 1845), Rev. T. Brayshaw (*Metrical Mnemonics*, a very rare work), Fairchild and W. Stokes, the next name of any importance is the Rev. J. H. Bacon, a pupil of Edward Pick. His book (*A Complete Guide to the Improvement of the Memory*, 3rd ed., rev. 1890) contains a good summary of the history of mnemonics and a very reasonable account of the principles; it gains in value by its comparative simplicity. More or less successful systems were issued by Lyon Williams (1866), T. Maclaren (1866), Thomas A. Sayer (1867), Rev. Alexander Mackay (1869), George Crowther (1870), F. Appleby (1880), John Sambrook, who made use of similarities in sounds (gun, 1; Jew, 2), the French scientist Abbé Moigno, J. H. Noble, and Allan Dalzell. Considerable interest was roused both in London and in America by the controversy which raged round the system of "Alphonse Loisette," who taught his "art of never forgetting" successively in London and Washington. It claimed to be original in system, but was attacked in England by F. Appleby and in America by George S. Fellows, and is generally regarded as both unoriginal and inferior on the whole to preceding systems (for the litigation in America see *e.g.* Part II. of Middleton's *Memory Systems*, pp. 96 sqq.). An interesting work (*Memoranda mnemonica*) was published by James Copner in 1893, containing a system based partly on the use of letters for figures and words for dates, as well as a large number of rhymes for remembering facts in biblical, Roman, Greek and English history. He made use of Grey's system, but endeavoured as far as possible to invent, where necessary, words and terminations which in themselves had some special fitness in place of Grey's monstrosities. More complicated systems are the *Keesing Memory System* (Auckland, 1896), the Smith-Watson *System of Memory and Mental Training* (Washington), and the Pelman memory system.

Bibliography.—A large number of the works referred to in the text contain historical material. Among histories of the subject, see C. F. von Aretin, *Systematische Anleitung zur Theorie und Praxis der Mnemonik* (Sulzberg, 1810); A. E. Middleton, *Memory Systems, Old and New* (espec. 3rd rev. ed., New York, 1888), with bibliography of works from 1325 to 1888 by G. S. Fellows and account of the Loisette litigation; F. W. Colegrove, *Memory* (1901), with bibliography, pp. 353–361. (J. M. M.)

MNESICLES, the architect of the great Propylaea of the Athenian Acropolis, set up by Pericles about 437 B.C.

MOA, apparently the Maori name of the extinct Ratite birds in New Zealand, comprising the group Dinornithes (cf. Bird: *Classification*; and Ratitae). The earliest account of these birds is that of Polack (*New Zealand*, London, 1838), who speaks of the former existence of some struthious birds in the north island as proved by fossil bones which were shown to him. "The natives added that, in times long past, they received the tradition that very large birds had existed, but the scarcity of food, as well as the easy method of entrapping them, had caused their extermination." In the North Island the moas seem to have died out soon after the arrival of the Maoris, according to F. W. Hutton, some 700-500 years ago. In the South Island they seem to have lingered much longer, possibly, according to H. O. Forbes (*Nat Sci.* II. 1893, pp. 374–380), "down even to the time that Captain Cook visited New Zealand." But these are only surmises, based upon the fact that in various dry caves limbs still surrounded by the mummified flesh and skin, feathers, and even eggs with the inner membrane, have been found. Great quantities of bones have been found in caves and in swamps, so that now nearly every part of the skeleton, of some kind or other, is known.

The most striking feature of the moas, besides the truly gigantic size of some species, is the almost complete absence of the wings. In fact, the whole skeletons of the wings and of the shoulder girdle seem to have been lost, excepting *Anomalopteryx dromaeoides*, which, according to Hutton,[1] had still some vestiges. Such a complete reduction of the whole anterior limb and girdle is unique among birds, but the cassowaries indicate the process. In conformity with these reductions the breastbone of the moas is devoid of any coracoidal facets; there is no trace of a keel, and the number of sternal ribs is reduced to three or even two pairs. The hind limbs are very strong; the massive femur has a large pneumatic foramen; the tibia has a bony bridge on the anterior surface of the lower portion, a character in which the moas agree only with *Apteryx* amongst the other Ratitae. The number of toes is four, unless the hallux is more or less reduced. The pelvis much resembles that of the kiwis.

The skull has been monographed by T. J. Parker ("On the Cranial Osteology, Classification and Phylogeny of the Dinornithidae," *Tr. Z. Soc.* (1893), xiii. 373–431, pls. 56–62); it resembles in its general configuration that of the emeus and cassowaries, while it differs from that of *Apteryx* most obviously by the short and stout bill.

The feathers have a large after-shaft which is of the size of the other half, likewise in agreement with the Australian Ratitae, while in the others, including the kiwis, the after-shaft is absent. Another important point, in which the moas agree with the other Ratitae and differ from the kiwis, are the branched, instead of simple, porous canals in the eggshell.

---

[1] "The Moas of New Zealand," *Tr. N. Zea. Inst.* (1892), xxiv. 93–172, pls. xv.–xvii.

The affinities of the moas are undoubtedly with the Australian Ratitae, and, in spite of the differences mentioned above, with the kiwis. In this respect Max Fürbringer and T. J. Parker are in perfect agreement. The relationship with *Aepyornis* of Madagascar is still problematic. Whilst the moas seem to have been entirely herbivorous, feeding not unlikely upon the shoots of ferns, the kiwis have become highly specialized worm-eaters. In this respect cassowaries and emeus hold an intermediate position, their occasional zoophagous (especially piscivorous) inclination being well known. Unmolested by enemies (*Harpagornis*, a tremendous bird of prey, died out with the Pleistocene), living in an equable insular climate, with abundant vegetation, the moas flourished and seem to have reached their greatest development in specialization, numbers, and a bewildering variety of large and small kinds, within quite recent times. Unfortunately no fossil moas, older than the Pleiocene, are known. Parker recognizes five genera, with about twenty species, which he combines into three sub-families: Dinornithinae with *Dinornis*, Anomalopteryginae with *Pachyornis*, *Mesopteryx* and *Anomalopteryx*, comprising the comparatively least specialized forms; and Emeinae with the genus *Emeus*, not to be confounded with the vernacular emeu. The moas ranged in size from that of a turkey to truly colossal dimensions, the giant being *Dinornis maximus*, which, with a tibial length of 39 in., stood with its small head about 12 ft. above the ground.

(H. F. G.)

MOAB, the name of an ancient people of Palestine who inhabited a district E. of the Jordan and the Dead Sea, lying N. of Edom and S. of Ammon (*q.v.*) and the Israelite Transjordanic districts. There is little material for its earlier history outside the Old Testament, and the various references in the latter are often of disputed reference and date. The national traditions of Israel recognize a close relationship between Moab and Ammon, "sons" of Lot, and the "brothers" Esau (Edom) and Jacob (Israel), and Moab is represented as already a powerful people when Israel fled from Egypt (Exod. xv. 15). The detailed narratives, however, give conflicting views of the exodus and the conquest of Palestine. It was supposed that Moab, having expelled the aboriginal giants, was in turn displaced by the Amorite king Sihon, who forced Moab south of the Arnon (Wadi Mōjib, a natural boundary) and drove Ammon beyond the Jabbok. The Israelites at Kadesh, almost at the gate of the promised land, incurred the wrath of Yahweh, and, deterred by a defeat at Hormah from pursuing their journey northwards, were obliged to choose another route (Num. xiv. 40-45; contrast xxi. 1-3). (See EXODUS, THE.) Messengers to Edom were repulsed (Num. xx. 14-18), or Israel was met by Edom with force (*v.* 19 seq.); consequently a great détour was made from Kadesh round by the south of Edom (Num. xiv. 25, xxi. 4; Judges xi. 18). At length the people safely reached Pisgah in Moab (Num. xxi. 16-20; cf. Deut. iii. 27, xxxiv. 1), or, according to another view, passed outside Moab until they reached the border of Sihon's kingdom (Num. xxi. 13, 26; Judges xi. 17 seq.). There are other details in Deut. ii., and the late list in Num. xxxiii. even seems to assume that the journey was made from Kadesh across the northern end of Edom. Apparently no fixed or distinct tradition existed regarding the journeys, and it extremely probable that some of the most characteristic features belong to much later periods than the latter half of the second millennium B.C., the age to which they are ascribed (*e.g.* the poem on the fall of Heshbon, Num. xxi. 27-30).

The account of Balaam (*q.v.*), the son of Beor, the soothsayer, of the children of Ammon (xxii. 5, some MSS.), or of Aram or of Edom (see Cheyne, *Ency. Bib.*, col. 3685 and below), is noteworthy for the prophecies of Israel's future supremacy; but he is passed over in the historical sketch, Deut. ii.; and even the allusion, ibid. xxiii. 4 seq., belongs to a context which on independent grounds appears to be a later insertion. Israel's idolatry in *Moab* is supplemented by a later story of the vengeance upon *Midian* (xxv. 6-18, xxxi.). In Joshua xiii. 21 the latter is associated with both Sihon and Balaam, and in some obscure manner Midian and Moab are connected in Num. xxii. 4-7 (cf. xxv. 18, xxxi. 8). An Edomite list of kings includes Bela (cf. Bil'am, *i.e.* Balaam), son of Beor, and states that a Hadad, son of Bedad, smote Midian in the field of Moab (Gen. xxxvi. 32, 35); these events, assigned to an early age, have been connected with the appearance of Moabite power west of the Jordan in the days of the "judge" Ehud (*q.v.*). However, all that is recorded in Num. xxii. sqq., together with various legal and other matter, now severs the accounts of the Israelite occupation of east Jordan (Num. xxi. 33-35, xxxii. 39-42). For full details see G. B. Gray, "Numbers" (*Internat. Critical Comment.*).

Although Moab and Ammon were "brothers," their history was usually associated with that of Judah and Israel respectively, and naturally depended to a considerable extent upon these two and their mutual relations. Jephthah (*q.v.*), one of the Israelite "judges," delivered Gilead from Ammon, who resumed the attack under its king Nahash, only to be repulsed by Saul (*q.v.*). Ehud (*q.v.*) of Benjamin or Ephraim freed Israel from the Moabite oppression. To the first great kings, Saul and David, are ascribed conquests over Moab, Ammon and Edom. The Judaean David, for his part, sought to cultivate friendly relations with Ammon, and tradition connects him closely with Moab. His son Solomon contracted marriages with women of both states (1 Kings xi. 5, 7), thus introducing into Jerusalem cults which were not put down until almost at the close of the monarchy (2 Kings xxiii. 13). In the 9th century B.C. the two states appear in more historical surroundings, and the discovery of a lengthy Moabite inscription has thrown valuable light upon contemporary conditions.

This inscription, now in the Louvre, was found at Dhībān, the biblical Dībōn, in 1868 by the Rev. F. Klein, a representative of the Church Missionary Society stationed at Jerusalem. It contains a record of the successes gained by the Moabite king Mesha against Israel.[1] Omri (*q.v.*) had previously seized a number of Moabite cities north of the Arnon, and for forty years the Moabite national god Chemosh was angry with his land. At length he roused Mesha; and Moab, which had evidently retreated southwards towards Edom, now began to take reprisals. "The men of Gad had dwelt in the land of 'Ataroth from of old; and the king of Israel built 'Ataroth for himself." Mesha took the city, slew its people in honour of Chemosh, and dragged before the god the altar-hearth (or the priests?) of D-v-d-h (apparently a divine name, but curiously similar to David). Next Chemosh roused Mesha against the city of Nebo. It fell with its thousands, for the king had "devoted" it to the deity 'Ashtar-Chemosh. Yahweh had been worshipped there, and his . . . (? vessels, or perhaps the same doubtful word as above) were dragged before the victorious Chemosh. With the help of these and other victories (at Jahaz, Aroer, &c.), Moab recovered its territory, fortified its cities, supplied them with cisterns, and Mesha built a great sanctuary to his god. The inscription enumerates many places known elsewhere (Isa. xv.; Jer. xlviii.), but although it mentions the "men of Gad," makes no allusion to the Israelite tribe Reuben, whose seat lay in the district (Num. xxxii.; Josh. xiii. 15-23; see REUBEN). The revolt will have followed Ahab's death (see 2 Kings i. 1) and apparently led to the unsuccessful attempt by Jehoram to recover the lost ground (ibid. iii.).

The story of Jehoram in 2 Kings iii. now gives prominence to Elisha, his wonders, his hostility to the ruling dynasty and his regard for the aged Jehoshaphat of Judah. Following other synchronisms, the Septuagint (Lucian's recension) names Ahaziah of Judah; from 2 Kings i. 17, the reigning king could only have been Jehoram's namesake. The king of Edom appears as an ally of Israel and Judah (contrast 1 Kings xxii. 47; 2 Kings viii. 20), and hostile to Moab (comp. above, and the obscure allusion in Amos ii. 1-2). But the king of Moab's attempt to break through unto him suggests that in the original story (there are several signs of revision) Moab and Edom were in alliance. In this case the object of Jehoram's march round the south of the Dead Sea was to drive a wedge between them, and the result hints at an Israelite disaster. Singularly enough, Jehoram of Judah suffered some defeat from Edom at Zair, an unknown name for which Ewald suggested (the Moabite) Zoar (2 Kings viii. 21; see JEHORAM).

Moab thus retained its independence, even harrying Israel with marauding bands (2 Kings xiii. 20), while Ammon was perpetrating cruelties upon Gilead (Am. i. 13 sqq.). But under Jeroboam II. (*q.v.*) Israelite territory was extended to the Wadi of the ʻArabah or wilderness (probably south end of the Dead Sea), and again Moab suffered. If Isa. xv. seq. is to be referred to this age, its people fled southwards and appealed for protection to the overlord of Edom (see Uzziah). During the Assyrian supremacy, its king Salamannu (probably not the Shalman of Hos. x. 14) paid tribute to Tiglath-Pileser IV., but joined the short-lived revolt with Judah and Philistia in 711. When Sennacherib besieged Jerusalem in 701, Kamus(Chemosh)-nadab also submitted, and subsequently both Esarhaddon and Assur-bani-pal mention the Moabite king Muṣuri ("the Egyptian," but cf. Mizraim) among their tributaries. In fact, during the reign of Assur-bani-pal Moab played the vassal's part in helping to repulse the invasion of the Nabayati and nomads of Kedar, a movement which made itself felt from Edom nearly as far as Damascus. It had its root in the revolt of Samas-sum-yukin (Shamash-shun-ukin) of Babylonia, and coming at a time immediately preceding the disintegration of the Assyrian Empire, may have had most important consequences for Judah and the east of the Jordan.[1] (See Palestine: *History*.)

---

[1] See edition by M. Lidzbarski, *Altsemitische Texte*, Bd. I. (Giessen, 1907); also G. A. Cooke, *North Semitic Inscr.*, pp. 1-14, and the articles on "Moab" in Hasting's *Dict. Bible* (by W. H. Bennett), and "Mesha" in *Ency. Bib.* (by S. R. Driver).

Moab shares with Ammon and Edom in the general obscurity which overhangs later events. If it made inroads upon Judah (2 Kings xxiv. 2), it joined the coalition against Babylonia (Jer. xxvii. 3); if it is condemned for its untimely joy at the fall of Jerusalem (Isa. xxv. 9 seq.; Jer. xlviii.; Ezek. xxv. 8–11; Zeph. ii. 8-10), it had offered a harbour to fugitive Jews (Jer. xl. 11). The dates of the most significant passages are unfortunately uncertain. If Sanballat the Horonite was really a native of the Moabite Horonaim, he finds an appropriate place by the side of Tobiah the Ammonite and Gashmu the Arabian among the strenuous opponents of Nehemiah. Still later we find Moab part of the province of Arabia in the hands of fresh tribes from the Arabian desert (Jos. *Ant.* xiii. 13, 5); and, with the loss of its former independent power, the name survives merely as a type (Dan. xi. 41). (See Jews; Nabataeans.)

A populous land commanding the trade routes from Arabia to Damascus, rich in agricultural and pastoral wealth, Moab, as Mesha's inscription proves, had already reached a high state of civilization by the 9th century B.C. Its language differed only dialectically from Hebrew; its ideas and religion were very closely akin to the Israelite, and it may be assumed that they shared in common many features of culture.[2] The relation of Chemosh, the national god, to his "children" (Num. xxi. 29) was that of Yahweh to Israel (see especially Judges xi. 24). He had his priests (Jer. xlviii. 7), and Mesha, perhaps himself a priest-king, receives the oracles direct or through the medium of his prophets. The practice of devoting, banning or annihilating city or community was both Moabite and Israelite (cf. above, also Deut. ii. 34, iii. 6, xx. 10–20; 2 Chron. xxv. 12, &c.), and human sacrifice, offered as an exceptional gift to Chemosh in 2 Kings iii. 27, in Israel to Molech (*q.v.*), was a rite once less rare. Apart from the religious cult suggested in the name Mount Nebo, there were local cults of the Baal of Peor and the Baal of Meon, and Mesha's allusion to ʻAshtar-Chemosh, a compound deity, has been taken to point to a corresponding consort whose existence might naturally be expected upon other grounds (see Astarte). The fertility of Moab, the wealth of wine and corn, the temperate climate and the enervating heat supply conditions which directed the form of cult. Nature-worship, as in Israel, lay at the foundation, and the impure rites of Shittim and Baal-Peor (Num. xxxi. 16; Ps. cvi. 28) would not materially differ from practices which Israelite prophets were called upon to condemn. Much valuable evidence is to be obtained also from the survival of ancient forms of cult in Moab and east of the Jordan (*e.g.* sacrifices on the house roofs) and from a survey of epigraphical and other data from the Greek, Roman, and later periods, allowance being made for contamination. The whole question deserves careful investigation in the light of comparative religion.[3]

The relationship felt between Israel and the external states (Moab, Edom, and Ammon) is entirely justified. It extends intermittently throughout the history, and certain complicated features in the traditions of the southern tribes point to affinities with Moab which find a parallel in the traditions of David (see Ruth) and in the allusions to intercourse between Moab and Benjamin (1 Chron. viii. 8) or Judah (ibid. iv. 21 seq.). But the obscure historical background of the references makes it uncertain whether the exclusiveness of orthodox Judaism (Neh. xiii. 1–3; cf. Deut. xxiii. 3–6; Ezra ix. 1, 12) was imposed upon an earlier catholicity, or represented only one aspect of religious spirit, or was succeeded by a more tolerant attitude. Evidence for the last-mentioned has been found in the difficult narrative in Josh. xxii. But Israel remained a great power in religious history while Moab disappeared. It is true that Moab was continuously hard pressed by desert hordes; the exposed condition of the land is emphasized by the chains of ruined forts and castles which even the Romans were compelled to construct. The explanation of the comparative insignificance of Moab, however, is not to be found in purely topographical considerations. Nor can it be sought in political history, since Israel and Judah suffered as much from external movements as Moab itself. The explanation is to be found within Israel itself, in factors which succeeded in re-shaping existing material and in imprinting upon it a durable stamp, and these factors, as biblical tradition recognizes, are to be found in the work of the prophets.

See the articles on Moab in Hastings's *Dict. Bible* (W. H. Bennett), *Ency. Bib.* (G. A. Smith and Wellhausen), and Hauck's *Realencyklopädie* (F. Buhl) with their references; also the popular description by W. Libbey and F. E. Hoskins, *Jordan Valley and Petra* (1905), and the very elaborate and scientific works by R. E. Brünnow and A. von Domaszewski, *Die Provincia Arabia* (1904–1905), and A. Musil, *Arabia Petraea* (1907–1908). Mention should be made of the mosaic map of Palestine found at Medaba, dating perhaps from the 5th century A.D.; for this, see A. Jacoby, *Das geograph. Mosaik von M.* (1905), and P. Palmer and Guthe (1906). For language and epigraphy see Nabataeans, Semitic Languages; for topography, &c., Palestine; and for the later history, Jews. (S. A. C.)

MOʻALLAKĀT (Moʻallaqāt or Muʻallaqāt). *Al-Moʻallaqāt* is the title of a group of seven longish Arabic poems, which have come down to us from the time before Islam. The name signifies "the suspended" (pl.), the traditional explanation being that these poems were hung up by the Arabs on or in the Kaʻba at Mecca. The oldest passage known to the present writer where this is stated occurs in the *ʻIqd* of the Spanish Arab, Ibn ʻAbd-Rabbihi (A.D. 860–940), Būlāq ed. of 1293 A.H. vol. iii. p. 116 seq. We read there: "The Arabs had such an interest in poetry, and valued it so highly, that they took seven long pieces selected from the ancient poetry, wrote them in gold on pieces of Coptic linen folded up, and hung them up (*ʻallaqat*) on the curtains which covered the Kaʻba. Hence we speak of 'the golden poem of Amra'al Qais,' 'the golden poem of Zuhair.' The number of the golden poems is seven; they are also called 'the suspended' (*al-Moʻallaqāt*)." Similar statements are found in later Arabic works. But against this we have the testimony of a contemporary of Ibn ʻAbd-Rabbihi, the grammarian Nāḥḥās (d. A.D. 949), who says in his commentary on the Moʻallaqāt: "As for the assertion that they were hung up in [*sic*] the Kaʻba, it is not known to any of those who have handed down ancient poems."[4] This cautious scholar is unquestionably right in rejecting a story so utterly unauthenticated. The customs of the Arabs before Mahomet are pretty accurately known to us; we have also a mass of information about the affairs of Mecca at the time when the Prophet arose; but no trace of this or anything like it is found in really good and ancient authorities. We hear, indeed, of a Meccan hanging up a spoil of battle on the Kaʿba (Ibn Hishām, ed. Wüstenfeld, p. 431). Less credible is the story of an important document being deposited in that sanctuary (ibid. p. 230), for this looks like an instance of later usages being transferred to pre-Islamic times. But at all events this is quite a different thing from the hanging up of poetical manuscripts. To account for the disappearance of the Moʿallaqāt from the Kaʿba we are told, in a passage of late origin (De Sacy, *Chrestom.* ii. 480), that they were taken down at the capture of Mecca by the Prophet. But in that case we should expect some hint of the occurrence in the circumstantial biographies of the Prophet, and in the works on the history of Mecca; and we find no such thing. That a series of long poems was *written* at all at that remote period is improbable in the extreme. Up to a time when the art of writing had become far more general than it was before the spread of Islam, poems were never—or very rarely—written, with the exception, perhaps, of epistles in poetic form. The diffusion of poetry was exclusively committed to *oral* tradition. Moreover, it is quite inconceivable that there should have been either a gild or a private individual of such acknowledged taste, or of such influence, as to bring about a consensus of opinion in favour of certain poems. Think of the mortal offence which the canonization of one poet must have given to his rivals and their tribes. It was quite another thing for an individual to give his own private estimate of the respective merits of two poets who had appealed to him as umpire, or for a number of poets to appear at large gatherings, such as the fair of ʿOqāẓ (Okad) as candidates for the place of honour in the estimation of the throng which listened to their recitations. No better is the modifications of the legend, which we find, at a much later period, in the *Moqaddima* of Ibn Khaldūn (A.D. 1332–1406), who tells us that the poets themselves hung up their poems on the Kaʿba (ed. Paris iii. 357). In short, this legend, so often retailed by Arabs, and still more frequently by Europeans, must be entirely rejected.[1] The story is a pure fabrication based on the name "suspended." The word was taken in its literal sense; and as these poems were prized by many above all others in after times, the same opinion was attributed to "the [ancient] Arabs," who were supposed to have given effect to their verdict in the way already described. A somewhat simpler version, also given by Naḥḥās in the passage already cited, is as follows: "Most of the Arabs were accustomed to meet at ʿOqāẓ and recite verses; then, if the king was pleased with any poem, he said, 'Hang it up, and preserve it among my treasures.'" But, not to mention other difficulties, there was no king of all the Arabs; and it is hardly probable that any Arabian king attended the fair at ʿOqāẓ. The story that the poems were written in gold has evidently originated in the name "the golden poems" (literally "the gilded"), a figurative expression for excellence. We may interpret the designation "suspended" on the same principle. It seems to mean those (poems) which have been raised, on account of their value, to a specially honourable position. Another derivative of the same root is *ʿilq*, "precious thing." A clearer significance attaches to another name sometimes used for these poems—*assumūt*, "the strings of pearls." The comparison of artificially elaborated poems to these strings is extremely apt. Hence it became so popular that, even in ordinary prose, to speak in rhythmical form is called simply *naẓm*—"to string pearls."

[2] Excavation alone can supplement the scanty information which the present evidence furnishes. For a representation of a Moabite warrior (-god ?), see G. Perrot and C. Chipiez, *Art in Phoenicia*, ii. 45 seq.

[3] See W. R. Smith, *Religion of the Semites* (2nd ed.), which may be supplemented by the scattered gleanings in Clermont-Ganneau's *Recueil d'archéologie orientale*; and more especially by P. Antonin Jaussin's valuable monograph, *Coutumes des Arabes au pays de Moab* (Paris, 1908). (See also Hebrew Religion.)

[4] Ernst Frenkel, *An-Naḥḥās' Commentar zur Muʻallaqa des Imruul-Qais* (Halle, 1876), p. viii.

The selection of these seven poems can scarcely have been the work of the ancient Arabs at all. It is much more likely that we owe it to some connoisseur of a later date. Now Naḥḥās says expressly in the same passage: "The true view of the matter is this: when Ḥammād ar-Rāwiya (Ḥammād the Rhapsodist) saw how little men cared for poetry, he collected these seven pieces, urged people to study them, and said to them: 'These are the [poems] of renown.'" And this agrees with all our other information. Ḥammād (who lived in the first three quarters of the 8th century A.D.) was perhaps of all men the one who knew most Arabic poetry by heart. The recitation of poems was his profession. To such a rhapsodist the task of selection is in every way appropriate; and it may be assumed that he is responsible also for the somewhat fantastic title of "the suspended."

There is another fact which seems to speak in favour of Ḥammād as the compiler of this work. He was a Persian by descent, but a client of the Arab tribe, Bakr ibn Wāīl. For this reason, we may suppose, he not only received into the collection a poem of the famous poet Ṭarafa, of the tribe of Bakr, but also that of another Bakrite, Ḥārith, who, though not accounted a bard of the highest rank, had been a prominent chieftain; while his poem could serve as a counterpoise to another also received—the celebrated verses of Ḥārith's contemporary ʿAmr, chief of the Taghlib, the rival brethren of the Bakr. ʿAmr praises the Taghlib in glowing terms: Ḥārith, in a similar vein, extolls the Bakr—ancestors of Ḥammād's patrons. The collection of Ḥammād appears to have consisted of the same seven poems which are found in our modern editions, composed respectively by Amra'al-Qais, Ṭarafa, Zuhair, Labīd, ʿAntara ibn Shaddād, ʿAmr ibn Kulthūm, and Ḥārith ibn Ḥilliza. These are enumerated both by Ibn ʿAbd-Rabbihi, and, on the authority of the older philologists, by Naḥḥās; and all subsequent commentators seem to follow them. We have, however, evidence of the existence, at a very early period, of a slightly different arrangement. Certainly we cannot now say, on the testimony of the *Jamharat ashʿār al ʿArab*, that two of the most competent ancient authorities on Arabic poetry, Mofaḍḍal (d. *c.* 790) and Abū ʿUbaida (d. A.D. 824, at a great age), had already assigned to the "Seven" (viz. "the seven Moʿallaqāt") a poem each of Nābigha and Aʿshā in place of those of ʿAntara and Ḥārith. For meanwhile it has been discovered that the compiler of the above-mentioned work—who, in order to deceive the reader, issued it under a false name—is absolutely untrustworthy. But the learned Ibn Qotaiba (9th century A.D.), in his book *Of Poetry and Poets*, mentions as belonging to the "Seven" not only the poem of ʿAmr, which has invariably been reckoned among the Moʿallaqāt (ed. de Goeje, p. 120), but also a poem of ʿAbīd ibn Abraṣ (ibid. 144). In place of which poem he read this we do not know; and we are equally ignorant as to whether he counted other pieces than those indicated above among the seven.

Now Nābigha and Aʿshā enjoyed greater celebrity than any of the poets represented in the Moʿallaqāt, with the exception of Amra'al-Qais, and it is therefore not surprising that scholars, of a somewhat later date, appended a poem by each of these to the Moʿallaqāt, without intending by this to make them an integral part of that work. This is clear, for instance, from the introductory words of Tibrīzī (d. A.D. 1109) to his commentary on the Moʿallaqāt. Appended to this he gives a commentary to a poem of Nābigha, to one of Aʿshā, and moreover one to that poem of ʿAbīd which, as we have just seen, Ibn Qotaiba had counted among the seven. It is a pure misunderstanding when Ibn Khaldūn (*loc. cit.*) speaks of *nine* Moʿallaqāt; and we ought hardly to lay any stress on the fact that he mentions not only Nābigha and Aʿshā, but also ʿAlqama, as Moʿallaqa-poets. He was probably led to this by a delusive recollection of the Collection of the "Six Poets," in which were included these three, together with the three Moʿallaqa-poets, Amra'al-Qais, Zuhair and Ṭarafa.

The lives of these poets were spread over a period of more than a hundred years. The earliest of the seven was AMRA'AL-QAIS (*q.v.*), regarded by many as the most illustrious of Arabian poets. His exact date cannot be determined; but probably the best part of his career fell within the midst of the 6th century. He was a scion of the royal house of the tribe Kinda, which lost its power at the death of King Ḥārith ibn ʿAmr in the year 529.[1] The poet's royal father, Ḥojr, by some accounts a son of this Ḥārith, was killed by a Bedouin tribe, the Banū Asad. The son led an adventurous life as a refugee, now with one tribe, now with another, and appears to have died young. The anecdotes related of him—which, however, are very untrustworthy in detail—as well as his poems, imply that the glorious memory of his house and the hatred it inspired were still comparatively fresh, and therefore recent. A contemporary of Amra'al-Qais was **ʿAbīd ibn Abraṣ**, one poem of whose, as we have seen, is by some authorities reckoned among the collection. He belonged to the Banū Asad, and is fond of vaunting the heroic dead of his tribe—the murder of Ḥojr— in opposition to the victim's son, the great poet.

---

[1] Doubts had already been expressed by various scholars, when Hengstenberg—rigid conservative as he was in theology—openly challenged it, and Sprenger (*Das Leben des Mohammad*, i. 14, Berlin, 1861) declared it a fable. Since then it has been controverted at length in Nöldeke's *Beiträge zur Kenntniss der Poesie der alten Araber* (Hanover, 1864), p. xvii. sqq. Ahlwardt concurs in this conclusion; see his *Bemerkungen über die Aechtheit der alten arabischen Gedichte* (1872), pp. 25 seq.

The Moʿallaqa of **ʿAmr** hurls defiance against the king of Ḥīra, ʿAmr son of Mundhir, who reigned from the summer of 554 till 568 or 569, and was afterwards slain by our poet.[2] This prince is also addressed by **Ḥārith** in his Moʿallaqa. Of **Ṭarafa**, who is said to have attained no great age, a few satirical verses have been preserved, directed against this same king. This agrees with the fact that a grandson of the Qais ibn Khālid, mentioned as a rich and influential man in Ṭarafa's Moʿallaqa (v. 80 or 81), figured at the time of the battle of Dhū-Qār, in which the tribe Bakr routed a Persian army. This battle falls between A.D. 604 and 610.[3]

The Moʿallaqa of **ʿAntara** and that of **Zuhair** contain allusions to the feuds of the kindred tribes ʿAbs and Dhobyān. Famous as these contests were, their time cannot accurately be ascertained. But the date of the two poets can be approximately determined from other data. Kaʿb, son of Zuhair, composed first a satire, and then, in the year 630, a eulogy on the Prophet; another son, Bujair, had begun, somewhat sooner, to celebrate Mahomet. ʿAntara killed the grandfather of Aḥnaf ibn Qais, who died at an advanced age in A.D. 686 or 687; he outlived ʿAbdallāh ibn Ṣimma, whose brother Duraid was a very old man when he fell in battle against the Prophet (early in A.D. 630); and he had communications with Ward, whose son, the poet ʿOrwa, may perhaps have survived the flight of Mahomet to Medina. From all these indications we may place the productive period of both poets in the end of the 6th century. The historical background of ʿAntara's Moʿallaqa lies somewhat earlier than that of Zuhair's.

To the same period appears to belong the poem of **ʿAlqama**, which, as we have seen, Ibn Khaldūn reckons amongst the Mo ʿallaqāt. This too is certainly the date of **Nābigha**, who was one of the most distinguished of Arabic poets. For in the poem often reckoned as a Moʿallaqa, as in many others, he addresses himself to Noʿmān, king of Ḥīra, who reigned in the two last decades of the 6th century. The same king is mentioned as a contemporary in one of ʿAlqama's poems.

The poem of **Aʿsha**, sometimes added to the Moʿallaqāt, contains an allusion to the battle of Dhū Qār (under the name "Battle of Ḥinw," v. 62). This poet, not less famous than Nābigha, lived to compose a poem in honour of Mahomet, and died not long before A.D. 630.

Labīd is the only one of these poets who embraced Islam. His Moʿallaqa, however, like almost all his other poetical works, belongs to the Pagan period. He is said to have lived till 661, or even later; certainly it is true of him, what is asserted with less likelihood of several others of these poets, that he lived to a ripe old age.

The seven Moʿallaqāt, and also the poems appended to them, represent almost every type of ancient Arabian poetry in its excellences and its weaknesses. In order rightly to appreciate these, we must translate ourselves into the world of the Bedouin, and seek to realize the peculiar conditions of his life, together with the views and thoughts resulting from those conditions. In the Moʿallaqa of Ṭarafa we are repelled by the long, anatomically exact description of his camel; but such a description had an extraordinary charm of its own for the Bedouins, every man of whom was a perfect connoisseur on this subject down to the minutest points; and the remaining parts of the poem, together with the other extant fragments of his songs, show that Ṭarafa had a real poetic gift. In the Moʿallaqāt of ʿAmr and Ḥārith, for the preservation of which we are especially grateful to the compiler, we can read the haughty spirit of the powerful chieftains, boastfully celebrating the splendours of their tribe. These two poems have also a certain historical importance. The song of Zuhair contains the practical wisdom of a sober man of the world. The other poems are fairly typical examples of the customary *qaṣīda*, the long poem of ancient Arabia, and bring before us the various phases of Bedouin life. But even here we have differences. In the Moʿallaqa of ʿAntara, whose heroic temperament had overcome the scorn with which the son of a black slave-mother was regarded by the Bedouins, there predominates a warlike spirit, which plays practically no part in the song of Labīd.

It is a phenomenon which deserves the fullest recognition, that the needy inhabitants of a barren country should thus have produced an artistic poetry distinguished by so high a degree of uniformity. Even the extraordinary strict metrical system, observed by poets who had no inkling of theory and no knowledge of an alphabet, excites surprise. In the most ancient poems the metrical form is as scrupulously regarded as in later compositions. The only poem which shows unusual metrical freedom is the above-mentioned song of ʿAbīd. It is, however, remarkable that ʿAbīd's contemporary Amra'al-Qais, in a poem which in other respects also exhibits certain coincidences with that of ʿAbīd (No. 55, ed. Ahlwardt), presents himself considerable licence in the use of the very same metre—one which, moreover, is extremely rare in the ancient period. Presumably, the violent deviations from the *schema* in ʿAbīd are due simply to incorrect transmission by compilers who failed to grasp the metre. The other poems ascribed to ʿAbīd, together with all the rest attributed to Amra'al-Qais, are constructed in precise accord with the metrical canons. It is necessary always to bear in mind that these ancient poems, which for a century or more were preserved by oral tradition alone, have reached us in a much mutilated condition. Fortunately, there was a class of men who made it their special business to learn by rote the works either of a single poet or of several. The poets themselves used the services of these rhapsodists (rāwī). The last representative of this class is Ḥammād, to whom is attributed the collection of the Moʿallaqāt; but he, at the same time, marks the transition of the rhapsodist to the critic and scholar. The most favourable opinion of these rhapsodists would require us to make allowance for occasional mistakes: expressions would be transposed, the order of verses disarranged, passages omitted, and probably portions of different poems pieced together. It is clear, however, that Ḥammād dealt in the most arbitrary fashion with the enormous quantity of poetry which he professed to know thoroughly. The seven Moʿallaqāt are indeed free from the suspicion of forgery, but even in them the text is frequently altered and many verses are transposed. The loose structure of Arabic poems was extremely favourable to such alterations. Some of the Mo'allaqāt have several preambles: so, especially, that of ʿAmr, the first eight verses of which belong not to the poem, but to another poet. Elsewhere, also, we find spurious verses in the Moʿallaqāt. Some of these poems, which have been handed down to us in other exemplars besides the collection itself, exhibit great divergences both in the order and number of the verses and in textual details. This is particularly the case with the oldest Moʿallaqa—that of Amra'al-Qais—the critical treatment of which is a problem of such extreme difficulty that only an approximate solution can ever be reached. The variations of the text, outside the Moʿallaqāt collection, have here and there exercised an influence on the text of that collection. It would be well if our manuscripts at least gave the Moʿallaqāt in the exact form of Ḥammād's days. The best text—in fact, we may say, a really good text—is that of the latest Moʿallaqa, the song of Labīd.

[3] Ibid. p. 311.

The Moʿallaqāt exist in many manuscripts, some with old commentaries, of which a few are valuable. They have also been several times printed. Especial mention is due to the edition of Charles (afterwards Sir Charles) Lyall with the commentary of *Tibrīzī* (Calcutta, 1894). Attempts to translate these poems, verse for verse, in poetical form, could scarcely have a happy result. The strangeness, both of the expression and of the subjects, only admits of a paraphrastic version for large portions, unless the sense is to be entirely obliterated. An attempt at such a translation, in conjunction with a commentary based on the principles of modern science, has been made by the present author: "Fünf Moʿallaqāt übersetzt und erklärt," in the *Sitzungsberichte der kais. Akad. d. Wiss. in Wien. Philos.-hist. Classe.* Bde. cxl.–cxiv. A supplement to this is formed by an article, by Dr Bernh. Geiger, on the Moʿallaqa of Ṭarafa, in the *Wiener Zeitschrift für die Kunde des Morgenlands*, xix. 323 sqq. See further the separate articles on the seven poets.

(Th. N.)

MOAT, a ditch filled with water surrounding a castle, town or other fortified place for purposes of defence. The word is taken from the O. Fr. *mote*, or *motte*, a mound or embankment of earth used as a means of defence; the transition in meaning from the heap of earth to the trench left by excavating the earth is parallel with the similar interchange of meaning in dike and ditch (see Dike). In mod. Fr. *motte* means a lump or clod of earth. The word is probably of Teutonic origin, and may be connected with Eng. "mud." (See Fortification and Siegecraft.)

MOB. (1) A disorderly crowd, a rabble, also a contemptuous name for the common people, the lower orders, the Greek ὄχλος, (whence "ochlocracy," mob-rule). The word is a shortened form of Lat. *mobile* (*sc. vulgus*), the movable or mutable emotional, easily stirred crowd. "Mobile" in the sense of rabble was used in the 17th century, and was still used after the shortened form, for some time considered a vulgarism, had become common. Thus Addison (*Spectator*, No. 135) writes, "It is perhaps this humour of speaking no more than we needs must which has so miserably curtailed some of our words. . . . I dare not answer that 'mob' . . . 'incog.' and the like will not in time be looked at as part of our tongue." Roger North's *Examen*, vii., 574 (1740), dates the beginning of the use of the shortened form "mob." "I may note that the rabble first changed their title and were called the 'mob' in the assemblies of this club. It was their beast of burden, and called first *mobile vulgus*, but fell naturally into the contraction of one syllable, and ever since is become proper English." The club alluded to is the Green Ribbon Club (*q.v.*), and the date would be about 1680. (2) A kind of head-dress for women, usually called a "mob cap," worn during the 18th and early part of the 19th centuries. It was a large cap covering all the hair, with a bag-shaped crown, a broad band and frilled edge. It seems to have been originally an article of wear for the mornings. It is probably connected with words such as "mop," "mab," meaning untidy, *négligé*.

MOBERLY, GEORGE (1803–1885), English divine, was born on the 10th of October 1803, and educated at Winchester and Balliol. After a distinguished academic career he became head master of Winchester in 1835. This post he resigned in 1866, and retired to Brightstone Rectory, Isle of Wight. Mr. Gladstone, however, in 1869 called him to be bishop of Salisbury, in which see he kept up the traditions of his predecessors, Bishops Hamilton and Denison, his chief addition being the summoning of a diocesan synod. Though Moberly left Oxford at the beginning of the Oxford movement, he fell under its influence: the more so that at Winchester he formed a most intimate friendship with Keble, spending several weeks every year at Otterbourne, the next parish to Hursley. Moberly, however, retained his independence of thought, and in 1872 he astonished his High Church friends by joining in the movement for the disuse of the damnatory clauses in the Athanasian Creed. His chief contribution to theology is his Bampton Lectures of 1868, on *The Administration of the Holy Spirit in the Body of Christ.* He died on the 6th of July 1885.

MOBERLY, ROBERT CAMPBELL (1845–1903), English theologian, was born on the 26th of July 1845. He was the son of George Moberly, bishop of Salisbury, and faithfully maintained the traditions of his father's teaching. Educated at Winchester and New College, Oxford, he was appointed senior student of Christ Church in 1867 and tutor in 1869. In 1876 he went out with Bishop Copleston to Ceylon for six months. After his return he became the first head of St Stephen's House, Oxford (1876–1878), and then, after presiding for two years over the Theological College at Salisbury, where he acted as his father's chaplain, he accepted the college living of Great Budworth in Cheshire in 1880, and the same year married Alice, the daughter of his father's predecessor, Walter Kerr Hamilton. In 1892 Lord Salisbury made him Regius Professor of Pastoral Theology of Oxford; and after a long period of delicate health he died at Christ Church on the 8th of June 1903. His chief writings were: An essay in *Lux Mundi* on "The Incarnation as the Basis of Dogma" (1889); a paper, *Belief in a Personal God* (1891); *Reason and Religion* (1896), a protest against the limitation of the reason to the understanding; *Ministerial Priesthood* (1897); and *Atonement and Personality* (1901). In this last work, by which he is chiefly known, he aimed at presenting an explanation and a vindication of the doctrine of the Atonement by the help of the conception of personality. Rejecting the retributive view of punishment, he describes the sufferings of Christ as those of the perfect "Penitent," and finds their expiatory value to lie in the Person of the Sufferer, the God-Man.

MOBERLY, a city of Randolph county, Missouri, U.S.A., in the north central part of the state, about 130 m. E. by N. of Kansas City. Pop. (1890), 8215; (1900), 8012, (923 negroes); (1910), 10,923. It is served by the Missouri, Kansas & Texas and the Wabash railways, and is a division headquarters of the latter. The city is regularly laid out on a level prairie site. There are two public parks, a Carnegie library, a commercial college, a Y.M.C.A. building, and a hospital maintained by the Wabash Employees Hospital Association. The most important industrial establishments are the large machine shops (established here in 1872) of the Wabash railway. Moberly was platted in 1866, was incorporated as a town and became the county-seat in 1868, and in 1873 secured a special city charter, which it surrendered in 1889 for city status under the general statute.

MOBILE, a city and the county-seat of Mobile county, Alabama, U.S.A., in the S.W. part of the state, at the mouth of Mobile River, and the head of Mobile Bay. Pop. (1890), 31,076; (1900), 38,469, of whom 17,045 were negroes and 2111 foreign-born (562 German, 492 Irish, 202 English); (1910 census), 51,521. It is served by the Southern, the Louisville & Nashville, the Mobile & Ohio, the Mobile, Jackson & Kansas City, and the Tombigbee Valley railways; by steamboat lines to ports in Europe, Cuba, Mexico, Central America (especially Panama) and South America; by a coastwise steamboat line to New York; and by river boats on a river system embracing nearly 2000 m. of navigable waters in Alabama, Mississippi, and Georgia. The city occupies about 17 sq. m. of a sandy plain, which rises gradually from a low water front along the river to a range of hills a few miles to the westward. Among the principal buildings are the customs-house and post-office, the court-house, the Battle House (a hotel), the United States marine hospital, the city hospital, the Providence infirmary, Barton Academy (a part of the public school system), a Young Men's Christian Association building, St Joseph's church (Roman Catholic), the cathedral of the Immaculate Conception, the Van Antwerp office building, and the southern market and armoury. Mobile is the see of a Roman Catholic bishopric and the headquarters of the United States district court for the southern district of Alabama. In the city are a public library; the departments of medicine and pharmacy of the university of Alabama; the academy of the Visitation, and the

Immaculate Conception school, both for girls and both Roman Catholic; the Convent of Mercy; the Emerson normal and industrial school (for negroes), McGill Institute, the University military school, and the Mobile military institute; and 5 m. from Mobile, at Spring Hill, is Spring Hill college (Roman Catholic, founded in 1830, chartered 1836), controlled by the Jesuits. There is an annual celebration in Mobile on Mardi Gras (Shrove Tuesday), conducted by the Order of Myths and the Mystics, two social organizations, successors of the Cowbellion de Rakin Society, which was organized in 1830 and long conducted a somewhat similar celebration annually on New Year's Eve.

Mobile is the only seaport of Alabama. In 1826 the channel from it to the Gulf, about 30 m. distant, had a minimum depth of only 5½ ft. through Choctaw Pass and 8 ft. through Dog River bar; but subsequently the channel has been greatly improved by the United States government, and in June 1908[1] vessels drawing 23 and 24 ft. could pass at low-water to the mouth of Chickasaw Creek above the city. While the channel was still shallow, and rapidly growing railway systems were serving other ports, much foreign commerce was lost to Mobile, the value of the exports falling off from $12,784,171 in 1877 to $3,258,605 in 1882, and the value of the imports, during the same period, from $648,404 to $396,573; but after the improvement of the channel the value of the exports increased from $8,140,502 in 1897 to $26,815,279 in 1908, and the value of the imports rose from $956,712 in 1897 to $4,242,169 in 1908. The foreign commerce consists largely in the export of cotton, lumber, timber, cotton-seed oil, coal, provisions and clothing, and in the import of tropical fruits (especially bananas), sisal grass, coffee, mahogany, asphalt, and manganese and sulphur ores. Vegetables, particularly beans and cabbage, and small fruits are grown extensively in the vicinity, and the city has an important domestic trade in market-garden produce, fish and oysters, hardware, dry goods, grain and groceries. In manufacturing Mobile was second (Birmingham being first) among the cities of the state in 1905, when the value of the factory product was $4,942,331, 41·8% more than in 1900. In 1905 it ranked first in the state in the value of fertilizer, lumber and timber, and in the construction of railway cars; and the manufacture of flour and grist mill products and machinery for lumber mills were important industries.

Founded by Pierre Lemoyne, Sieur d'Iberville (1661–1706), and his brother Jean Baptiste Lemoyne, Sieur de Bienville (1680–1768), in 1702, Mobile[2] was the capital of the French province of Louisiana until 1720, when the seat of government was transferred to Biloxi, in the present Mississippi. The original settlement was at Twenty-seven Mile Bluff, about 20 m. above the present site, to which it was removed in 1710 as a consequence of floods in 1709. By the Treaty of Paris (1763) Mobile, as a part of Louisiana east of the Mississippi, was ceded to Great Britain; but on the 14th of March 1780 it was captured by a Spanish force under Don Bernardo de Galvez (1755–1786), the governor at New Orleans, and Spain was confirmed in its possession by the treaty of 1783. Spanish civil institutions were introduced, and new names, such as Conception, St Emanuel and St Joseph, which still survive, were given to the streets. Yet neither the English nor the Spanish occupation made any substantial change in the tone of the place or the habits of its people, even the negroes holding to their French jargon. The alliance between Great Britain and Spain, at the outbreak of the war of 1812, gave Mobile strategic importance for the military operations in the south-west. Hence, on the 15th of April 1813 General James Wilkinson, acting on President James Madison's instructions, which were based on the claim that Mobile was a part of Louisiana sold by France to the United States in 1803, seized Mobile for the United States. In August 1814 General Andrew Jackson made Mobile his headquarters. He repaired Fort Bowyer, on Mobile Point at the mouth of the bay, and garrisoned it just in time for it to resist attack by the British on the 15th of September. On the 11th of February 1815, forty-two days after peace had been declared and thirty-four days after the battle of New Orleans, a British force captured Fort Bowyer; but it made no move against Mobile, and withdrew on the 1st of April. Now began the Americanization of Mobile, a tide of immigration from the up-country setting in and rapidly changing the character of the place, which had previously been distinctly French. A town charter had been granted by the territorial legislature of Mississippi on the 20th of January 1814, and an interesting feature under the town government was the "tariff for bakers," which fixed the weight of loaves of bread in accordance with the price of flour. A city charter, dated the 17th of December 1819, was granted by the first state legislature of Alabama, and Mobile became the commercial emporium for Alabama and Mississippi, its cotton exports increasing from 7000 bales in 1818 to 100,000 in 1830 and 450,000 in 1840. In 1826 Barton Academy, still one of the landmarks of the city, was built; but it was not until 1852 that common schools were opened in Mobile county. Branches of the United States Bank and of the State bank were established at Mobile, and in the panic of 1837 the Bank of Mobile was one of the few banks in the United States that did not suspend payment. The Mobile & Ohio railroad, begun in 1848, provided ampler communication with the Mississippi valley, and Mobile's export of cotton rose to 1,000,000 bales in 1861.

During the Civil War Mobile was an important seaport of the Confederacy. A Federal blockade was begun as early as the 26th of May 1861, but trade with West Indian and European ports was continued by a line of swift vessels, which regularly escaped the blockading squadron. On the 5th of August 1864 Admiral David G. Farragut (*q.v.*), with a Federal fleet of four iron monitors, seven wooden sloops of war, and several gunboats, entered the channel by passing the Confederate defences, Fort Gaines on Dauphin Island and Fort Morgan occupying the site of old Fort Bowyer on Mobile Point, captured the formidable Confederate ironclad ram "Tennessee," destroyed one gunboat and drove another aground. One of the Federal monitors, the "Tecumseh," was destroyed by torpedoes. The Confederate fleet was commanded by Admiral Franklin Buchanan (1800–1874). Fort Gaines surrendered on the 7th, and Fort Morgan on the 23rd of the same month. In the spring of 1865 General E. R. S. Canby (1819–1873), with a Federal force of about 45,000, laid siege to Fort Blakely and Spanish Fort, on the east side of the bay (opposite the city), defended by General Randall L. Gibson (1832–1892) with 5000 men. After twenty-five days of resistance the Confederates evacuated the fortifications and then the city, the Federals entering on the 12th of April 1865. Losses from railway enterprises and the panic of 1873 resulted in the bankruptcy of the municipality in 1879, whereupon its charter was vacated, its property vested in certain trustees acting under the Chancery Court to adjust its debt, and a municipal government under the name of Port of Mobile succeeded the city of Mobile until 1887, when the latter was again chartered. On the 27th of September 1906 Mobile was swept by a hurricane, which destroyed property valued at $5,000,000 or more.

See Peter J. Hamilton, *Colonial Mobile* (Boston, 1897); and a chapter by the same writer in L. P. Powell's *Historic Towns of the Southern States* (New York, 1900).

MÖBIUS, AUGUST FERDINAND (1790–1868), German astronomer and mathematician, was born at Schulpforta on the 17th of November 1790. At Leipzig, Göttingen and Halle he studied for four years, ultimately devoting himself to mathematics and astronomy. In 1815 he settled at Leipzig as privatdocent, and the next year became extraordinary professor of astronomy in connexion with the university. Later he was chosen director of the university observatory, which was erected (1818–1821) under his superintendence. In 1844 he was elected ordinary professor of higher mechanics and astronomy, a position which he held till his death on the 26th of September 1868. His doctor's dissertation, *De computandis occultationibus fixarum per planetas* (Leipzig, 1815), established his reputation as a theoretical astronomer. *Die Hauptsätze der Astronomie* (1836), *Die Elemente der Mechanik des Himmels* (1843), may be noted amongst his other purely astronomical publications. Of more general interest, however, are his labours in pure mathematics, which appear for the most part in *Crelle's Journal* from 1828 to 1858. These papers are chiefly geometrical, many of them being developments and applications of the methods laid down in his great work, *Der barycentrische Calcul* (Leipzig, 1827), which, as the name implies, is based upon the properties of the mean point or centre of mass (see ALGEBRA: *Universal*). This work abounds in suggestions and foreshadowings of some of the most striking discoveries in more recent times—such, for example, as are contained in H. Grassmann's *Ausdehnungslehre* and Sir W. R. Hamilton's *Quaternions*. Möbius must be regarded as one of the leaders in the introduction of the powerful methods of modern projective geometry.

---

[1] Between 1826 and 1908 the Federal government expended $5,148,179 on the improvement of the harbour. The bar channel also has been improved.

[2] The city was named from the Mobile or Maubila Indians, a Muskhogean tribe, now extinct, who occupied the neighbouring region and were Christianized by the French.

His *Gesammelten Werke* have been published in four volumes at Leipzig (1885–1887).

MOCATTA, FREDERICK DAVID (1828–1905), English Jewish philanthropist, was a member of the London financial firm, Mocatta and Goldsmid, but retired from business in 1874 and devoted himself to works of public and private benevolence. Besides this he was a patron of learning and himself an author of historical works, the chief of which was *The Jews and the Inquisition*. On occasion of his 70th birthday, he was presented with a testimonial from more than 200 philanthropic and literary institutions. The Anglo-Jewish Historical Exhibition (1887) owed its inception to him. He bequeathed his fine library to the Jewish Historical Society of England, of which he was at one time president. This library formed the basis of the collections which are now included in the Mocatta Library and Museum, founded in his memory, and located at the University of London (University College, Gower Street).

MOCCASIN (a North-American Indian word, of which the spelling and pronunciation vary in different dialects), a shoe made of deerskin or other soft leather. It is made in one piece; the sole is soft and flexible and the upper part is often adorned with embroidery, beading or other ornament. It is the footwear of the North American Indian tribes and is also worn by hunters, traders and settlers. In botany, the lady's slipper is known in the United States of America, as the "moccasin flower," from its resemblance to a shoe or moccasin. The name moccasin is also given to a venomous snake, found as far north as North Carolina and westward to the Rocky Mountains, and popularly called "cottonmouth," from the white rim around the mouth. It belongs to the family *Crotalidae*, species *Ancistrodon* (or *Cenchris*) *piscivorus*, is about two feet long, and is often found in marshy land. It is sometimes called the *water moccasin* to distinguish it from the upland moccasin (*Ancistrodon contortrix* or *atrofuscus*), which is commonly called "copperhead" and is found further north in dry and mountainous regions. The name is possibly a distinct word of which the origin has not been traced.

MOCENIGO, the name of a noble and ancient Venetian family which gave many doges, statesmen and soldiers to the republic. TOMMASO MOCENIGO (1343–1423) commanded the crusading fleet in the expedition to Nicopolis in 1396, and also won battles against the Genoese. While he was Venetian ambassador at Cremona he was elected doge (1414), and he escaped in secret, fearing that he might be held a prisoner by Gabrino Fondolo, tyrant of that city. He made peace with the Turkish sultan, but when hostilities broke out afresh his fleet defeated that of the Turks at Gallipoli. During his reign the patriarch of Aquileia was forced to cede his territories to the republic (1420), which also acquired Friuli and Dalmatia. Tommaso greatly encouraged commerce, reconstructed the ducal palace and commenced the library. PIETRO MOCENIGO, doge from 1474 to 1476, was one of the greatest Venetian admirals, and revived the fortunes of his country's navy, which had fallen very low after the defeat at Negropont in 1470. In 1472 he captured and destroyed Smyrna; the following year he placed Catherine Cornaro, queen of Cyprus, under Venetian protection, and by that means the republic obtained possession of the island in 1475. He then defeated the Turks who were besieging Scutari, but he there contracted an illness of which he died. GIOVANNI MOCENIGO, Pietro's brother, who was doge from 1478 to 1485, fought against Mohammed II. and Ercole I., duke of Ferrara, from whom he recaptured Rovigo and the Polesine. LUIGI MOCENIGO was doge from 1570 to 1577. During his reign Venice lost the fortresses Nicosia and Famagosta in Cyprus. He took part in the battle of Lepanto, but after the loss of Cyprus he was forced to make peace with the Turks and to hand them back his conquests. ANDREA MOCENIGO, who flourished in the 15th and 16th centuries, was a senator of the republic and a historian; he composed a work on the league of Cambrai entitled *Belli memorabilis Cameracensis adversus Venetos historiae libri vi.* (Venice, 1525). Another LUIGI MOCENIGO was doge from 1700 to 1709, and his brother SEBASTIANO from 1722 to 1732. ALVISE MOCENIGO (1701–1778), who was doge from 1763 until his death, restricted the privileges of the clergy, and in consequence came into bitter conflict with Pope Clement XIII.

MOCHA STONE, a name applied to chalcedony with dendritic markings, said to have been obtained originally from Mocha in Arabia. The markings which sometimes simulate with curious fidelity the form of miniature trees and shrubs, are caused by the infiltration of solutions carrying iron and manganese, which are deposited as thin films of oxide along the cracks of the stone, producing black, brown or red dendrites, effectively disposed on a ground of grey or white chalcedony. Most of the Mocha stones of commerce are obtained from India, where they are found among the agate-pebbles resulting from the disintegration of the trap rocks of the Deccan. In recent years the formation of dendrites has been artificially effected at the agate-works of Oberstein, so as to imitate the true Mocha stones.

MOCK, an adjective meaning sham, feigned, spurious, falsely imitative. As a verb it means to deride or imitate contemptuously. The derivation of O. Fr. *mocquer*, mod. *moquer*; Ital. *moccare*, from which the English word is adopted, is disputed. Some authorities refer it to Ger. *mucken*, *mucksen*, to growl, grumble, which is probably echoic in origin; others to a supposed Late Lat. *muccare*, formed from *mucus*—mucus, in the sense of "to wipe the nose at."

MOCKING-BIRD, or MOCK-BIRD (as W. Charleton, J. Ray and M. Catesby called it), the popular name of birds belonging to the American sub-family *Miminae* of the thrushes, *Turdidae*, differing by having the tarsus scutellate in front, while the typical thrushes have it covered by a single horny plate. *Mimus polyglottus*, the northern mocking-bird, inhabits the southern part of the United States, being in the north only a summer visitant; it breeds rarely in New England, is seldom found north of the 38th parallel, and migrates to the south in winter, passing that season in the Gulf States and Mexico. It appears to be less numerous on the western side of the Alleghanies, though found in suitable localities across the continent to the Pacific coast, but seldom farther north than Virginia and southern Illinois, and it is said to be common in Kansas. J. J. Audubon states that the mocking-birds which are resident all the year round in Louisiana attack their travelled brethren on the return of the latter from the north in autumn. The names of the species, both English and scientific, have been bestowed from its capacity of successfully imitating the cry of many other birds, to say nothing of other sounds, in addition to uttering notes of its own which possess a varied range and liquid fullness of tone that are unequalled, according to its admirers, even by those of the nightingale (*q.v.*).

Plain in plumage, being greyish brown above and dull white below, while its quills are dingy black, variegated with white, there is little about the mocking-bird's appearance beyond its graceful form to recommend it; but the lively gesticulations it exhibits are very attractive, and therein its European rival in melody is far surpassed, for the cock-bird mounts aloft in rapid circling flight, and, alighting on a conspicuous perch, pours forth his ever-changing song to the delight of all listeners; while his actions in attendance on his mate are playfully demonstrative and equally interest the observer. The mocking-bird is moreover of familiar habits, haunting the neighbourhood of houses, and is therefore a general favourite. The nest is placed with little regard to concealment, and is not distinguished by much care in its construction. The eggs, from three to six in number, are of a pale bluish-green, blotched and spotted with light yellowish-brown. They, as well as the young, are much sought after by snakes, but the parents are often successful in repelling these deadly enemies, and are always ready to wage war against any intruder on their precincts, be it man, cat or hawk. Their food is various, consisting of berries, seeds and insects.

Some twelve or fourteen other species of *Mimus* have been recognized, mostly from South America; but *M. orpheus* seems to be common to some of the Greater Antilles, and *M. hilli* is peculiar to Jamaica, while the Bahamas have a local race in *M. bahamensis.* The so-called mountain mocking-bird (*Oreoscoptes montanus*) is a form not very distant from *Mimus*; but it inhabits exclusively the plains overgrown with sage-brush (*Artemisia*) of the interior tableland of North America, and is not at all imitative in its notes, so that it is an instance of a misnomer. Of the various other genera allied to *Mimus*, the best known are the thrashers (genus *Harporhynchus*) of which six or eight species are found in North America, which are thrush-like and shy in their habits and do not mimic; and the cat-bird (*Galeoscoptes carolinensis*), which in addition to having an attractive song, utters clucks, whistles and mewing sounds. The sooty-grey colour that, deepening into blackish-brown on the crown and quills, pervades the whole of its plumage—the lower tail-coverts, which are of a deep chestnut, excepted—renders it a conspicuous object; and though, for some reason or other, far from being a favourite, it is always willing when undisturbed to become intimate with men's abodes. It has a much wider range on the American continent than the mocking-bird, and is one of the few species that are resident in Bermuda, while on more than one occasion it is said to have appeared in Europe.

The name mocking-bird, or more frequently mock-nightingale, is in England occasionally given to some of the warblers (*q.v.*), especially the blackcap (*Sylvia atricapilla*), and the sedge-bird (*Acrocephalus schoenobaenus*). In India and Australia the same name is sometimes applied to other species. (A. N.)

MODEL (O. Fr. *modelle*, mod. *modèle*; It. *modello*, pattern, mould; from Lat. *modus*, measure, standard), a tangible representation, whether the size be equal, or greater, or smaller, of an object which is either in actual existence, or has to be constructed in fact or in thought. More generally it denotes a thing, whether actually existing or only mentally conceived of, whose properties are to be copied. In foundries, the object of which a cast is to be taken, whether it be for engineering or artistic purposes, is usually first formed of some easily workable material, generally wood. The form of this model is then reproduced in clay or plaster, and into the mould thus obtained the molten metal is poured. The sculptor first makes a model of the object he wishes to chisel in some plastic material such as wax, ingenious and complicated contrivances being employed to transfer this wax model, true to nature, to the stone in which the final work is to be executed. In anatomy and physiology, models are specially employed as aids in teaching and study, and the method of *moulage* or chromoplastic yields excellent impressions of living organisms, and enables anatomical and medical preparations to be copied both in form and colour. A special method is also in use for making plastic models of microscopic and minute microscopic objects. That their internal nature and structure may be more readily studied, these are divided by numerous parallel transverse cuts, by means of a microtome, into exceedingly thin sections. Each of these shavings is then modelled on an enlarged scale in wax or pulp plates, which are fixed together to form a reproduction of the object.

Representation in Thought.

Models in the mathematical, physical and mechanical sciences are of the greatest importance. Long ago philosophy perceived the essence of our process of thought to lie in the fact that we attach to the various real objects around us particular physical attributes—our concepts—and by means of these try to represent the objects to our minds. Such views were formerly regarded by mathematicians and physicists as nothing more than unfertile speculations, but in more recent times they have been brought by J. C. Maxwell, H. v. Helmholtz, E. Mach, H. Hertz and many others into intimate relation with the whole body of mathematical and physical theory. On this view our thoughts stand to things in the same relation as models to the objects they represent. The essence of the process is the attachment of one concept having a definite content to each thing, but without implying complete similarity between thing and thought; for naturally we can know but little of the resemblance of our thoughts to the things to which we attach them. What resemblance there is lies principally in the nature of the connexion, the correlation being analogous to that which obtains between thought and language, language and writing, the notes on the stave and musical sounds, &c. Here, of course, the symbolization of the thing is the important point, though, where feasible, the utmost possible correspondence is sought between the two—the musical scale, for example, being imitated by placing the notes higher or lower. When, therefore, we endeavour to assist our conceptions of space by figures, by the methods of descriptive geometry, and by various thread and object models; our topography by plans, charts and globes; and our mechanical and physical ideas by kinematic models—we are simply extending and continuing the principle by means of which we comprehend objects in thought and represent them in language or writing. In precisely the same way the microscope or telescope forms a continuation and multiplication of the lenses of the eye; and the notebook represents an external expansion of the same process which the memory brings about by purely internal means. There is also an obvious parallelism with representation by means of models when we express longitude, mileage, temperature, &c., by numbers, which should be looked upon as arithmetical analogies. Of a kindred character is the representation of distances by straight lines, of the course of events in time by curves, &c. Still, neither in this case nor in that of maps, charts, musical notes, figures, &c., can we legitimately speak of models, for these always involve a concrete spatial analogy in three dimensions.

So long as the volume of matter to be dealt with in science was insignificant, the need for the employment of models was naturally less imperative; indeed, there are self-evident advantages in comprehending things without resort to complicated models, which are difficult to make, and cannot be altered and adapted to extremely varied conditions so readily as can the easily adjusted symbols of thought, conception and calculation. Yet as the facts of science increased in number, the greatest economy of effort had to be observed in comprehending them and in conveying them to others; and the firm establishment of ocular demonstration was inevitable in view of its enormous superiority over purely abstract symbolism for the rapid and complete exhibition of complicated relations. At the present time it is desirable, on the one hand, that the power of deducing results from purely abstract premisses, without recourse to the aid of tangible models, should be more and more perfected, and on the other that purely abstract conceptions should be helped by objective and comprehensive models in cases where the mass of matter cannot be adequately dealt with directly.

Models in Mathematics and Physics.

In pure mathematics, especially geometry, models constructed of papier-mâché and plaster are chiefly employed to present to the senses the precise form of geometrical figures, surfaces and curves. Surfaces of the second order, represented by equations of the second degree between the rectangular co-ordinates of a point, are very simple to classify, and accordingly all their possible forms can easily be shown by a few models, which, however, become somewhat more intricate when lines of curvature, loxodromics and geodesic lines have to appear on their surfaces. On the other hand, the multiplicity of surfaces of the third order is enormous, and to convey their fundamental types it is necessary to employ numerous models of complicated, not to say hazardous, construction. In the case of more intricate surfaces it is sufficient to present those singularities which exhibit variation from the usual type of surface with synclastic or anticlastic curvatures, such as, for example, a sharp edge or point, or an intersection of the surface with itself; the elucidation of such singularities is of fundamental importance in modern mathematics.

In physical science, again, models that are of unchangeable form are largely employed. For example, the operation of the refraction of light in crystals can be pictured if we imagine a point in the centre of the crystal whence light is dispersed in all directions. The aggregate of the places at which the light arrives at any instant after it has started is called the wave-front. This surface consists of two cups or sheets fitting closely and exactly one inside the other. The two rays into which a single ray is broken are always determined by the points of contact of certain tangent-planes drawn to those sheets. With crystals possessing two axes these wave-surfaces display peculiar singularities in the above sense of the term, in that the inner sheet has four protuberances, while the outer has four funnel-like depressions, the lowest point of each depression meeting the highest point of each protuberance. At each of these funnels there is a tangent-plane that touches not in a single point, but in a circle bounding the depression, so that the corresponding ray of light is refracted, not into two rays, but into a whole cone of light—the so-called conical refraction theoretically predicted by Sir W. R. Hamilton and experimentally detected by Humphrey Lloyd. These conditions, which it is difficult to adequately express in language, are self-evident so soon as the wave-surface formed in plaster lies before our eyes. In thermodynamics, again, similar models serve, among other purposes, for the representation of the surfaces which exhibits the relation between the three thermodynamic variables of a body, *e.g.* between its temperature, pressure and volume. A glance at the model of such a thermodynamic surface enables the behaviour of a particular substance under the most varied conditions to be immediately realized. When the ordinate intersects the surface but once a single phase only of the body is conceivable, but where there is a multiple intersection various phases are possible, which may be liquid or gaseous. On the boundaries between these regions lie the critical phases, where transition occurs from one type of phase into the other. If for one of the elements a quantity which occurs in calorimetry be chosen—for example, entropy—information is also gained about the behaviour of the body when heat is taken in or abstracted.

After the stationary models hitherto considered, come the manifold forms of moving models, such as are used in geometry, to show the origin of geometrical figures from the motion of others—*e.g.* the origin of surfaces from the motion of lines. These include the thread models, in which threads are drawn tightly between movable bars, cords, wheels, rollers, &c. In mechanics and engineering an endless variety of working models are employed to convey to the eye the working either of machines as a whole, or of their component and subordinate parts. In theoretical mechanics models are often used to exhibit the physical laws of motion in interesting or special cases—*e.g.* the motion of a falling body or of a spinning-top, the movement of a pendulum on the rotating earth, the vortical motions of fluids, &c. Akin to these are the models which execute more or less exactly the hypothetical motions by which it is sought to explain various physical phenomena—as, for instance, the complicated wave-machines which present the motion of the particles in waves of sound (now ascertained with fair accuracy), or the more hypothetical motion of the atoms of the aether in waves of light.

Theories of Nature.

The varying importance which in recent times has been attached to models of this kind is intimately connected with the changes which have taken place in our conceptions of nature. The first method by which an attempt was made to solve the problem of the universe was entirely under the influence of Newton's laws. In analogy to his laws of universal gravitation, all bodies were conceived of as consisting of points of matter—atoms or molecules—to which was attributed a direct action at a distance. The circumstances of this action at a distance, however, were conceived as differing from those of the Newtonian law of attraction, in that they could explain the properties not only of solid elastic bodies, but also those of fluids, both liquids and gases. The phenomena of heat were explained by the motion of minute particles absolutely invisible to the eye, while to explain those of light it was assumed that an impalpable medium, called luminiferous aether, permeated the whole universe; to this were attributed the same properties as were possessed by solid bodies, and it was also supposed to consist of atoms, although of a much finer composition. To explain electric and magnetic phenomena the assumption was made of a third species of matter—electric fluids which were conceived of as being more of the nature of fluids, but still consisting of infinitesimal particles, also acting directly upon one another at a distance. This first phase of theoretical physics may be called the direct one, in that it took as its principal object the investigation of the internal structure of matter as it actually exists. It is also known as the mechanical theory of nature, in that it seeks to trace back all natural phenomena to motions of infinitesimal particles, *i.e.* to purely mechanical phenomena. In explaining magnetic and electrical phenomena it inevitably fell into somewhat artificial and improbable hypotheses, and this induced J. Clerk Maxwell, adopting the ideas of Michael Faraday, to propound a theory of electric and magnetic phenomena which was not only new in substance, but also essentially different in form. If the molecules and atoms of the old theory were not to be conceived of as exact mathematical points in the abstract sense, then their true nature and form must be regarded as absolutely unknown, and their groupings and motions, required by theory, looked upon as simply a process having more or less resemblance to the workings of nature, and representing more or less exactly certain aspects incidental to them. With this in mind, Maxwell propounded certain physical theories which were purely mechanical so far as they proceeded from a conception of purely mechanical processes. But he explicitly stated that he did not believe in the existence in nature of mechanical agents so constituted, and that he regarded them merely as means by which phenomena could be reproduced, bearing a certain similarity to those actually existing, and which also served to include larger groups of phenomena in a uniform manner and to determine the relations that held in their case. The question no longer being one of ascertaining the actual internal structure of matter, many mechanical analogies or dynamical illustrations became available, possessing different advantages; and as a matter of fact Maxwell at first employed special and intricate mechanical arrangements, though later these became more general and indefinite. This theory, which is called that of mechanical analogies, leads to the construction of numerous mechanical models. Maxwell himself and his followers devised many kinematic models, designed to afford a representation of the mechanical construction of the ether as a whole as well as of the separate mechanisms at work in it: these resemble the old wave-machines, so far as they represent the movements of a purely hypothetical mechanism. But while it was formerly believed that it was allowable to assume with a great show of probability the actual existence of such mechanisms in nature, yet nowadays philosophers postulate no more than a partial resemblance between the phenomena visible in such mechanisms and those which appear in nature. Here again it is perfectly clear that these models of wood, metal and cardboard are really a continuation and integration of our process of thought; for, according to the view in question, physical theory is merely a mental construction of mechanical models, the working of which we make plain to ourselves by the analogy of mechanisms we hold in our hands, and which have so much in common with natural phenomena as to help our comprehension of the latter.

Although Maxwell gave up the idea of making a precise investigation into the final structure of matter as it actually is, yet in Germany his work, under G. R. Kirchhoff's lead, was carried still further. Kirchhoff defined his own aim as being to describe, not to explain, the world of phenomena; but as he leaves the means of description open his theory differs little from Maxwell's, so soon as recourse is had to description by means of mechanical models and analogies. Now the resources of pure mathematics being particularly suited for the exact description of relations of quantity, Kirchhoff's school laid great stress on description by mathematical expressions and formulae, and the aim of physical theory came to be regarded as mainly the construction of formulae by which phenomena in the various branches of physics should be determined with the greatest approximation to the reality. This view of the nature of physical theory is known as mathematical phenomenology; it is a presentation of phenomena by analogies, though only by such as may be called mathematical.

Another phenomenology in the widest sense of the term, maintained especially by E. Mach, gives less prominence to mathematics, but considers the view that the phenomena of motion are essentially more fundamental than all the others to have been too hastily taken. It rather emphasizes the prime importance of description in the most general terms of the various spheres of phenomena, and holds that in each sphere its own fundamental law and the notions derived from this must be employed. Analogies and elucidations of one sphere by another —*e.g.* heat, electricity, &c.—by mechanical conceptions, this theory regards as mere ephemeral aids to perception, which are necessitated by historical development, but which in course of time either give place to others or entirely vanish from the domain of science.

All these theories are opposed by one called energetics (in the narrower sense), which looks upon the conception of energy, not that of matter, as the fundamental notion of all scientific investigation. It is in the main based on the similarities energy displays in its various spheres of action, but at the same time it takes its stand upon an interpretation or explanation of natural phenomena by analogies which, however, are not mechanical, but deal with the behaviour of energy in its various modes of manifestation.

Experimental Models.

A distinction must be observed between the models which have been described and those experimental models which present on a small scale a machine that is subsequently to be completed on a larger, so as to afford a trial of its capabilities. Here it must be noted that a mere alteration in dimensions is often sufficient to cause a material alteration in the action, since the various capabilities depend in various ways on the linear dimensions. Thus the weight varies as the cube of the linear dimensions, the surface of any single part and the phenomena that depend on such surfaces are proportionate to the square, while other effects—such as friction, expansion and conduction of heat, &c., vary according to other laws. Hence a flying-machine, which when made on a small scale is able to support its own weight, loses its power when its dimensions are increased. The theory, initiated by Sir Isaac Newton, of the dependence of various effects on the linear dimensions, is treated in the article Units, Dimensions of. Under simple conditions it may often be affirmed that in comparison with a large machine a small one has the same capacity, with reference to a standard of time which must be diminished in a certain ratio.

Of course experimental models are not only those in which purely mechanical forces are employed, but also include models of thermal, electro-magnetic and other engines—*e.g.* dynamos and telegraphic machines. The largest collection of such models is to be found in the museum of the Washington Patent Office. Sometimes, again, other than purely mechanical forces are at work in models for purposes of investigation and instruction. It often happens that a series of natural processes—such as motion in liquids, internal friction of gases, and the conduction of heat and electricity in metals—may be expressed by the same differential equations; and it is frequently possible to follow by means of measurements one of the processes in question—*e.g.* the conduction of electricity just mentioned. If then there be shown in a model a particular case of electrical conduction in which the same conditions at the boundary hold as in a problem of the internal friction of gases, we are able by measuring the electrical conduction in the model to determine at once the numerical data which obtain for the analogous case of internal friction, and which could only be ascertained otherwise by intricate calculations. Intricate calculations, moreover, can very often be dispensed with by the aid of mechanical devices, such as the ingenious calculating machines which perform additions and subtractions and very elaborate multiplications and divisions with surprising speed and accuracy, or apparatus for solving the higher equations, for determining the volume or area of geometrical figures, for carrying out integrations, and for developing a function in a Fourier's series by mechanical means. (L. Bo.)

MODELS, ARTISTS', the name given to persons who pose to artists as models for their work. The Greeks, who had the naked body constantly before them in the exercises of the gymnasium, had far less need of professional models than the moderns; but it is scarcely likely that they could have attained to the high level reached by their works without constant study from nature; and the story told of Zeuxis by Valerius Maximus, who had five of the most beautiful virgins of the city of Crotona offered him as models for his picture of Helen, proves their occasional use. The remark of Eupompus, quoted by Pliny, who advised Lysippus, "Let nature be your model, not an artist," directing his attention to the crowd instead of to his own work, also suggests a use of models which the many portrait statues of Greek and Roman times show to have been not unknown. In Egypt, too, although the priesthood had control of both sculpture and painting as used for the decoration of temples and palaces, and imposed a strict conventionalism, there are several statues of the early periods which are so lifelike in their treatment as to make it certain that they must have been worked from life. At the period of the Renaissance, painters generally made use of their relations and friends as models, of which many examples might be quoted from Venice, Florence, Rome and other places, and the stories of Titian and the duchess of Ferrara, and Botticelli and Simonetta Vespucci, go to show that ladies of exalted rank were sometimes not averse from having their charms immortalized by the painter's brush. But paid models were not unknown, as the story of the unfortunate contadino used by Sansovino as model for his statue of the little Bacchus will show. Artists' models as a special class appear when the establishment of schools for the study of the human figure created a regular demand, and since that time the remuneration offered has ensured a continual supply. The prices and the hours of work vary in different art centres. In England seven shillings is generally paid for a day of six hours, but models of exceptional beauty or talent frequently obtain more from successful artists or wealthy amateurs.

MODEL-YACHTING, the pastime of building and racing model-yachts. It has always been customary for ship-builders to make a miniature model of the vessel under construction; which is in every respect a copy of the original on a small scale; whether steam-ship or sailing-vessel (there is a fine collection in the Victoria and Albert Museum, London). Many of these models are of exquisite workmanship, every rope, pulley or portion of the engine being faithfully reproduced. In the case of sailing yachts these models were often pitted against each other on small bodies of water, and hence arose the modern pastime. It was soon seen that elaborate fittings and complicated rigging were a detriment to rapid handling, and that, on account of the comparatively stronger winds in which models were sailed, they needed a greater draught. For these reasons modern model yachts, which usually have fin-keels, are of about 15% or 20% deeper draught than full-sized vessels, while rigging and fittings have been reduced to absolute simplicity. This applies to models built for racing and not to elaborate copies of steamers and ships, made only for show or for "toy cruising."

Model-yacht clubs have existed for many years in Great Britain, Ireland and the United States, most of them holding a number of regattas during each season. The rules do not generally require the owner or skipper of a model to build his own craft, but among model-yachtsmen the designing and the construction of the boats constitute as important and interesting a part of the sport as the actual sailing. Models are constructed of some light, seasoned wood—such as pine (preferably white), white cedar or mahogany—free from knots. The hull may either be hollowed out of a solid block of wood, or cut from layers of planks in the so-called "bread-and-butter" style, or planked over a frame of keel and cross-sections. The first two methods are used in constructing "dug-out" models. Hollowing out from the solid block entails a great deal of labour and has therefore fallen into disfavour. In the "bread-and-butter" style a number of planks, which have been shaped to the horizontal sections of the model and from which the middle has been sawn out, are glued together and then cut down to the exact lines of the design, templates being used to test the precision of the curves. In the planked, or "built-up" model, which is generally chosen by more expert builders, the planks are tacked to the frame, as in the construction of large vessels. Models now are generally exaggerated cutters, so far as their underbodies are concerned, or, more often, are fitted with fin-keels weighted with lead, after the manner of full-sized yachts. They may have any rig, but schooner and sloop rigs are most common, the latter being the favourite for racing on account of its simplicity. Two kinds of steering-gear are used, the weighted swinging rudder and the "main-sheet balance gear," the object of both being to keep the model on a true course, either before or against the wind. Models are often sailed without rudders, but though a perfectly built boat will sail readily against the wind without steering-gear, it is almost impossible to keep it on its course before the wind without some contrivance to check divergence. This is accomplished by the weighted rudder, which falls over when the vessel heels and tends to counteract the force of the breeze. There are two varieties of the weighted rudder, in the first of which the weight, usually lead, is fixed to the edge of the rudder, while in the second the weight, usually a ball of lead, is made to run on the tiller above the deck, so that it can be placed further forward or aft, according to the force needed to overcome the influence of the wind. While the weighted rudder is almost universal in the British Isles, the chief model-yachtsmen in America use the "main-sheet balance gear," in which the boom is connected with the tiller in such a manner that, when it swings out with a pressure of wind, the rudder is automatically pulled round sufficiently to keep the yacht in its course. This apparatus is particularly efficient in sailing before the wind.

Model-yacht regattas are very different from the toy-boat matches indulged in by children from one side of a pond to the other. They take place upon sufficiently large bodies of water to allow a course at least a quarter of a mile in length, which is generally sailed twice or three times over to windward and backward. Triangular courses are also sailed. Racing rules correspond generally to those controlling regattas of large boats, and there is full scope to exhibit all the proofs of good seamanship. The yachts are followed in light skiffs, and may not be touched more than a certain number of times during a race, on penalty of a handicap. Racing measurements differ in the various clubs, but all are based upon length and sail-area. In Great Britain the regular Yacht Racing Association rule has been generally adopted, and handicaps deducted from it. In America models are divided into a single schooner with a maximum load water-line of 63 in., and three classes of sloops, the first class including yachts with water-lines between 48 and 53 in., the second class those between 42 and 48 in. and the third and smallest class those between 35 and 42 in. A yacht with a shorter water-line than 35 in. must race in the third class. It has been found that yachts of smaller dimensions possess too little resistance to the wind.

See *Model Sailing Yachts*, in Marshall's Practical Manuals series, 1905; and *How to Build a Model Yacht*, by Herbert Fisher (New York, 1902).

MODENA (ancient *Mutina*), one of the principal cities of Emilia, Italy, the chief town of the province of Modena and the seat of an archbishop, 31 m. E.S.E. of Parma by rail. Pop. (1906), 26,847 (town); 66,762 (commune). It is situated in a damp, low plain in the open country in the south side of the valley of the Po, between the Secchia to the west and the Panaro to the east. Some of its main streets (as their names indicate) follow the lines of canals, which still (though now covered) traverse the city in various directions. The observatory stands 135 ft. above the level of the sea. Dismantled since 1816, and now largely converted into promenades, the fortifications give the city an irregular pentagonal contour, modified at the north-west corner by the addition of a citadel also pentagonal Within this circuit there are various open areas—the spacious Ippodromo in front of the citadel, the public gardens in the north-east of the city, the Piazza Grande in front of the cathedral, and the Piazza Reale to the south of the palace. The Via Aemilia passes obliquely right through the heart of the city, from the Bologna Gate in the east to that of Sant' Agostino in the west.

Begun by the Countess Matilda of Tuscany in 1099, after the designs of Lanfranc, and consecrated in 1184, the Romanesque cathedral (S Geminiano) is a low but handsome building, with a lofty crypt, under the choir (characteristic of the Tuscan Romanesque architecture), three eastern apses, and a façade still preserving some curious sculptures of the 12th century. The interior was restored in 1897. The graceful bell-tower, erected in 1224–1319, named La Ghirlandina from the bronze garland surrounding the weathercock, is 335 ft. high; in the basement may be seen the wooden bucket captured by the Modenese from the Bolognese in the affray at Zappolino (1325), and rendered famous by Tassoni's *Secchia Rapita*. Of the other churches in Modena, the church of S Giovanni Decollato contains a *Pieta* in painted terra-cotta by Guido Mazzoni (1450–1518). The so-called Pantheon Estense (the church of S. Agostino, containing works of sculpture in honour of the house of Este) is a baroque building by Bibbiena; it also contains the tombs of Sigonio and Muratori. San Pietro and San Francesco have terra-cottas by Begarelli (1498–1565). The old ducal palace, begun by Duke Francis I. in 1635 from the designs of Avanzini, and finished by Francis Ferdinand V., is an extensive building with a fine courtyard, and now contains the military school and the observatory. The Albergo d' Arti, built by Duke Francis III., accommodates the civic collections, comprising the Museo Lapidario (Roman inscriptions, &c.); the valuable archives, the Biblioteca Estense, with 90,000 volumes and 3000 MSS.; the Museo Civico, with large and good palaeo-ethnological and archaeological collections; a fine collection of textile fabrics, and the picture gallery, a good representative collection presented to the city by Francis V. and since augmented by the addition of the collection of the Marchese Campori. Many of the best pictures in the ducal collection were sold in the 18th century and found their way to Dresden. The town hall is a noteworthy building, with arcades dating from 1194, but in part rebuilt in 1826. The university of Modena, originally founded in 1683 by Francis II., is mainly a medical and legal school, but has also a faculty of physical and mathematical science. The old academy of the *Dissonanti*, dating from 1684, was restored in 1814, and now forms the flourishing Royal Academy of Science and Art. In industrial enterprise silk and linen goods and iron wares are almost the only products of any note. Commerce is chiefly agricultural and is stimulated by a good position in the railway system, and by a canal which opens a water-way by the Panaro and the Po to the Adriatic. Modena is the point at which the railway to Mantua and Verona diverges from that between Milan and Bologna, and has several steam tramways to neighbouring places. It is also the starting-point of a once important road over the Apennines to Pistoia by the Abetone Pass.

Modena is the ancient *Mutina* in the territory of the Boii, which came into the possession of the Romans probably in the war of 215–212 B.C. In 183 B.C. Mutina became the seat of a Roman colony. The Roman town lay immediately to the south-east of the modern; its north-western wall is marked by the modern Corso Umberto I. (formerly Canal Grande) It appears to have been a place of importance under the empire, but none of its buildings is now to be seen. The Roman level, indeed, is some 15 to 20 ft. below the modern town. Its vineyards and potteries are mentioned by Pliny, the latter doing a considerable export trade. Its territory was coterminous with that of Bononia and Regium, as its diocese is now, and to the south it seems to have extended to the summit of the Apennines. During the civil wars Marcus Brutus, the lieutenant of Lepidus, held out within its walls against Pompeius in 78 B.C., and in 44 B.C. the place was successfully defended by D. Brutus against Mark Antony for four months. The 4th century found Mutina in a state of decay; the ravages of Attila and the troubles of the Lombard period left it a ruined city in a wasted land. In the 7th century, perhaps owing to a terrible inundation,[1] its exiles founded, at a distance of 4 m. to the north-west, a new city, Città Geminiana (still represented by the village of Cittanova); but about the close of the 9th century Modena was restored and refortified by its bishop, Ludovicus. When it began to build its cathedral (A.D. 1099) the city was part of the possessions of the Countess Matilda of Tuscany; but when, in 1184, the edifice was consecrated by Lucius III., it was a free community. In the wars between Frederick II. and Gregory IX. it sided with the emperor, though ultimately the papal party was strong enough to introduce confusion into its policy. In 1288 Obizzo d'Este was recognized as lord of the city; after the death of his successor, Azzo VIII. (1308), it resumed its communal independence; but by 1336 the Este family was again in power. Constituted a duchy in 1452 in favour of Borso d'Este, and enlarged and strengthened by Hercules II., it became the ducal residence on the incorporation of Ferrara with the States of the Church (1598). Francis I. (1629–1658) erected the citadel and commenced the palace, which was largely embellished by Francis II. Rinaldo (*ob.* 1737) was twice driven from his city by French invasion. To Francis III. (1698–1780) the city was indebted for many of its public buildings. Hercules III. (1727–1803) saw his states transformed by the French into the Cispadine Republic, and, having refused the principality of Breisgau and Ortenau, offered him in compensation by the treaty of Campo Formio, died an exile at Treviso. His only daughter, Maria Beatrice, married Ferdinand of Austria (son of Maria Theresa), and in 1814 their eldest son, Francis, received back the *Stati Estensi*. His rule was subservient to Austria, reactionary and despotic. On the outbreak of the French Revolution of 1830, Francis IV. seemed for a time disposed to encourage the corresponding movement in Modena; but no sooner had the Austrian army put an end to the insurrection in Central Italy than he returned to his previous policy. Francis Ferdinand V., who succeeded in 1846, followed in the main his father's example. Obliged to leave the city in 1848, he was restored by the Austrians in 1849; ten years later, on the 20th of August 1859, the representatives of Modena declared their territory part of the kingdom of Italy, and their decision was confirmed by the plebiscite of 1860.

See Vedriani, *Storia di Modena* (1666); Tiraboschi, *Mem. storiche modenesi* (1793); Scharfenberg, *Gesch. des Herzogth. Modena* (1859); Oreste Raggi, *Modena descritta* (1860); Baraldi, *Storia di Modena*; Valdrighi, *Diz. Storico, &c., delle contrade di Modena* (1798–1880); Crespellani, *Guida di Modena* (1879); Cavedoni, *Dichiarazione degli antici marmi Modenesi* (1828).

MODERATOR (from Lat. *moderare*, to impose a *modus*, limit), a judge or umpire, one who acts the part of mediator, and so a term used of the person chosen to be president of a meeting (as in America, of a town meeting). In academic use, the word was formerly applied to the public officer who presided over the exercises, &c., prescribed for candidates for degrees in the university schools; it is now used at Cambridge of one or two officers who are appointed each year to preside over the examination for the mathematical tripos, at Oxford of an examiner in the first public examination, known as "moderations," and at Dublin of a candidate for honours in the examination for degree of Bachelor of Arts. In the Presbyterian churches the name is applied to the minister elected to preside over ecclesiastical meetings or assemblies, as the synod, presbytery or general assembly (see PRESBYTERIANISM). The name was historically given to a party of people who joined together to oppose the "Regulators," another party who professed to administer justice in the Carolinas (1767–1771). Technically, the word is also used of a particular form of lamp, in which the flow of oil from the reservoir to the burner is regulated by a mechanical arrangement to which the name is applied.

MODERATUS OF GADES, a Greek philosopher of the Neo-Pythagorean school, contemporary with Apollonius of Tyana. He wrote a great work on the doctrines of the Pythagoreans, and tried to show that the successors of Pythagoras had made no additions to the views of their founder, but had merely borrowed and altered the phraseology. He has been given a fictitious importance by recent commentators, who have regarded him as the forerunner of the Alexandrian School of philosophy. Zeller has shown that the authority on which this view is based is entirely unsound. Moderatus is thus left as an unimportant though interesting representative of a type of thought which had almost disappeared since the 5th century B.C.

Stobaeus, *Eclogae*, p. 3, preserves a fragment of his writings.

MODESTINUS, HERENNIUS, a celebrated Roman jurist, who flourished about 250 B.C. He appears to have been a native of one of the Greek-speaking provinces, probably Dalmatia, and was a pupil of Ulpian. In Valentinian's *Law of Citations* he is classed with Papinian, Paulus, Gaius and Ulpian. He is mentioned in a rescript of Gordian in the year 240 B.C. in connexion with a *responsum* which he gave to the party to whom the rescript was addressed. No fewer than 345 passages in the *Digest* are taken from his writings.

MODICA, a town of Sicily, in the province of Syracuse, 57 m. W.S.W. of Syracuse by rail and 33 m. direct. Pop. (1901), 48,962. It lies on a hill between two valleys; the hill, crowned by the church of S. Giorgio, reconstructed in the 17th century, was the site of the Sicel town of Motyca, while the modern part of the town extends along the river Mauro, an inundation of which did much damage in September 1902. Remains of megalithic buildings, apparently, however, houses of the Byzantine period, are described in *Notizie degli Scavi*, 1896, 242 seq. Six miles to the south-east is the valley known as the Cava d'Ispica, with hundreds of grottoes cut in its rocky sides; of these only a few are Sicel tombs, the majority being catacombs or open tombs of the early Christian and Byzantine periods, or even cave-dwellings of the latter age.

See P. Orsi in *Notizie degli Scavi* (1905), 431.

MODILLION (a French word, probably from Lat. *modulus*, a measure of proportion), a term in architecture for the enriched block or horizontal bracket generally found under the cornice and above the bedmould of the Corinthian entablature. It is probably so called because of its arrangement in regulated distances.

MODJESKA, HELENA (1844–1909), Polish actress, was born at Cracow on the 12th of October 1844. Her father, Michael Opido, was a musician, and her tastes soon declared themselves strongly in favour of a dramatic career; but it was not until after her marriage in 1861 that she first attempted to act, and then it was with a company of strolling players. Her husband (whose name, Modrzejewski, she simplified for stage purposes) died in 1865. In 1868 she married Count Bozenta Chlapowski, a Polish politician and critic, and almost immediately afterwards received an invitation to act at Warsaw. There she remained for seven or eight years, and won a high position in her art. Her chief tragic rôles were Ophelia, Juliet, Desdemona, Queen Anne in *Richard III.*, Louisa Miller, Maria Stuart, Schiller's Princess Eboli, Marion Delorme, Victor Hugo's Tisbé and Slowacki's Mazeppa. In comedy her favourite rôles were Beatrice in *Much Ado About Nothing*, and Donna Diana in the Polish translation of an old Spanish play of that name. Madame Modjeska was also the Polish interpretress of the most prominent plays of Legouvé, Dumas, father and son, Augier, Alfred de Musset, Octave Feuillet and Sardou. In 1876 she went with her husband to California, where they settled on a ranch. This new career, however, proved a failure, and Madame Modjeska returned to the stage. She appeared in San Francisco in 1877, in an English version of *Adrienne Lecouvreur*, and, in spite of her imperfect command of the language, achieved a remarkable success. She continued to act principally in America, but was also seen from time to time in London and elsewhere in the United Kingdom, her repertory including several Shakespearian rôles and a variety of emotional parts in modern drama. She died on the 9th of April 1909 at her home near Los Angeles, California.

---

[1] Some authorities (of whom Tiraboschi was the first) attribute its desertion entirely to a succession of inundations, denying that it was even among the cities destroyed by Attila.

See Mabel Collins, *The Story of Helena Modjeska* (London, 1883), and the (autobiographical) *Memories and Impressions* (New York, 1910).

MÖDLING, an old town of Austria, in Lower Austria, 10 m. S. of Vienna by rail. Pop. (1900), 15,304. It is situated at the entrance of the Brühl valley and is a popular summer resort, possessing iron and sulphur baths. It possesses a Gothic church, with a crypt dating from the 15th century, and a still older Romanesque burial chapel. It has a considerable iron and metal industry, and manufactures of shoes, varnish, &c.

MODOC (*i.e.* "southerners"), a tribe of North American Indians of the Lutuamian stock, who formerly lived around Lower Klamath Lake, south-western Oregon. They were always an aggressive people, and constantly at war with their neighbours. They are known mainly from their stubborn resistance to the United States government in 1872 and 1873. This is called the Modoc War, and was caused by an attempt to place them on a reservation. After some preliminary fighting the Modocs retreated to the "Lava Beds," a basaltic region, seamed and crevassed, and rich in caves. Here they made a stand for several months. During the war two members of a peace commission were treacherously massacred by them while under a flag of truce. On their final submission the leaders were hanged and part of the tribe was removed to Indian Territory (now Oklahoma), and the others were sent back to a reservation on the Klamath.

MODULE (Lat. *modulus*, a measure), in architecture, the semi-diameter of the column at its base; the term was first set forth by Vitruvius (iv. 3), and was generally employed by the architects of the Italian revival to determine the relative proportions of the various parts of a columnar ordinance. The module was divided by the revivalists into thirty parts, called minutes, allowing of much greater accuracy than was thought necessary by Vitruvius, whose subdivision was usually six parts. The tendency now is to adopt the whole diameter instead of the semi-diameter when determining the height of the column or entablature or any of their subdivisions. The term module is also applied in hydraulics (*q.v.*) to a contrivance for regulating the supply of water from an irrigation channel.

MOERIS, AELIUS, Greek grammarian, surnamed *Atticista* ("the Atticist"), probably flourished in the 2nd century A.D. He was the author of an extant (more or less alphabetical) list of Attic forms and expressions (Ἀττικαὶ λέξεις), accompanied by the Hellenistic parallels of his own time, the differences of gender, accent and meaning being clearly and succinctly pointed out.

Editions by J. Hudson (1711); J. Pierson (1759); A. Koch (1830); I. Bekker (1833); with Harpocration.

MOERIS, LAKE OF, the lake which formerly filled the deep depression of the Fayum to the Nile level, now shrunken and sunk more than 200 ft. to the shallow Birket el Kerūn. In remote prehistoric times the Fayum depression was probably dry, but with the gradual rise of the river bed the high Nile reached a level at which it could enter through the natural or artificial channel now known as the Bahr Yusuf. The borders of the lake were occupied by a neolithic people, and the town of Crocodilopolis grew up very early on the eastern slope south of the channel, where the higher ground formed a ridge in the lake. The rise continuing (at the rate of about 4 in. to the century) the waters threatened to flood the town; consequently under the XIIth Dynasty great embankments were made to save the settled land from encroachment. The line of the embankment is still traceable in places and marked by monuments of the XIIth Dynasty kings, an obelisk of Senwosri I. at Ebgig, and colossi of Amenemhê III. at Biahmu. The latter ornamented the quay of the port of Crocodilopolis, and projected into the lake on high bases. As the Nile fell the broad expanse of the lake lowered, and the water pouring back through the channel was of value for summer irrigation; the inflow and outflow were regulated by sluices, and the capture of fish here and in the lake was enormous. The channel which was of such importance was called the "Great Channel," Mewêr, in Greek Moeris. The native name of the lake was Shei, "the lake," later Piôm, "the sea" (whence Fayum); Teshei, "the land of the lake," was the early name of the region. At its capital Crocodilopolis and elsewhere the crocodile god Sobk (Suchus) was worshipped. Senwosri II. of the XIIth Dynasty built his pyramid at Illahun at the outer end of the channel, Amenemhê III. built his near the inner end at Hawara, and the vast labyrinth attached to it was probably his funerary temple. This king was afterwards worshipped in more than one locality about the lake under the name Marres (his praenomen Nemarē) or Peremarres, *i.e.* Pharaoh Marres. The mud poured in at high Nile made rich deposits on the eastern slope; in the reign of Philadelphus large reclamations of land were made, veterans from the Syrian War were settled in the "Lake" (Λίμνη), and the latter quickly became a populous and very fertile province. Strabo's account of the Lake of Moeris must be copied from earlier writers, for in his day the outflow had been stopped probably for two centuries, and the old bed of the lake was dotted with flourishing villages to a great depth below the level of the Nile. Large numbers of papyri of the Ptolemaic and Roman periods have been found in and about the Fayum, which continued to flourish through the first two centuries of the Roman rule.

See W. M. F. Petrie, *Hawara Biahmu and Arsinoe* (London, 1889); R. H. Brown, *The Fayûm and Lake Moeris* (London, 1892); B. P. Grenfell, A. S. Hunt and D. G. Hogarth, *Fayum Towns and their Papyri* (London, 1900); H. J. C. Beadnell, *The Topography and Geology of the Fayum Province of Egypt* (Cairo, 1905). (F. Ll. G.)

MOESIA (Gr. Μυσία and Μυσία ἡ ἐν Εὐρώπῃ, to distinguish it from Mysia in Asia), in ancient geography, a district inhabited by a Thracian people, bounded on the S. by the mountain ranges of Haemus and Scardus (Scordus, Scodrus), on the W. by the Drinus, on the N. by the Danube and on the E. by the Euxine. It thus corresponded in the main to the modern Servia and Bulgaria. In 75 B.C., C. Scribonius Curio, proconsul of Macedonia, penetrated as far as the Danube, and gained a victory over the inhabitants, who were finally subdued by M. Licinius Crassus, grandson of the triumvir and also proconsul of Macedonia, during the reign of Augustus *c.* 29 B.C. (see Mommsen, *Provinces of the Roman Empire*, Eng. trans., i. 12–14). The country, however, was not organized as a province until the last years of the reign; in A.D. 6 mention is made of its governor, Caecina Severus (Dio Cassius lv. 29). The statement of Appian (*Illyrica*, 30) that it did not become a Roman province until the time of Tiberius, is therefore incorrect. Originally one province, under an imperial consular legate (who probably also had control of Achaea and Macedonia), it was divided by Domitian into Upper (*superior*) and Lower (*inferior*, also called *Ripa Thracia*) Moesia, the western and eastern portions respectively, divided from each other by the river Cebrus (Ciabrus; mod. Cibritza or Zibru). Some, however, place the boundary further west. Each was governed by an imperial consular legate and a procurator. As a frontier province, Moesia was strengthened by stations and fortresses erected along the southern bank of the Danube, and a wall was built from Axiopolis to Tomi as a protection against Scythian and Sarmatian inroads. After the abandonment of Dacia (*q.v.*) to the barbarians by Aurelian (270–275) and the transference of its inhabitants to the south of the Danube, the central portion of Moesia took the name of Dacia Aureliani (again divided into Dacia *ripensis* and *interior*). The district called Dardania (in Upper Moesia), inhabited by the Illyrian Dardani, was formed into a special province by Diocletian with capital Naissus (Nissa or Nish), the birthplace of Constantine the Great. The Goths, who had already invaded Moesia in 250, hard pressed by the Huns, again crossed the Danube during the reign of Valens (376), and with his permission settled in

Moesia. But quarrels soon took place, and the Goths under Fritigern defeated Valens in a great battle near Adrianople (378). These Goths are known as Moeso-Goths, for whom Ulfilas made the Gothic translation of the Bible. In the 7th century Slavs and Bulgarians entered the country and founded the modern kingdoms of Servia and Bulgaria. The chief towns of Upper Moesia were: Singidunum (Belgrade), Viminacium (sometimes called municipium Aelium; Kostolatz), Bononia (Widdin), Ratiaria (Artcher): of Lower Moesia; Oescus (colonia Ulpia, Gigen), Novae (near Sistova, the chief seat of Theodoric), Nicopolis ad Istrum (Nikup), really on the Iatrus or Yantra, Odessus (Varna), Tomi (Kustendje), to which the poet Ovid was banished. The last two were Greek towns, which, with Istros, Mesambria and Apollonia, formed a pentapolis.

F.)

MOFAḌḌALĪYĀT, strictly MUFAḌḌALĪYĀT, an anthology of ancient Arabic poems, which derives its name from al-Mufaḍḍal, son of Muḥammad, son of Ya'lā, a member of the tribe of Ḍabba, who compiled it some time between A.D. 762 and 784 in the latter of which years he died. Al-Mufaḍḍal was a contemporary of Ḥammād ar-Rāwiya and Khalaf al-Aḥmar, the famous collectors of ancient Arab poetry and tradition, and was somewhat the junior of Abū 'Amr ibn al-'Alā, the first scholar who systematically set himself to preserve the poetic literature of the Arabs. He died about fifty years before Abū 'Ubaida and al-Aṣma'ī, to whose labours posterity is largely indebted for the arrangement, elucidation and criticism of ancient Arabian verse; and his anthology was put together between fifty and sixty years before the compilation by Abū Tammām of the *Ḥamāsa* (*q.v.*).

Al-Mufaḍḍal was a careful and trustworthy collector both of texts and traditions, and is praised by all authorities on Arabian history and literature as in this respect greatly the superior of Ḥammād and Khalaf, who are accused (especially the latter) of unscrupulous fabrication of poems in the style of the ancients. He was a native of Kūfa, the northernmost of the two great military colonies founded in 638 by the caliph 'Omar for the control of the wide Mesopotamian plain. In Kūfa and Baṣra were gathered representatives of all the Arabian tribes who formed the fighting force of the Islamic Empire, and from these al-Mufaḍḍal was able to collect and record the compositions of the poets who had celebrated the fortunes and exploits of their forefathers. He, no doubt, like al-Aṣma'ī and Abū 'Ubaida, also himself visited the areas occupied by the tribes for their camping grounds in the neighbouring desert; and adjacent to Kūfa was al-Ḥīra, the ancient capital of the Lakhmid kings, whose court was the most celebrated centre in pre-Islamic Arabia, where, in the century before the preaching of the Prophet, poets from the whole of the northern half of the peninsula were wont to assemble. There is indeed a tradition that a written collection (*dīwān*) existed in the family of an-Nu'mān, the last Lakhmid king, containing a number of poems by the *Fuḥūl*, or most eminent poets of the pagan time, and especially by those who had praised the princes of the house, and that this collection passed into the possession of the Omayyad caliphs of the house of Marwān; to this, if the tradition is to be believed, al-Mufaḍḍal probably had access.

The date of al-Mufaḍḍal's birth is unknown; but he lived for many years under the caliphs of the Omayyad line until their overthrow by the 'Abbasids in 749. In 762 he took part in the rising led by Ibrāhīm ibn 'Abdallāh ibn al-Ḥasan, the 'Alid, called "The Pure Soul," against the caliph al-Manṣūr, and after the defeat and death of Ibrāhīm was cast into prison. Al-Manṣūr, however, pardoned him on the intercession of his fellow-tribesman Musayyab ibn Zuhair of Ḍabba, and appointed him the instructor in literature of his son, afterwards the caliph al-Mahdī. It was for this prince that, at al-Manṣūr's instigation, al-Mufaḍḍal compiled the *Mufaḍḍalīyāt*.

The collection, in its present form, contains 126 pieces of verse, long and short; that is the number included in the recension of al-Anbārī, who had the text from Abū 'Ikrima of Ḍabba, who read it with Ibn al-A'rābī, the stepson and inheritor of the tradition of al-Mufaḍḍal. We know from the *Fihrist* of Muḥammad an-Nadīm (A.D. 988) that in his time 128 pieces were counted in the book; and this number agrees with that contained in the Vienna MS., which gives an additional poem, besides those annotated by al-Anbārī, to al-Muraqqish the Elder, and adds at the end a poem by al-Ḥārith ibn Ḥilliza. The *Fihrist* states (p. 68) that some scholars included more and others fewer poems, while the order of the poems in the several recensions differed; but the correct text, the author says, is that handed down through Ibn al-A'rābī. It is noticeable that this traditional text, and the accompanying scholia, as represented by al-Anbārī's recension, are wholly due to the scholars of Kūfa, to which place al-Mufaḍḍal himself belonged. The rival school of Baṣra, on the other hand, has given currency to a story that the original collection made by al-Mufaḍḍal included a much smaller number of poems. The Berlin MS. of al-Marzūqī's commentary states that the number was thirty, but a better reading of the passage, found elsewhere,[1] mentions eighty; and that al-Asma'ī and his school added to this nucleus poems which increased the number to a hundred and twenty. It is curious that this tradition is ascribed by al-Marzūqī and his teacher Abū 'Alī al-Fārisī to Abū 'Ikrima of Ḍabba, who is represented by al-Anbārī as the transmitter of the correct text from Ibn al-A'rābī. There is no mention of it in al-Anbārī's work, and it is in itself somewhat improbable, as in al-Aṣma'ī's time the schools of Kūfa and Baṣra were in sharp opposition one to the other, and Ibn al-A'rābī in particular was in the habit of censuring al-Aṣma'ī's interpretations of the ancient poems. It is scarcely likely that he would have accepted his rival's additions to the work of his step-father, and have handed them on to Abū 'Ikrima with his annotations.

The collection is one of the highest importance as a record of the thought and poetic art of Arabia during the time immediately preceding the appearance of the Prophet. Not more than five or six of the 126 poems appear to have been composed by poets who had been born in Islam. The great majority of the authors belonged to the days of "the Ignorance," and though a certain number (*e.g.* Mutammim ibn Nuwaira, Rabī'a ibn Maqrūm, 'Abda ibn aṭ-Ṭabīb and Abū Dhu'aib), born in paganism, accepted Islām, their work bears few marks of the new faith. The ancient virtues—hospitality to the guest and the poor, profuse expenditure of wealth, valour in battle, faithfulness to the cause of the tribe—are the themes of praise; wine and the game of *maisir*, forbidden by Islām are celebrated by poets who professed themselves converts and if there is no mention of the old idolatry, there is also little spirituality in the outlook on life. The 126 pieces are distributed between 68 poets, and the work represents a gathering from the compositions of those who were called *al-Muqillūn*, "authors of whom little has survived," in contrast to the famous poets whose works had been collected into *dīwāns* At the same time many of them are extremely celebrated, and among the pieces selected by al-Mufaḍḍal several reach a very high level of excellence. Such are the two long poems of 'Alqama ibn 'Abada (Nos. 119 and 120), the three odes by Mutammim ibn Nuwaira (Nos. 9, 67, 68), the splendid poem of Salāma ibn Jandal (No. 22), the beautiful *nasīb* of ash-Shanfarā (No. 20) and the death-song of 'Abd-Yaghūth (No. 30). One of the mos admirable and famous is the last of the series (No. 126), the long elegy by Abū Dhu'aib of Hudhail on the death of his sons almost every verse of this poem is cited in illustration of some phrase or meaning of a word in the national lexicons. Only one of the poets of the *Mu'allaqāt* (see MO'ALLAKĀT), al-Ḥārith, son of Ḥilliza, is represented in the collection. Of others (such as Bishr ibn Abī Khāzim, al-Ḥādira, 'Āmir ibn aṭ-Ṭufail, 'Alqamah ibn 'Abadah, al-Muthaqqib, Ta'abbaṭa Sharrā and Abū Dhu'aib) *dīwāns* or bodies of collected poems exist, but it is doubtfu how far these had been brought together when al-Mufaḍḍal made his compilation. An interesting feature of the work is the treatment in it of the two poets of Bakr ibn Wā'il, uncle and nephew, called al-Muraqqish, who are perhaps the most ancient in the collection. The elder Muraqqish was the great-uncle of Ṭarafa of Bakr, the author of the *Muʽallaqa*, and took part in the long warfare between the sister tribes of Bakr and Taghlib, called the war of Basūs, which began about the end of the 5th century A.D. Al-Mufaḍḍal has included ten pieces (Nos. 45–54) by him in the collection, which are chiefly interesting from an antiquarian point of view. One, in particular (No. 54), presents a very archaic appearance. It is probable that the compiler set down all he could gather of this ancient author, and that his interest in him was chiefly due to his antiquity. Of the younger Muraqqish, uncle of Ṭarafa, there are five pieces (Nos. 55–59). The only other authors of whom more than three poems are cited are Bishr ibn Abī Khāzim of Asad (Nos. 96–99) and Rabīʽa ibn Maqrūm of Ḍabba (Nos. 38, 39, 43 and 113).

---

[1] In the *dhail* or supplement to the *Amālī* of al-Qālī. (Edn Cairo 1324 H., p. 131).

The *Mufaḍḍalīyāt* differs from the *Ḥamāsa* in being a collection of complete odes (*qaṣīdas*), while the latter is an anthology of brilliant passages specially selected for their interest or effectiveness, all that is prosaic or less striking being pruned away. It is of course not the case that all the poems of al-Mufaḍḍal's collection are complete. Many are mere fragments, and even in the longest there are often *lacunae*; but the compiler evidently set down all that he could collect of a poem from the memory of the *rāwīs*, and did not, like Abū Tammām, choose only the best portions. We are thus presented with a view of the literature of the age which is much more characteristic and comprehensive than that given by the brilliant poet to whom we owe the *Ḥamāsa*, and enables us to form a better judgment on the general level of poetic achievement.

The *Mufaḍḍalīyāt* is not well represented by MSS. in the libraries of the West. There is an imperfect copy of the recension of al-Marzūqī (died 1030), with his commentary, in the Berlin collection. A very ancient fragment (dated 1080) of al-Anbārī's recension, containing five poems in whole or part, is in the Royal Library at Leipzig. In the British Museum there is a copy made about a century ago for C. J. Rich at Bagdad of a MS. with brief glosses; and at Vienna there is a modern copy of a MS. of which the original is at Constantinople, the glosses in which are taken from al-Anbārī, though the author had access also to al-Marzūqī. In the mosque libraries at Constantinople there are at least five MSS.; and at Cairo there is a modern copy of one of these, containing the whole of al-Anbārī's commentary. In America there are at Yale University a modern copy of the same recension, taken from the same original as the Cairo copy, and a MS. of Persian origin, dated 1657, presenting a text identical with the Vienna codex. Quite recently a very interesting MS., probably of the 6th century of the Hegira, but not dated, has come to light. It purports to be the second part of a combination of two anthologies, the *Mufaḍḍalīyāt* of al-Mufaḍḍal and the *Aṣmaʽīyāt* of al-Aṣmaʽī, but contains many more poems than are in either of these collections as found elsewhere. The commentary appears to be eclectic, drawn partly (perhaps chiefly) from Ibn as-Sikkīt (died 858), and partly from Abū-Jaʽfar Aḥmad ibn ʽUbaid ibn Nāṣih, one of al-Anbārī's sources and a pupil of Ibn al-Aʽrābī; and the compilation seems to be older in date than al-Anbāri, since its glosses are often quoted by him without any name being mentioned. This MS. (which is the property of Mr F. Krenkow of Leicester) appears to represent one of the recensions mentioned by Muḥammad an-Nadīm in the *Fihrist* (p. 68), to which reference has been made above.

In 1885 Professor Heinrich Thorbecke began an edition of the text based on the Berlin codex, but only the first fasciculus, containing forty-two poems, had appeared when his work was cut short by death. In 1891 the first volume of an edition of the text, with a short commentary taken from al-Anbārī, was printed at Constantinople. In 1906 an edition of the whole text, with short glosses taken from al-Anbārī's commentary, was published at Cairo by Abū Bakr b. ʽOmar Dāghistānī al-Madanī; this follows generally the Cairo codex above mentioned, but has profited by the scholarship of Professor Thorbecke's edition of the first half of the work. A complete edition of al-Anbārī's text and commentary, with a translation of the poems, undertaken by Sir C. J. Lyall (see *J. R. A. S.*, April 1904) was in the press in 1910. (C. J. L.)

MOFETTA (Ital. from Lat. *mephitis*, a pestilential exhalation), a name applied to a volcanic discharge consisting chiefly of carbon dioxide, often associated with other vapours, representing the final phase of volcanic activity. The word is used frequently in the plural as mofette, or, following the French, *mofettes*. The volcanic vents yielding the emanations are themselves called mofette. They are not uncommon in Auvergne and in the Eifel, notably on the shore of the Laacher See; whilst other examples are furnished by the Grotta del Cane, near Puzzuoli, the Valley of Death in Java, and the Death Gulch in the Yellowstone Park.

MOFFAT, ROBERT (1795–1883), Scottish Congregationalist missionary to Africa, was born at Ormiston, Haddingtonshire, on the 21st of December 1795, of humble parentage. He began as a gardener, but in 1814, when employed at High Leigh in Cheshire, offered himself to the London Missionary Society, and in 1816 was sent out to South Africa. After spending a year in Namaqua Land, with the chief Afrikaner, whom he converted, Moffat returned to Cape Town in 1819 and married Mary Smith (1795–1870), the daughter of a former employer, a remarkable woman and most helpful wife. In 1820 Moffat and his wife left the Cape and proceeded to Griqua Town, and ultimately settled at Kuruman, among the Bechuana tribes living to the west of the Vaal river. Here he worked as a missionary till 1870, when he reluctantly returned finally to his native land. He made frequent journeys into the neighbouring regions as far north as the Matabele country. The results of these journeys he communicated to the Royal Geographical Society (*Journal* xxv.–xxxviii. and *Proceedings* ii.), and when in England on furlough (1839–1843) he published his well-known *Missionary Labours and Scenes in South Africa* (1842). He translated the whole of the Bible and *The Pilgrim's Progress* into Sechwana. Moffat was builder, carpenter, smith, gardener, farmer, all in one, and by precept and example he succeeded in turning a horde of bloodthirsty savages into a "people appreciating and cultivating the arts and habits of civilized life, with a written language of their own." He met with incredible discouragement and dangers at first, which he overcame by his strong faith, determination and genial humour. It was largely due to him that David Livingstone, his son-in-law, took up his subsequent work. On his return to England he received a testimonial of £5000. He died at Leigh, near Tunbridge Wells, on the 9th of August 1883.

See *Lives of Robert and Mary Moffat*, by J. S. Moffat (1885); and C. S. Horne, *The Story of the L. M. S.* (1894).

MOFFAT, a burgh of barony, and police burgh, of Upper Annandale, Dumfriesshire, Scotland. Pop. (1901), 2153. It is situated 21 m. N.N.E. of Dumfries by road and 63 m. distant by the Caledonian railway, from both Edinburgh and Glasgow. It is the terminus of a branch line from Beattock, 2 m. distant. It has been famous for its sulphur and saline waters since the middle of the 18th century, and also enjoys great vogue as a holiday resort. The hills in the locality range from the adjacent Gallow Hill (832 ft.) to Hartfell (2651 ft.); about 5 m. north there is abundance of beautiful and varied scenery on the Annan, the Evan, the Birnock and the Moffat. The spa, a mile to the north of the town, was acquired by the burgh commissioners in 1898, and there are also spas at Hartfell (3½ m. north) and Garpel (2 m. south-west). Dumcrieff House, 2 m. south-west, is the seat of Lord Rollo.

MOGADOR (*Es-Sueira*), the most southern seaport on the Atlantic coast of Morocco, in 31° 50′ N., 9° 20′ W., the capital of the province of Háhá. Pop. (1908), about 20,000, of whom nearly a half are said to be Jews, and about 100 Europeans. The town stands from 10 to 20 ft. above high water on a projecting ridge of calcareous sandstone. In certain states of wind and sea it is turned almost into an island, and a sea-wall protects the road to Saffi. On the land side stretch miles of sand-dunes studded with broom, and beyond, the argan forests, distinctive of southern Morocco. Approached from this side the city bursts on the view like a mirage between sky and sea, and this perhaps entitles it to its name—Es-Sueira—"the picture." It is the best planned and cleanest town in the empire, and this combined with the climate, which is very equable, makes it a health resort, especially for consumptive patients. The mean temperature of the hottest month is 71°·06, and of the coldest month 58°·69. The rainfall varies between 13 and 20 in. annually. The water supply is carried by an overground conduit from a spring near

Diabat. The prosperity of Mogador is due to its commerce. The harbour is well sheltered from all winds except the south-west, but escape is difficult with the wind from that quarter, as the channel between the town and Mogador Island is narrow and hazardous. It is the best-built port of the sultanate and is generally second in point of trade, which is carried on mainly with Marseilles, London, Gibraltar and the Canaries, the principal exports being almonds, goat-skins, gums and olive-oil, and the principal imports cotton goods, sugar and tea. The exports were valued at £407,000 in 1900 and at £364,000 in 1906. The imports were worth £246,000 in 1900 and £368,000 in 1906. Shipping, 1900, 132,000 tons; 1906, 140,000 tons.

A place called Mogador is marked in the 1351 Portulan of the Laurentian library, and the map in Hondius's *Atlas minor* shows the island of Mogador, *I. Domegador*; but the origin of the present town is much more recent. Mogador was founded by Mohammed XVII. (bin Abd Allah) in 1760, and completed in 1770. The Portuguese called it after the shrine of Sidi Megdul, which lies towards the south half-way to the village of Diabat, and forms a striking landmark for seamen. In 1844 the citadel was bombarded by the French.

See A. H. Dyé, "Les Ports du Maroc," in *Bull. Soc. Geog. Comm. Paris* (1908), xxx. 313 sqq., and British Consular reports.

MOGILA, PETER (*c.* 1596–1647), metropolitan of Kiev from 1632, belonged to a noble Wallachian family. He studied for some time at the university of Paris, and first became a monk in 1625. He was the author of a *Catechism* (Kiev, 1645) and other minor works, but is principally celebrated for the *Orthodox Confession*, drawn up at his instance by the Abbot Kosslowski of Kiev, approved at a provincial synod in 1640, and accepted by the patriarchs of Constantinople, Jerusalem, Alexandria and Antioch in 1642–1643, and by the synod of Jerusalem in 1672. (See ORTHODOX EASTERN CHURCH.)

There are numerous editions of the *Confession* in Russian; it has been edited in Greek and Latin by Panagiotes (Amsterdam, 1662), by Hofmann (Leipzig, 1695), and by Kimmel (Jena, 1843), and there is a German translation by Frisch (Frankfort, 1727).

MOGILEV, a government of western Russia, situated on the upper Dnieper, between the governments of Vitebsk and Smolensk on the north and east, and Chernigov and Minsk on the south and west. In the north it is occupied by the watershed which separates the basins of the Dvina and the Dnieper, an undulating tract 650 to 900 ft. above sea-level, and covered nearly everywhere with forests. This watershed slopes gently to the south, to the valley of the Dnieper, which enters the government from the north-east and flows due south. The southern part of the government is flat and has much in common with the Polyesie of the government of Minsk; it is, however, more habitable, the marshes being less extensive. Mogilev is built up of Devonian deposits in the north, of Cretaceous in the east, and of Tertiary elsewhere, but generally is covered with a thick layer of Glacial and later alluvial deposits. Interesting finds from the Stone Age, as well as remains of the mammoth, have been made.

The soil is mostly sand, clay (brick-clay and potter's-clay are not uncommon), and peat-bogs, with a few patches of "black earth." The climate is harsh and wet, the average yearly temperature at the Gorki meteorological observatory being 40°·4 F. (14°·2 in January and 63°·8 in July); cold nights in summer are often the cause of bad crops. The government had 947,625 inhabitants in 1870, and in 1897, 1,706,511, of whom 861,533 were women, and 146,752 lived in towns. The estimated population in 1906 was 2,024,300. The population is mostly White Russian. Agriculture is their chief occupation. Out of the total area of 18,546 sq. m. 40 % is held in communal ownership by the peasants, 48 % is owned by landlords possessing more than 270 acres each, and 3½ % by small owners. Most of the private owners belong to the nobility. The principal crops are rye, oats, barley, buckwheat, potatoes, though wheat, beetroot, flax, hemp and tobacco are also grown. Paper, spirits, wire and nails, leather and tiles are the chief products of the manufactures. The government is divided into eleven districts, of which the chief towns with their populations in 1897 were: Mogilev-on-Dnieper, or Mogilev Gubernskiy (47,591 in 1900), Chausy (5550), Cherikov (5250), Homel or Gomel (45,081 in 1900), Gorki (6730), Klimovichi (4706), Mstislavl (10,382 in 1900), Orsha (13,161), Rogachev (9103), Staryi Bykhov (6354), and Syenno (4061).

This government was inhabited in the 10th century by the Slav tribes of the Krivichi and Radimichi. In the 14th century it became part of Lithuania, and afterwards of Poland. Russia annexed it in 1772.

MOGILEV ON THE DNIEPER, a town of Russia, capital of the government of Mogilev. Pop. (1900), 47,591, two-thirds Jews. It is situated on a hilly site on both banks of the Dnieper, 120 m. by rail S.W. of Smolensk. It is the see of an archbishop of the Orthodox Greek Church. The public buildings include the cathedral of the Orthodox Greek Church (founded by Catherine II. of Russia and Joseph II. of Austria in 1780), a Roman Catholic cathedral (built in 1692), an old castle, a museum, a church dating from 1620, and an old Tatar tower. The principal industries are tanneries. The commerce is mostly in the hands of Jews. Corn, salt, sugar and fish are brought from the south, whilst skins and manufactured wares, imported from Germany, are sent to the southern governments.

Mogilev is mentioned for the first time in the 14th century as a dependency of the Vitebsk, or of the Mstislavl principality. At the beginning of the 15th century it became the personal property of the Polish kings. But it was continually plundered—either by Russians, who attacked it six times during the 16th century, or by Cossacks, who plundered it three times. In the 17th century its inhabitants, who belonged to the Orthodox Greek Church, suffered much from the persecutions of the United Greek Church. In 1654 it surrendered to Russia, but in 1661 the Russian garrison was massacred by the inhabitants. In the 18th century the town was taken several times by Russians and by Swedes, and in 1708 Peter the Great ordered it to be destroyed by fire. It was annexed to Russia in 1772. Near here the French under Davoût defeated the Russians under Bagration on the 23rd of July 1812.

MOGILEV ON THE DNIESTER, a town of Russia, in the government of Podolia, on the left bank of the Dniester, 57 m. E.S.E. of Kamenets-Podolsk. Pop. (1900), 25,141, nearly one-half Jews; the remainder are Little Russians, Poles and a few Armenians. The Little-Russian inhabitants carry on agriculture, gardening, wine-growing and mulberry culture. The Jews and Armenians are engaged in a brisk trade with Odessa, to which they send corn, wine, spirits and timber, floated down from Galicia, as well as with the interior, to which they send manufactured wares imported from Austria.

Mogilev, named in honour of the Moldavian hospodar Mohila, was founded by Count Potocki about the end of the 16th century. Owing to its situation on the highway from Moldavia to the Ukraine, at the passage across the Dnieper, it developed rapidly. For more than 150 years its possession was disputed between the Cossacks, the Poles and the Turks. It remained in the hands of the Poles, and was annexed to Russia in 1795.

MOGUL, MOGHAL, or MUGHAL, the Arabic and Persian form of the word Mongol, usually applied to the Mahommedan Empire in India, which was founded by Baber. In consequence the name is applied to all foreign Mahommedans from the countries on the west and north-west of India, except the Pathans. The Great Mogul is the name given to the Mogul emperors of Delhi by the Portuguese and subsequently by Europeans generally.

MOHÁCS, a market town of Hungary, in the county of Baranya, 115 m. S. of Budapest. Pop. (1900), 15,812. It is situated on the right bank of the Danube, and carries on a brisk trade in wine and the agricultural produce of the neighbourhood. Amongst its principal buildings are an old castle and the summer palace of the bishop of Pécs. Mohács is famous in the history of Hungary by the two fateful battles which took place in the plain situated about 3 m. south-west of the town, and marked the beginning and the close of the Turkish dominion in Hungary. In the first (Aug. 29, 1526) the Hungarian army under Louis II.

was annihilated by the Ottoman forces led by Soliman the Magnificent. In the second (Aug. 12, 1687) the Austrians under Charles of Lorraine gained a decisive victory over the Turks, whose power was afterwards still further broken by Prince Eugene of Savoy.

MOHAIR, the hair of a variety of goat originally inhabiting the regions of Asiatic Turkey of which Angora is the centre, whence the animal is known as the Angora goat. The Arabic *muḥayyar*, from which the word came into English probably through the Ital. *moccacaro* or Fr. *mocayart*, meant literally, "choice" or "select," and was applied to cloth made of goats' hair. In the 17th century the word, which before appears in such forms as *mocayare* or *mokaire*, became corrupted by connexion with "hair," cf. "cray-fish" from *écrevisse*. From the English "mohair" the French adapted *moire*, a watered silk fabric.

The typical mohair fibre is 7 to 8 in. long, very lustrous owing to its physical structure (which although akin to wool is different in that the wool scales are indicated only instead of being fully developed, while the fibre is always solid), $\frac{1}{600}$ to $\frac{1}{800}$ of an inch in diameter, of a soft elastic handle, and usually of a clear white transparent colour. The staples of which the fleece is formed should be uniform in length and clearly defined, naturally lending themselves to a good "spin"—a difficult attainment in the case of mohair (see Woollen and Worsted Manufactures). There are many varieties of mohair, from the first qualities as here defined to lower qualities, of a kempy, unsatisfactory character. Thus, in Constantinople, the chief centre of the Turkey mohair trade, a large variety of fleeces is recognized. For example, from the Lake Van district a distinctly inferior kind known as "Van" mohair is obtained, while other districts produce varieties ranging from Van up to the typical quality described above.

The animal from which mohair was originally obtained was a finely-bred Angora goat. Owing to the demand for raw material exceeding the supply, from 1820 onwards there has been a great deal of crossing of the well-bred Angora with the common kind of goat: in fact it has been said that by 1863 the original Angora had practically disappeared. The growing demand for mohair further resulted in attempts on a commercial scale to introduce the goat into South Africa—where it was crossed with the native goat—the United States, Australia, and later still New Zealand. Perhaps the introduction of the Angora into Australia and New Zealand may in part be due to its value as a scrub and blackberry browser; these growths being the "pests" of the two respective countries.

The manufacture of fabrics from mohair—as in the case of alpaca and cashmere—was in the first instance due to the genius of the rearers of the goat. It would, indeed, be interesting to know if the present day mohair goods—often styled "alpacas" really had their origin in the earlier products of Asia Minor. That fabrics of mohair were in use in England early in the 18th century is obvious from Pope's allusion:—

> "And, when she sees her friend in deep despair,
> Observes how much a chintz exceeds mohair."

Raw mohair was first exported from Turkey to England about 1820, and from that date onwards marked strides were made in its manufacture into useful yarns and fabrics. England has always had, and still maintains, supremacy in this manufacture. Practically the whole of both the Turkish and Cape clips is at least converted into yarn in Yorkshire mills. Quantities of these yarns are also woven into dress goods, dust cloakings, pile fabrics, imitation furs, &c., in Yorkshire, but even greater quantities of mohair yarn are exported to Russia, Germany, Austria, &c., to be converted into astrakans, ordinary braids, brush braids, &c. In the first decade of the 20th century the mohair braid trade received a blow from the introduction of artificial silk.

The history of the introduction of the Angora goat from Asia Minor into the other countries mentioned is as follows. In 1838 pure bred Angoras were introduced into Cape Colony—cashmeres having been previously tried and found unsatisfactory. These pure-bred goats crossed with the common goat laid the basis of the Cape flocks. In 1856–1857 other importations of pure-bred goats were made. From 1868 to 1897 further importations were made, but these were not of the pure-bred goat and consequently were not so valuable. It should here be noted that the Cape flock-owner clips twice—the summer clip yielding a staple which should be of not less than 7 in., and the winter clip a staple which should be of not less than 3 in. to 4 in. Bradford from time to time has objected to the winter clip as being too short, but this clip seems to have established itself and at least once during recent years has been as saleable as the summer clip. The introduction of Angoras into the United States took place in 1849. Other importations of goats from Asia Minor were made between 1857 and 1880, and interchanges of blood also took place between the United States and Cape Colony. Between 1856 and 1875 some three hundred goats were introduced into Australia. Other importations from Cape Colony and the United States have also been made from time to time, and it seems at least possible, if not probable, that Australia may yet find the Angora goat an important asset.

From the following statistics relating to mohair it will be realized that the mohair supply practically comes from two sources, viz. Turkey in Asia and South Africa:—

Country.	*No. of Goats.*	*Yield of Hair.*
Asia Minor	3½ to 4 millions.	11 to 12,000,000 lb.
South Africa	4 millions.	12 to 14,000,000 lb.
United States	800,000	1,600,000 lb.
Australia	30,000	——

The price per lb of mohair has varied from 4s. 1d. in 1870 to 13d. or 14d. in 1903, and it is interesting to note that the shipments from Turkey to England follow these price fluctuations in a most curious manner.

Of the consumers of English mohair yarns Russia takes from 15 to 25%, and the continent of Europe as a whole a very large percentage of the total mohair yarn production of Bradford.

MOHAVE (corrupted from *hamok-habi*, "three mountains," their native name, with reference to three peaks, which form a prominent feature of their country), a tribe of North American Indians of Yuman stock. They have always lived along both banks of the lower Colorado river, in Arizona and California.

MOHAWK, a tribe of North American Indians, the chief people of the Iroquois confederacy. The name probably means "man-eaters"; they call themselves *Kaniengehaga*, "flint people." Their villages were in the valley of the Mohawk river, New York. Their territory extended northward to the St Lawrence and southward to the Delaware river and Catskill Mountains. They were thus early in touch with Dutch and English, and were the first Indians to obtain firearms. In the War of Independence they fought with the English, and finally took refuge in Canada, where most of them have remained.

See Indians, North American. For Mohawk cosmology see *21st Annual Report Bureau Amer. Ethnol.* (1899–1900).

MOHICAN, MAHICAN AND MOHEGAN, the first two the alternative names of an important tribe and confederacy of North American Indians of Algonquian stock, and the last a dialectic form of the name applied to a branch tribe. The Mohicans inhabited the Hudson valley, and their domain extended into Massachusetts. The Mohicans were called by the French *Loups* (wolf Indians), a translation of "Mohican." At first their council-fire was at Schodac, on an island near Albany, and they were grouped in forty villages. In consequence of attacks by the Mohawks, they moved their council-fire to what is now Stockbridge, Massachusetts, in 1664; in 1730 many migrated to the Susquehanna valley, Pennsylvania, and became absorbed into the Delawares. In 1736 those left in Massachusetts were placed on a reservation at Stockbridge, and called by that name. A few of these Stockbridge Indians, who may be truly called "the last of the Mohicans," are now settled, with some of the Munsees, on a reservation at Green Bay, Wisconsin. The Mohegans, originally an offshoot of the Mohican, lived on Thames river, Connecticut, their county extending into Massachusetts and including Rhode Island. In 1637, on the destruction of the Pequots, an offshoot of the Mohegans, the Mohegans claimed their country too, and thus the territorial power of the two tribes was consolidated under one Mohegan chief. For some time the Mohegans remained the supreme Indian people of southern New England. Eventually they sold most of their lands and centred in a small reservation on Thames river. They have now practically become extinct.

MOHL, HUGO VON (1805–1872), German botanist, was born at Stuttgart on the 8th of April 1805. He was a son of the Württemberg statesman Benjamin Ferdinand von Mohl (1766–1845), the family being connected on both sides with the higher class of state officials of Württemberg. While a pupil at the gymnasium he pursued botany and mineralogy in his leisure time, till in 1823 he entered the university of Tübingen. After graduating with distinction in medicine he went to Munich, where he met a distinguished circle of botanists, and found ample material for research. This seems to have determined his career as a botanist, and he started in 1828 those anatomical investigations which continued till his death. In 1832 he was appointed professor of botany in Tübingen, a post which he never left. Unmarried, his pleasures were in his laboratory and library, and in perfecting optical apparatus and microscopic preparations, for which he showed extraordinary manual skill. He was largely a self-taught botanist from boyhood, and, little influenced in his opinions even by his teachers, preserved always his independence of view on scientific questions. He received many honours during his lifetime, and was elected foreign fellow of the Royal Society in 1868. Von Mohl's writings cover a period of forty-four years; the most notable of them were republished in 1845 in a volume entitled *Vermischte Schriften*. (For lists of his works see *Botanische Zeitung*, 1872, p. 576, and *Royal Soc. Catalogue*, 1870, vol. iv.) They dealt with a variety of subjects, but chiefly with the structure of the higher forms, including both rough anatomy and minute histology. The word "protoplasm" was his suggestion; the nucleus had already been recognized by R. Brown and others, but von Mohl showed in 1844 that the protoplasm is the source of those movements which at that time excited so much attention. He recognized under the name of "primordial utricle" the protoplasmic lining of the vacuolated cell, and first described the behaviour of the protoplasm in cell-division. These and other observations led to the overthrow of J. M. Schleiden's theory of origin of cells by free-cell-formation. His contributions to knowledge of the cell-wall were no less remarkable; he held the view now generally adopted of growth of cell-wall by apposition. He first explained the true nature of pits, and showed the cellular origin of vessels and of fibrous cells; he was, in fact, the true founder of the cell theory. Clearly the author of such researches was the man to collect into one volume the theory of cell-formation, and this he did in his treatise *Die vegetabilische Zelle* (1851), a short work translated into English (Ray Society, 1852). Von Mohl's early investigations on the structure of palms, of cycads, and of tree-ferns permanently laid the foundation of all later knowledge of this subject: so also his work on *Isoetes* (1840). His later anatomical work was chiefly on the stems of dicotyledons and gymnosperms; in his observations on cork and bark he first explained the formation and origin of different types of bark, and corrected errors relating to lenticels. Following on his early demonstration of the origin of stomata (1838), he wrote a classical paper on their opening and closing (1850). In 1843 he started in conjunction with F. Schlechtendal the weekly *Botanische Zeitung*, which he jointly edited till his death. He was never a great writer of comprehensive works; no text-book exists in his name, and it would indeed appear from his withdrawal from co-operation in W. F. B. Hofmeister's *Handbuch* that he had a distaste for such efforts. In his latter years his productive activity fell off, doubtless through failing health, and he died suddenly at Tübingen on the 1st of April 1872.

See Sachs, *History of Botany*, p. 292, &c.; De Bary, *Botanische Zeitung* (1872), p. 561; *Proc. Roy. Soc.*, xxiii. 1; *Allgemeine Deutsche Biographie*, xxii. 55. (F. O. B.)

MOHL, JULIUS VON (1800–1876), German Orientalist, brother of Hugo von Mohl (*q.v.*), was born at Stuttgart on the 25th of October 1800. Having studied theology at Tübingen (1818–1823), he abandoned the idea of entering the Lutheran ministry, and in 1823 went to Paris, at that time, under Silvestre De Sacy, the great European school of Eastern letters. From 1826 to 1833 he was nominally professor at Tübingen, but had permission to continue his studies abroad, and he passed some years in London and in Oxford. In 1826 he was charged by the French government with the preparation of an edition of the *Shah Nama* (*Livre des rois*), the first volume of which appeared in 1838, while the seventh and last was left unfinished at his death, being completed by Barbier de Meynard. Discerning this to be his life's work, he resigned his chair at Tübingen in 1834, and settled permanently in Paris. In 1844 he was nominated to the academy of inscriptions, and in 1847 he became professor of Persian at the Collège de France. But his knowledge and interest extended to all departments of Oriental learning. He served for many years as secretary, and then as president of the Société Asiatique. His annual reports on Oriental science, presented to the society from 1840 to 1867, and collected after his death in Paris on the 3rd of January 1876, under the title *Vingt-sept ans d'histoire des études orientales* (Paris, 1879), are an admirable history of the progress of Eastern learning during these years. Concerning the discoveries at Nineveh he wrote *Lettres de M. Botta sur les découvertes à Khorsabad* (1845). He also published anonymously, in conjunction with Justus Olshausen (1800–1882), *Fragments relatifs à la religion de Zoroastre* (Paris, 1829); *Confucii Chi-king sive liber carminum, ex latina P. Lacharmi interpretatione* (Stuttgart, 1830); and an edition of Y-King, *Antiquissimus Sinarum liber, ex interpretatione P. Regis* (Stuttgart, 1834–1839).

His wife Mary (1793–1883), daughter of Charles Clarke, had passed a great part of her early life in Paris, where she was very intimate with Madame Récamier, before their marriage in 1847, and for nearly forty years her house was one of the most popular intellectual centres in Paris. Madame Mohl's friends included a large number of Englishmen and Englishwomen. She died in Paris on the 14th of May 1883. Madame Mohl wrote *Madame Récamier, with a Sketch of the History of Society in France* (London, 1862).

See Kathleen O'Meara, *Madame Mohl, her Salon and Friends* (1885); and M. C. M. Simpson, *Letters and Recollections of Julius and Mary Mohl* (1887).

Mohl's elder brother, Robert von Mohl (1799–1875), was a well-known jurist and statesman. From 1824 to 1845 he was professor of political sciences at the university of Tübingen, losing his position because of some frank criticisms which brought him under the displeasure of the authorities of Württemberg. In 1847 he was a member of the parliament of Württemberg, and in the same year he was appointed professor of law at Heidelberg; in 1848 he was a member of the German parliament which met at Frankfort, and for a few months he was minister of justice. His later public life was passed in the service of the grand-duke of Baden, whom he represented as ambassador in Munich from 1867 to 1871. He died in Berlin on the 5th of November 1875. Among his numerous writings may be mentioned, *Die deutsche Polizeiwissenschaft nach den Grundsätzen des Rechtsstaats* (Tübingen, 1832–1834, and again 1866); *Geschichte und Literatur der Staatswissenschaften* (Erlangen, 1855–1858); *Encyklopädie der Staatswissenschaften* (Tübingen, 1859, again 1881); and *Staatsrecht, Völkerrecht und Politik* (Tübingen, 1860–1869).

See Mohl's own *Lebenserinnerungen* (Leipzig, 1901); and H. Schulze, *Robert von Mohl, Ein Erinnerungsblatt* (Heidelberg, 1886).

Another brother, Moritz von Mohl (1802–1888), entered official life at an early age and was a member of the Frankfort parliament, and later of the parliament of Württemberg and of the imperial Reichstag. He was a voluminous writer on economic and political questions.

MÖHLER, JOHANN ADAM (1796–1838), German theologian, was born at Igersheim in Württemberg on the 6th of May 1796, and after studying philosophy and theology in the lyceum at Ellwangen, entered the university of Tübingen in 1817. Ordained to the priesthood in 1819, he was appointed to a curacy at Riedlingen, but speedily returned as "repetent" to Tübingen, where he became *privatdozent* in 1822, extraordinary professor of theology in 1826 and ordinary professor in 1828. His lectures drew large audiences, including many Protestants. The controversies excited by his *Symbolik* (1832) proved so unpleasant that in 1835 he accepted a call to the university of Munich. In 1838 he was appointed to the deanery of Würzburg, but died shortly afterwards (April 12, 1838).

Möhler wrote *Die Einheit in der Kirche oder das Prinzip des Katholicismus* (Tübingen, 1825); *Athanasius der Grosse u. d. Kirche seiner Zeit* (2 vols., Mainz, 1827); *Symbolik, oder Darstellung der dogmatischen Gegensätze der Katholiken u. Protestanten nach ihren öffentlichen Bekenntnissschriften* (Mainz, 1832; 8th ed., 1871–1872; Eng. trans. by J. B. Robertson, 1843); and *Neue Untersuchungen der Lehrgegensätze zwischen den Katholiken u. Protestanten* (1834). His *Gesammelte Schriften u. Aufsätze* were edited by Döllinger in 1839; his *Patrologie* by Reithmayr, also in 1839; and a *Biographie* by B. Wörner was published at Regensburg in 1866. It is with the *Symbolik* that his name is chiefly associated; the interest excited by it in Protestant circles is shown by the fact that within two years of its appearance it had elicited three replies of considerable importance, those namely of F. C. Baur, P. K. Marheineke and C. J. Nitzsch. But, although characterized by learning and acuteness, as well as by considerable breadth of spiritual sympathy, it cannot be said to have been accepted by Catholics themselves as embodying an accurate objective view of the actual doctrine of their church. The liberal school of thought of which Möhler was a prominent exponent was discouraged in official circles, while Protestants, on the other hand, complain that the author failed to grasp thoroughly the significance of the Reformation as a great movement in the spiritual history of mankind, while needlessly dwelling on the doctrinal shortcomings, inconsistencies and contradictions of its leaders.

MOHMAND, a Pathan tribe who inhabit the hilly country to the north-west of Peshawar, in the North-West Frontier Province of India. They are one of the strongest tribes on the border after the Afridis and Waziris, and have given much trouble to the government of India. The country of the Mohmands may be defined roughly as bounded on the E. by British districts from near Jamrud to Fort Abazai, and thence by the Utman Khel country; on the N. by Bajour; on the W. by Kunar; and on the S. by the territories of the Shinwari and Afridi; area, about 1200 sq. m. The Indo-Afghan boundary line now runs through the Mohmand country; but the amir of Afghanistan formerly claimed allegiance from all the Mohmands, and only handed over the greater part of this tract to the British by the Durand Agreement of 1893. The government has given assurances to the Burhan Khel, Dawezai, Halimzai, Isa Khel, Tarakzai and Utmanzai sections of the Mohmands that they will not suffer by the severance of their ancient connexion with Afghanistan; and these are known as the Assured Clans. The tribe are Afghans by descent, and are more akin to the Yusafzais than any of their neighbours. The aspect of the Mohmand hills is exceedingly dreary, and the eye is everywhere met by dry ravines between long rows of rocky hills and crags, scantily clothed with coarse grass, scrubwood and the dwarf palm. In summer great want of water is felt, and the desert tracts radiate an intolerable heat. This, coupled with the unhealthiness of the lowlands, probably accounts for the inferior physique of the Mohmands as compared with their Afridi and Shinwari neighbours, who in summer retire to the cool highlands of Tirah and the Safed Koh. The crops in the Mohmand hills are almost entirely dependent on the winter and autumn rains, and should these fail there is considerable distress; but the Mohmands supplement this source of livelihood by a through trade on rafts along the Kabul river between the British districts and the hill-country beyond them. The exports are wax, hides, ghi and rice from Kunar, and iron from Bajour; the imports are salt, cloth, paper, soap, tea, indigo, sugar, grain, tobacco, needles, scissors and other manufactures of civilization. The Mohmands are characterized by great pride and haughtiness, they bear a bad reputation for treachery and ruthless cruelty, and are not as brave as their Afridi neighbours. They number some 18,000 fighting men, giving roughly a population of 65,000; but all the clans would never act together under any circumstances. British punitive expeditions have been sent against the Mohmands in 1851–52, 1854, 1864, 1879, 1880, but the principal operations were those of 1897. (T. H. H.*)

Campaign of 1897.—The year 1897 witnessed an almost general outbreak among the tribes on the north-west frontier of India. The tribes involved were practically independent, but the new frontier arranged with the amir of Afghanistan, and demarcated by Sir Mortimer Durand's commission of 1893–1894, brought them within the British sphere of influence. The great dread of these high-spirited mountaineers was annexation, and the hostility shown during the demarcation led to the Waziri expedition of 1894. Other causes, however, contributed to bring about the outbreak of 1897. The easy victory of the Turks over the Greeks gave rise to excitement throughout the Mahommedan world, and the publication by the amir of Afghanistan, in his assumed capacity of king of Islam, of a religious work, in portions of which fanatical antipathy to Christians was thinly veiled, aroused a warlike spirit among the border Mahommedans. The growing unrest was not recognized, and all appeared quiet, when, on the 10th of June 1897, a detachment of Indian troops escorting a British frontier officer was suddenly attacked during the mid-day halt in the Tochi valley, where, since the Waziri expedition of 1894–95, certain armed posts had been retained by the government of India. On the 29th of July, with equal suddenness, the fortified posts at Chakdara and Malakand, in the Swat valley, which had been held since the Chitral expedition of 1895, were for several days fiercely assailed by the usually peaceful Swatis under the leadership of the Mad Mullah. On the 8th of August the village of Shabkadar (Shankarghar), within a few miles of Peshawar, and in British territory, was raided by the Mohmands, while the Afridis besieged the fortified posts on the Samana ridge, which had been maintained since the expeditions of 1888 and 1891. Finally, the Afridis, within a few days, captured all the British posts in the Khyber Pass. A division commanded by Major-General Sir Bindon Blood was assembled at Nowshera. The post at Malakand was reached on the 1st of August, and on the following day Chakdara was relieved. The punishment of the Afridis was deferred till the preparations for the Tirah campaign (see TIRAH) could be completed. The Mohmands, however, could be immediately dealt with, and against them the two brigades of Sir Bindon Blood's division advanced from Malakand simultaneously with the movement of another division under Major-General (afterwards Sir Edmund) R. Elles from Peshawar; it was intended that the two columns should effect a junction in Bajour. About the 6th of September the two forces advanced, and Major-General Blood reached Nawagai on the 14th of September, having detached a brigade to cross the Rambat Pass. This brigade being sharply attacked in camp at Markhanai at the foot of the pass on the night of the 14th, was ordered to turn northwards and punish the tribesmen of the Mamund valley. On the 15th Brigadier-(afterwards Major-) General Jeffreys camped at Inayat Killa, and on the following day he moved up the Mamund valley in three columns, which met with strong resistance. A retirement was ordered, the tribesmen following, and when darkness fell the general, with a battery and a small escort, was cut off, and with difficulty defended some buildings until relieved. The casualties in this action numbered 149. This partial reverse placed General Blood in a position of some difficulty. He determined, however, to remain at Nawagai, awaiting the arrival of General Elles, and sent orders to General Jeffreys to prosecute the operations in the Mamund valley. From the 18th to the 23rd these operations were carried on successfully, several villages being burned, and the Mamunds were disheartened. Meanwhile, the camp at Nawagai was heavily attacked on the night of the 20th by about 4000 men belonging to the Hadda Mullah's following. The attack was repulsed with loss, and on the 21st Generals Blood and Elles met at Lakarai. The junction having been effected, the latter, in accordance with the scheme, advanced to deal with the Upper Mohmands in the Jarobi and Koda Khel valleys, and they were soon brought to reason by his well-conducted operations. The work of the Peshawar division was now accomplished, and it returned to take part in the Tirah campaign. Its total casualties were about 30 killed and wounded. On the 22nd General Blood joined General Jeffreys, and on the 24th he started with his staff for Panjkora. On the 27th General Jeffreys resumed punitive operations in the Mamund valley, destroying numerous villages. On the 30th he encountered strong opposition at Agrah, and had 61 casualties. On the 2nd of October General Blood arrived at Inayat Killa with reinforcements, and on the 11th the Mamunds tendered their submission. The total British loss in the Mamund valley was 282 out of a force which never exceeded 1200 men. After marching into Buner, and revisiting the scenes of the Umbeyla expedition of 1863, the Malakand field-force was broken up on the 21st of January. The objects of the expedition were completely attained, in spite of the great natural difficulties of the country. The employment of imperial service troops with the Peshawar column marked a new departure in frontier campaigns.

(C. J. B.)

MOHONK LAKE, a summer settlement at the northern end of Lake Mohonk, Ulster county, New York, U.S.A., about 14 m. N.W. of Poughkeepsie. It is served from New Paltz, about 1 m. S.E. (about 5½ m. by stage), by the Wallkill Valley railway, a branch of the West Shore. The lake is a small body of water, picturesquely situated 1245 ft. above the sea-level, on Sky Top Mountain (1542 ft.), one of the highest peaks of the Shawangunk range. The highest point of Sky Top lies just east of the south end of the lake; close by, to the west, Eagle Cliff rises to a height of 1412 ft. The development of this beautiful region into a summer resort and the holding of Indian and arbitration conferences here have been due to Albert Keith Smiley (b. 1828), a graduate of Haverford College (1849), who conducted an English and classical academy in Philadelphia in 1853–1857, was principal of the Oak Grove academy at Vassalboro, Maine, in 1858–1860, was principal and superintendent of the Friends' school at Providence, Rhode Island, in 1860–1879, and became a member of the United States Board of Indian Commissioners in 1879. In 1869 he bought, at the northern end of Lake Mohonk, a tract of land on which he built a large hotel. Here, in October 1883, the first Conference of the Friends of the American Indian met; these conferences have since been held annually, their scope being enlarged in 1904 to include consideration of the condition of "other dependent peoples"—*i.e.* the natives of the Philippines, Porto Rico and Hawaii. The first conference on international arbitration was held here in June 1895.

MOHR, KARL FRIEDRICH (1806–1879), German pharmacist, son of a well-to-do druggist in Coblentz, was born on the 4th of November 1806. Being a delicate child he received much of his early education at home, in great part in his father's laboratory. To this may be traced much of the skill he showed in devising instruments and methods of analysis. At the age of twenty-one he began to study chemistry under Leopold Gmelin, and, after five years spent in Heidelberg, Berlin and Bonn, returned with the degree of Ph.D. to join his father's establishment. On the death of his father in 1840 he succeeded to the business, retiring from it for scientific leisure in 1857. Serious pecuniary losses led him at the age of fifty-seven to become a *privatdozent* in Bonn, where in 1867 he was appointed, by the direct influence of the emperor, extraordinary professor of pharmacy. He died at Bonn on the 28th of September 1879. Mohr was the leading scientific pharmacist of his time in Germany, and he was the author of many improvements in analytical processes. His methods of volumetric analysis were expounded in his *Lehrbuch der chemisch-analytischen Titrirmethode* (1855), which won the special commendation of Liebig and has run through many editions. His *Geschichte der Erde, eine Geologie auf neuer Grundlage* (1866), also obtained a wide circulation. In a paper "Über die Natur der Wärme," published in the *Zeitschrift für Physik* in 1837, he gave one of the earliest general statements of the doctrine of the conservation of energy in the words: "besides the 54 known chemical elements there is in the physical world one agent only, and this is called Kraft (energy). It may appear, according to circumstances, as motion, chemical affinity, cohesion, electricity, light and magnetism; and from any one of these forms it can be transformed into any of the others."

MOHS, FRIEDRICH (1773–1839), German mineralogist, was born at Gernrode in the Harz Mountains, on the 29th of January 1773. He was educated at Halle, and at the mining academy at Freiburg. He spent much time in Austria in studying mineralogy and mining, and became professor of mineralogy at Gratz in 1812. On the death of Werner in 1817, he was appointed to the chair of mineralogy in the mining academy of Freiburg, and in 1826 he became professor of mineralogy and superintendent of the Imperial Cabinet at Vienna. His great work was the *Grundriss der Mineralogie* (Eng. trans. *Treatise on Mineralogy*, by Wilhelm Haidinger, 1825). He died at Agardo, near Belluno, Italy, on the 29th of September, 1839.

MOHUN, CHARLES MOHUN, 4th Baron (*c.* 1675–1712), was the son of the 3rd Baron Mohun, who died in October 1677 as the result of a wound received while acting as second in a duel. The boy had no regular guardian, and before he was seventeen he had earned an unpleasant notoriety in London for rowdyism and brawling, had fought a duel and had been tried on a charge of murder. His friend, Captain Richard Hill, a roystering young officer, was in love with the actress Mrs Bracegirdle, and thought William Mountfort, the actor, to be his successful rival. On the night of the 9th of December 1692 Mohun assisted Hill to attempt the actress's abduction. The attempt failed, and Mohun and Hill then escorted Mrs Bracegirdle to her house, and subsequently remained together outside drinking till the appearance of Mountfort, who lived close at hand. Greetings were exchanged between Mohun and Mountfort, and the latter made a disparaging remark about Hill, who either without warning (according to Mountfort's deathbed statement) or in fair fight (according to other evidence) ran Mountfort through the body, and then absconded. Mohun was arrested and put on trial in Westminster Hall before his peers for murder as an accessory before the fact (1693), but by an overwhelming majority the peers found him not guilty. This verdict has been severely criticized, notably by Macaulay, who saw in it merely a gross instance of class favouritism. But a careful examination of the evidence (in the *State Trials*) justifies the decision, and establishes the presumption that the fight was a fair one. In 1699 Mohun was put on his trial for another alleged murder, but was unanimously and quite justly acquitted. His boon companion, Edward Rich, earl of Warwick (1673–1701), who was tried on a separate indictment for the same crime, was found guilty of manslaughter. On this occasion Mohun expressed regret for his past life, and he seems subsequently to have made a genuine attempt to alter his ways and to have taken a practical interest in public affairs. But in 1712 his violent temper again got the better of him, and he forced the 4th duke of Hamilton, with whom he had been at law for some years, into a desperate duel in Hyde Park in the early hours of the 15th of November, in which both combatants were killed. Thackeray has utilized this incident in *Esmond*. Lord Mohun had no issue, and on his death the barony, which was created in 1628 in favour of his great-grandfather John Mohun (*c.* 1592–1640), became extinct.

See *The Whole Life and History of My Lord Mohun and the Earl of Warwick* (London, 1711); J. Evelyn, *Diary and Correspondence*; Historical Manuscripts Commission, 11th report, appendix v. (Dartmouth MSS.); G. C. Boase and W. P. Courtney, *Bibliotheca cornubiensis* (1874–1882); Howell, *State Trials*; and Colley Cibber, *Apology*, edited by R. W. Lowe (1889).

MOHUN, MICHAEL (*c.* 1625–1684), English actor, played at the Cockpit in Drury Lane before the Civil War. He served on the king's side with credit and was promoted captain, and subsequently, in Flanders, major. At the Restoration he returned with Charles II. and took up his former profession, playing a great variety of parts, usually as second to Charles Hart.

MOHUR, the name of a Persian gold coin, used in India from the 16th century. The word is taken from the Persian *muhr*, a seal or ring. Between 1835 and 1891 a gold coin, also called a "mohur," was struck by the government of British India and was of the nominal value of 15 rupees. On the establishment of a gold standard in India in 1899, on the basis of 16d. a rupee, the British sovereign was declared legal tender and the mohur was thus superseded.

MOIDORE, (a corruption of the Portuguese *moeda d'ouro*, literally, money of gold), the name of a gold Portuguese coin, coined from 1640 to 1732. This was of the sterling value of 13s. 5½d. It is the double *moida d'ouro*, of the value of 4800 reis in 1688, that was current in western Europe and the West Indies for a long period after it ceased to be struck. It was the principal coin current in Ireland at the beginning of the 18th century, and spread to the west of England. At the same period it was current in the West Indies, particularly in Barbados. It was rated in English money at 27s.

MOIR, DAVID MACBETH (1798–1851), Scottish physician and writer, was born at Musselburgh on the 5th of January 1798. He studied medicine at Edinburgh University, taking his degree in 1816. Entering into partnership with a Musselburgh doctor he practised there until his death on the 6th of July 1851. He was a contributor of both prose and verse to the magazines, and particularly, with the signature of "Delta," to *Blackwood's*. A collection of his poetry was edited in 1852 by Thomas Aird. Among his publications were the famous *Life of Mansie Wauch, Tailor* (1828), which shows his gifts as a humorist, *Outlines of the Ancient History of Medicine* (1831), and *Sketch of the Poetical Literature of the Past Half Century* (1851).

MOISSAC, a town of south-western France, capital of an arrondissement in the department of Tarn-et-Garonne, 17 m. W.N.W. of Montauban on the Southern railway between Bordeaux and Toulouse. Pop. (1906) town, 4523; commune, 8218. Moissac stands at the foot of vine-clad hills on the right bank of the Tarn; it is divided into two parts by the lateral canal of the Garonne, which crosses the Tarn by way of an aqueduct a short distance above the town. It contains little of note except the abbey-church of St Pierre, a building of the 15th century with a porch of the 12th century which is decorated with elaborate Romanesque carving unsurpassed in France. The cloister of the early 12th century adjoining the north side of the church is also one of the finest of its kind. Romanesque in character, it has pointed arches resting alternately on single and clustered columns with sculptured capitals. Among other remains of the abbey is the abbot's palace, which contains two halls of the Romanesque period. St Martin, the oldest of the other churches of Moissac, dates from before the year 1000. The town has a sub-prefecture, a tribunal of first instance, a communal college for boys, a library and a museum. Trade is in oil, wine, eggs, wool, poultry and fruit (peaches, apricots, &c.).

The town owes its origin to an abbey probably founded in the 7th century by St Amand, the friend of Dagobert. After being devastated by the Saracens, the abbey was restored by Louis of Aquitaine, son of Charlemagne. Subsequently it was made dependent on Cluny, but in 1618 it was secularized by Pope Paul V., and replaced by a house of Augustinian monks, which was suppressed at the Revolution. The town, which was erected into a commune in the 13th century, was taken by Richard Cœur de Lion and by Simon de Montfort.

MOISSAN, HENRI (1852–1907), French chemist, was born at Paris on the 28th of September 1852. Educated at the Museum of Natural History, he was successively professor of toxicology (1886) and of inorganic chemistry (1889) at the School of Pharmacy, and of general chemistry at the Sorbonne (1900). In 1886 he succeeded in obtaining the element fluorine in the free state by the electrolysis of potassium fluoride and anhydrous hydrofluoric acid at a low temperature. Thence he was led to study the production of carbon in its three varieties and to attempt the artificial preparation of diamond, of which he was able to make some minute specimens (see GEMS, § *Artificial*). In connexion with these experiments he developed the electric furnace as a convenient means of obtaining very high temperatures in the laboratory; and by its aid he prepared many new compounds, especially carbides, silicides and borides, and melted and volatilized substances which had previously been regarded as infusible. For his preparation of fluorine he was awarded the Lacase prize in 1887, and in 1906 he obtained the Nobel prize for chemistry. He died in Paris on the 20th of February 1907.

His published works include *Le four électrique* (1897), and *Le fluor et ses composés* (1900), besides numerous papers in the *Comptes rendus* and other scientific periodicals. A *Traité de chimie minérale* in five volumes was published under his direction in 1904–1906.

MOJI, a town of Japan, on the Kiushiu side of the Shimonoseki Strait. The strait being only 1 m. in width, Moji and Shimonoseki would be practically the same port did not the swiftness of the current along the latter shore make it convenient for vessels to anchor off Moji. Moji is one of the places voluntarily opened by the Japanese for purposes of direct export. It is the starting-point of the Kiushiu railway, and as there is abundance of coal in its neighbourhood, it has become a town of considerable importance. In 1890 it was little more than a hamlet, but it had in 1901 a population of 25,274, and a considerable foreign trade.

MOJSISOVICS VON MOJSVAR, JOHANN AUGUST GEORG EDMUND (1839–1907), Austro-Hungarian geologist and palaeontologist, son of the surgeon Georg Mojsisovics von Mojsvar (1799–1860), was born at Vienna on the 18th of October 1839. He studied law in Vienna University, taking his doctor's degree in 1864, and in 1867 he entered the Geological Institute, becoming chief geologist in 1870 and vice-director in 1892. He retired in 1900, and died at Mallnitz on the 2nd of October 1907. He paid special attention to the cephalopoda of the Austrian Trias, and his publications include *Das Gebirge um Hallstatt* (1873–1876); *Die Dolomitrisse von Südtirol und Venetien* (1878–1880); *Grundlinien der Geologie von Bosnien-Herzegowina* (1880) with E. Tietze and A. Bittner; *Die Cephalopoden der mediterranen Triasprovinz* (1882); *Die cephalopoden der Hallstätter Kalke* (1873–1903); and *Beiträge zur Kenntniss der obertriadischen Cephalopodenfaunen des Himalaya* (1896). With Melchior Neumayr (1845–1890) he conducted the *Beiträge zur Paläontologie und Geologie Oesterreich-Ungarns*. In 1862, with Paul Grohmann and Dr Guido von Sommaruga, he founded the Austrian Alpine Club, and he also took part in establishing the German Alpine Club, which combined with the former in 1873.

MOKANNA (*al-Moqanna‘*, the Veiled), the name given to Ḥakīm, or ‘Aṭā, a man of unknown parentage, originally a fuller in Merv, who posed as an incarnation of Deity, and headed a revolt in Khorāsān against the caliph Mahdī. For about three years he sustained himself in the field against the troops of the caliph and for two years longer in his fortress of Sanam; then, reduced to straits in 779, he and his followers took poison and set fire to the fortress. Much is related to his magical arts, especially of a moonlike light visible for an enormous distance which he made to rise from a pit near Nakhshab. He is the hero of the first part of Moore's *Lalla Rookh*.

MOKHA (Mocha, properly Makha), a town in Arabia on the Red Sea coast in 13° 19′ N. and 43° 12′ E. Formerly the chief port for the Yemen coffee export, it has much diminished in importance. The coffee grown in the mountain districts of Haraz, Uden, and Ta‘iz is now shipped at Hodeda or Aden, though the article retains the trade name of "Mocha." The town lies in a small bay 40 m. N. of Perim at the southern entrance to the Red Sea. The anchorage is not good, and the port is only used by native vessels. Seen from the sea the town has rather an imposing appearance, but a near review shows that the houses though large and built of stone are mostly in ruins. The neighbouring country is an arid plain without fresh water, the town being supplied by an aqueduct from the village of Muza, situated 16 m. to the east. This is probably identical with the Muza of the Periplus, a great seat of the Red Sea trade in antiquity, which like Betel Fakih, Zubed and other old Tehama towns, formerly seaports, has long since been left by the receding sea. There is a Turkish kaimakam and a small garrison at Mokha, which is part of the civil district of Taiz in the vilayet of Yemen.

MOKSHANY, a town of Russia, in the government of Penza, 24 m. N.W. of the city of Penza. Pop. (1900), 10,710. The inhabitants are engaged in agriculture, or work in flour-mills, oilworks, tanneries and potash-works. Mokshany, which was built in 1535 as a fort to protect the country from the raids of the Tatars and the Kalmucks, is supposed to occupy the site of the Meshcheryak town of Murunza, mentioned as early as the 9th century.

MOLASSES, the syrup obtained from the drainings of raw sugar or from sugar during the process of refining. In American usage the word usually applies to both forms of the syrup, but in English usage the second form is more usually known as "treacle" (see SUGAR). The word, which in early forms appears as *melasses*, *molassos*, &c., is from the Port. *melaço*, or Fr. *mélasse*, cf. the Late Lat. *mellaceum*, syrup made from honey (*mel*). The geological term "molasse" must be distinguished; this word, applied to the soft greenish sandstone of the district between the Jura and the Alps, is French, meaning "soft," Lat. *mollis*.

MOLAY, JACQUES DE (d. 1314), last grand master of the Knights Templars, was born of a noble but impoverished family, at a village of the same name in the old province of Franche-Comté (mod. department of Haute-Saône), about the middle of the 13th century. The family property being the inheritance of an elder brother, Jacques was thrown upon his own resources. Having been brought up in the neighbourhood of a commandery of the Temple, he entered the order in 1265 at Beaune in the diocese of Autun. It is probable that he at once set out for the East to take part in the defence of the Holy Land against the Saracens. About 1295 he was elected grand master of the order. After the Templars had been driven out of Palestine by the Saracens, De Molay took refuge with the remnant of his followers in the island of Cyprus. Here, while attempting to get together a force to retrieve the disasters to the Christian arms, he received a summons (in 1306) from Pope Clement V. to repair to Paris. The pope's pretext for the summons was his desire to put an end to the quarrels between the Templars and the Knights of St John, and to concert plans for a new crusade; in reality he had entered into a secret agreement with the king of France for the suppression of the Templars. Molay left Cyprus with a retinue of 60 followers, and made a triumphal entry into Paris. On the 13th of October 1307 every Templar in France was arrested, and a prolonged examination of the members of the order was held. De Molay, probably under torture, confessed that some of the charges brought against the order were true. He was kept in prison for several years, and in 1314 he was brought up with three other dignitaries of the Temple before a commission of cardinals and others to hear the sentence (imprisonment for life) pronounced. Then, to the surprise of the commission, De Molay withdrew his confession. Immediately the king heard of it he gave orders that De Molay and another of the four, who had also recanted, should be burnt as lapsed heretics. The sentence was carried out on the 11th (or 19th) of March 1314. De Molay's ashes were gathered up by the people, and it is said that with his last breath he summoned the king and the pope to appear with him before the throne of God.

For the charges brought against the Templars and the famous process in connexion with them, see TEMPLARS; J. Michelet, *Procès des Templiers* (1841–1851) and Lavocat, *Procès des frères et de l'ordre du Temple d'après des pièces inédites publiées par M. Michelet* (1888); E. Besson, "Étude sur Jacques de Molay" in *Mémoires de la soc. d'émulation du Doubs* (Besançon, 1876); H. H. Milman, *Hist. of Latin Christianity*, bk. xii., chs. 1 and 2; H. Prutz, *Entwickelung und Untergang des Tempelherrenordens* (Berlin, 1888).

MOLD (formerly *Mould*, Welsh *Y Wyddgrug*, a conspicuous barrow, Lat. *Mons altus*, the translation of the Welsh name), a market town, contributory parliamentary borough of Flintshire, N. Wales; on the London & North-Western railway (Chester and Denbigh branch), 182 m. from London and 11 m. from Chester. Pop. of urban district (1901), 4263. The locality is populous owing to the collieries and lead-smelting works in the vicinity. At the north end of the town there is a height, Bailey Hill (perhaps from *ballia*, the architectural term applied to fortified castle courts). This hill, partly natural and partly artificial, was once the site of a Roman fortification, and in old records is known as Moaldes, Monhault, or Monthault (*de monte alto*). Mold Castle was probably built by Robert Monthault (*temp.* William Rufus), was taken and destroyed by Owen Gwynedd in 1144–1145, its site lost to the English and retaken by Llewelyn ap Iowerth in 1201, and by Gruffydd Llwyd in 1322. On this site, too, where there are now no remains of any fortress, were found, in 1849, some 15 skeletons, supposed to be of the 13th or 14th centuries. Maes Garmon (the battlefield of Germanus) is about a mile west of Mold. Here, as is supposed, the "Alleluia Victory" was gained over the Picts and Scots by Lupus and Germanus, bishop of Auxerre, according to some about A.D. 430, but others give A.D. 448, the date of the saint's death. A commemorative obelisk was erected on the Maes by N. Griffith of Rhual (1736). Over a mile south of Mold, on the right of the road to Nerquis, is the "Tower" (15th century, but perhaps restored in the 18th), where, in 1465 or 1475, the royal chieftain, Rheinallt ab Gruffyd ad Bleddyn, hanged Robert Byrne, mayor of Chester, and subsequently burned alive some 200 Chester folk who tried to arrest him. Many tumuli are visible round Mold.

Mold county gaol, bought in 1880 by Jesuits expelled from France, was by them named St Germanus's House. St Mary's church, a Gothic building, is mentioned as early as the time of Henry VII. Its important collieries and lead mines; fire-brick, tile, earthenware, mineral oil, tinplate and nail manufactures, tanneries, breweries and malt-houses, have made Mold the business centre of the county. About 4 m. distant is Cilcain village, of which the church has a carved oak roof, stolen from Basingwerk Abbey at the dissolution of the monasteries. Among the neighbouring Clwyd hills Moel Fammau and Moel Arthur are specially noticeable. On the summit of the former is George III.'s jubilee pyramid. The Ordovices and the Romans fortified Moel Arthur. The sites of seven posts established against Rome may be traced along the hills bounding Flintshire and Denbighshire.

MOLDAVIA, a former principality of south-eastern Europe, constituting, after its union with Wallachia on the 9th of November 1859, a part of Rumania (*q.v.*).

MOLDAVITE, an olive-green or dull greenish vitreous substance, named by A. Dufrénoy from Moldauthein in Bohemia, where it occurs. It is sometimes cut and polished as an ornamental stone under the name of pseudo-chrysolite. Its bottle-glass colour led to its being commonly called *Bouteillenstein*, and at one time it was regarded as an artificial product, but this view is opposed to the fact that no remains of glass-works are found in the neighbourhood of its occurrence: moreover pieces of the substance are widely distributed in Tertiary and early Pleistocene deposits in Bohemia and Moravia. For a long time it was generally believed to be a variety of obsidian, but its difficult fusibility and its chemical composition are rather against its volcanic origin. Dr F. E. Suess pointed out that the nodules or small masses of moldavite presented curious pittings and wrinkles on the surface, which could not be due to the action of water, but resembled the characteristic markings on many meteorites. Boldly attributing the material to a cosmic origin, he regarded moldavite as a special type of meteorite for which he proposed the name of tectite (Gr. τηκτός, melted). To this type are also referred the so-called obsidian bombs and buttons from Australia and Tasmania, known sometimes as australite, and called by R. H. Walcott obsidianites. Similar bodies have been found in Malaysia and have been termed billitonite, from the isle of Billiton where they occur in tin-bearing gravels. Usually they are flat, rounded or ellipsoidal bodies, sometimes surrounded by an equatorial girdle or rim, and often with a brilliant black superficial lustre, as though varnished. Moldavite has been reported also from Scania in Sweden.

See Franz E. Suess, *Jahrbuch der k.-k. geolog. Reichsanstalt* (Vienna), 1901, p. 193; E. Weinschenk, *Centralblatt f. Mineralogie* (Stuttgart), 1908, p. 737. (F. W. R.*)

MOLDE, a small seaside town of Norway, in Romsdal *amt* (county), 204 m. by sea N.N.E. of Bergen, in 62° 45′ N. (that of the Faroe Islands). It has little trade, but is the principal tourist centre on this part of the coast, and the steamers from Hull and Newcastle, the Norwegian ports, Hamburg, Antwerp, &c., call here. The town fronts the broad Molde Fjord, with its long low islands, and to the east and south a splendid panorama of jagged mountains is seen, reaching 6010 ft. in Store Troldtinder of the Romsdal group. Molde is the port for the tourist route through the Romsdal.

MOLÉ, LOUIS MATHIEU, Comte (1781–1855), French statesman, was born in Paris on the 24th of January 1781. His father, a president of the parlement of Paris, who came of the family of the famous president noticed below, was guillotined during the Terror, and Count Molé's early days were spent in Switzerland and in England with his mother, a relative of Lamoignon-Malesherbes. On his return to France he studied at the école centrale des travaux publics, and his social education was accomplished in the salon of Pauline de Beaumont, the friend of Châteaubriand and Joubert. A volume of *Essais de morale et de politique* introduced him to the notice of Napoleon, who attached him to the staff of the council of state. He became master of requests in 1806, and next year prefect of the Côte d'Or, councillor of state and director-general of bridges and roads in 1809, and count of the empire in the autumn of the same year. In November 1813 he became minister of justice. Although he resumed his functions as director-general during the Hundred Days, he excused himself from taking his seat in the council of state and was apparently not seriously compromised, for Louis XVIII. confirmed his appointment as director-general and made him a peer of France. Molé supported the policy of the duc de Richelieu, who in 1817 entrusted to him the direction of the ministry of marine, which he held until December 1818. From that time he belonged to the moderate opposition, and he accepted the result of the revolution of 1830 without enthusiasm. He was minister for foreign affairs in the first cabinet of Louis Philippe's reign, and was confronted with the task of reconciling the European powers to the change of government. The real direction of foreign affairs, however, lay less in his hands than in those of Talleyrand, who had gone to London as the ambassador of the new king. After a few months of office Molé retired, and it was not until 1836 that the fall of Thiers led to his becoming prime minister of a new government, in which he held the portfolio of foreign affairs. One of his first actions was the release of the ex-ministers of Charles X., and he had to deal with the disputes with Switzerland and with the Strassburg *coup* of Louis Napoleon. He withdrew the French garrison from Ancona, but pursued an active policy in Mexico and in Algeria. Personal and political differences rapidly arose between Molé and his chief colleague Guizot, and led to an open rupture in March 1837 in face of the general opposition to a grant to the duc de Nemours. After some attempts to secure a new combination Molé resonstructed his ministry in April, Guizot being excluded. The general election in the autumn gave him no fresh support in the Chamber of Deputies, while he had now to face a formidable coalition between Guizot, the Left Centre under Thiers, and politicians of the Dynastic Left and the Republican Left. Molé, supported by Louis Philippe, held his ground against the general hostility until the beginning of 1839, when, after acrid discussions on the address, the chamber was dissolved. The new house showed little change in the strength of parties, but Molé resigned on the 31st of March 1839. A year later he entered the Academy, and though he continued to speak frequently he took no important share in party politics. Louis Philippe sought his help in his vain efforts to form a ministry in February 1848. After the revolution he was deputy for the Gironde to the Constituent Assembly, and in 1849 to the Legislative Assembly, where he was one of the leaders of the Right until the *coup d'état* on the 2nd of December 1851 drove him from public life. He died at Champlâtreux (Seine-et-Oise) on the 23rd of November 1855.

See P. Thureau-Dangin, *Histoire de la monarchie de juillet* (1884–1892); and Robert Cougny, *Dict. des parlementaires français* (1891).

MOLÉ, MATHIEU (1584–1656), French statesman, son of Edouard Molé (d. 1614), who was for a time *procureur-général*, was educated at the university of Orleans. Admitted *conseiller* in 1606, he was *président aux requêtes* in 1610, *procureur-général* in succession to Nicolas de Bellièvre in 1614, and he took part in the assembly of the Notables summoned at Rouen in 1617. He fought in vain against the setting up of special tribunals, or commissions, to try prisoners charged with political offences, and for his persistence in the case of the brothers Louis and Michel de Marillac he was suspended in 1631, and ordered to appear at Fontainebleau in his own defence. Hitherto Molé's relations with Richelieu had been fairly good, but his inclination to the doctrines of Port Royal increased the differences between them, and it was not until after Richelieu's death that he was able to secure the release of his friend, the abbé de St Cyran. In 1641 he was appointed first president of the parlement, with the preliminary condition that he should not permit the general assembly of the chambers except by express order of the king. After Richelieu's death the pretensions of the parlement increased; the hereditary magistrature arrogated to itself the functions of the states-general, and in 1648 the parlement with the other sovereign courts (the *cour des aides*, the *grand conseil*, and the *cour des comptes*) met in one assembly and proposed for the royal sanction twenty-seven articles, which amounted in substance to a new constitution. In the long conflict between Anne of Austria and the parlement, Molé, without yielding the rights of the parlement, played a conciliatory part. In the popular tumult known as the day of the barricades (Aug. 26, 1648) he sought out Mazarin and the queen to demand the release of Pierre Broussel and his colleagues, whose seizure had been the original cause of the outbreak. Next day the parlement marched in procession to repeat Molé's demand. On their way back they were stopped by the crowd. "Turn, traitor," said one of the rebels to Molé, seizing him by the beard, "and unless you wish to be massacred, either bring back Broussel, or bring Mazarin as a hostage." Many magistrates fled; the remnant, headed by the intrepid Molé, returned to the Palais Royal, where Anne of Austria was induced to release the prisoners.

Molé's moderating counsels failed to prevent the outbreak of the first Fronde, but he negotiated the peace of Rueil in 1651, and averted a conflict between the partisans of Condé and of the Cardinal de Retz within the precincts of the Palais de Justice. He refused honours and rewards for himself or his family, but became keeper of the seals, in which capacity he was compelled to follow the court, and he therefore retired from the presidency of the parlement. He died on the 3rd of January 1656.

The *Mémoires* of Molé were edited for the Société de l'histoire de France (4 vols., 1855) by Aimé Champollion-Figeac, and his life was written by Baron A. G. P. de Barante in *Le Parlement et la Fronde* (1859). See also the memoirs of Omer Talon and of De Retz.

MOLE. (1) A small animal of the family *Talpidae* (see below). (2) A mark, or stain, and particularly a dark-coloured raised spot on the human skin. This word, O. Eng. *mál*, appears in such forms as *meil* or *mail*, in old forms of Teutonic languages, and in *mæl*, a sign; cf. Ger. *Denkmal*, a monument. It is probably cognate with Lat. *maculus*, spot. Its meaning of stain is seen in the corrupted form "iron-mould," properly "iron-mole," a stain produced on linen or cloth by rust or ink. (3) A large structure of rubble, stone or other material, used as a breakwater or pier (see Breakwater), or the space of water so enclosed, forming a harbour or anchorage. This word comes through the French from Lat. *moles*, a mass, large structure. The name of the "Mole of Hadrian" (*moles Hadriani*) is sometimes given to the mausoleum of that emperor, now the castle of St Angelo at Rome.

In zoology the name of *mole* (a contracted form of mouldwarp, *i.e.* mould-caster), is properly applicable to the common mole (*Talpa europaea*), a small, soft-furred, burrowing mammal, with minute eyes, and broad fossorial fore-feet, belonging to the order Insectivora and the family *Talpidae*. In a wider sense may be included under the same term the other Old World moles, the North American star-nosed and other moles, and the

African golden moles of the family *Chrysochloridae.* In a still wider sense the name is applied to the Asiatic zokors and the African strand-moles, belonging to the order Rodentia, as well as to the Australian marsupial mole.

The common mole is an animal about six inches in length, with a tail of one inch. The body is long and cylindrical, and, owing to the forward position of the front limbs, the head appears to rest between the shoulders; the muzzle is long and obtusely pointed, terminated by the nostrils, which are close together in front; the minute eye is almost hidden by the fur; the ear is without a conch, opening on a level with the surrounding skin; the fore-limbs are rather short and very muscular, terminating in broad, naked, shovel-shaped feet, the palms normally directed outwards, each with five sub-equal digits armed with strong flattened claws; the hind-feet, on the contrary, are long and narrow; and the toes are provided with slender claws. The body is densely covered with soft, erect, velvety fur—the hairs uniform in length and thickness, except on the muzzle and short tail, the former having some straight bristles on its sides, whilst the latter is clothed with longer and coarser hairs. The fur is generally black, with a more or less greyish tinge, or brownish-black, but various paler shades up to pure white have been observed.

The food of the mole consists chiefly of earthworms, in pursuit of which it forms its well-known underground excavations. The mole is one of the most voracious of mammals, and, if deprived of food, is said to succumb in from ten to twelve hours. Almost any kind of flesh is eagerly devoured by captive moles, which have been seen, as if maddened by hunger, to attack animals nearly as large as themselves, such as birds, lizards, frogs, and even snakes; toads, however, they will not touch, and no form of vegetable food attracts their notice. If two moles be confined together without food, the weaker is invariably devoured by the stronger. Moles take readily to the water—in this respect, as well as in external form, resembling their North American representatives. Bruce, writing in 1793, remarks that he saw a mole paddling towards a small island in the Loch of Clunie, 180 yds. from land, on which he noticed molehills.

The sexes come together about the second week in March, and the young—generally from four to six in number—which are brought forth in about six weeks, quickly attain their full size.

Much misconception has prevailed with regard to the structure of the mole's "fortress," *i.e.* the large breeding hillock, which is generally placed in bushes, or amid the roots of a tree; but a trustworthy account, by Mr L. E. Adams, will be found in the *Memoirs* of the Manchester Literary and Philosophical Society for 1903, vol. xlvii., pt. 2.

The geographical distribution of the mole exceeds that of all the other species of the genus taken together. It extends from England to Japan, and from the Dovre-Fjeld Mountains in Scandinavia and the Middle Dwina region in Russia to southern Europe and the southern slopes of the Himalaya, where it occurs at an elevation of 10,000 ft. In Great Britain it is found as far north as Caithness, but in Ireland and in the Western Isles of Scotland (except Mull) it is unknown. (See INSECTIVORA.) (G. E. D.; R. L.*)

MOLECULE (from mod. Lat. *molecula*, the diminutive of *moles*, a mass), in chemistry and physics, the minutest particle of matter capable of separate existence. The word appears to have been invented during the 17th century, and remained synonymous with "atom" (Gr. ἄτομος, from α-, privative, and τέμνειν, to cut) until the middle of the 19th century, when a differentiation was established. "Atom" has mainly a chemical import, being defined as the smallest particle of matter which can take part in a chemical reaction; a "molecule" is composed of atoms, generally two or more. For the detailed chemical significance of these terms, see CHEMISTRY; and for the atomic theory of the chemist (as distinguished from the atomic or molecular theory of the physicist) see ATOM; reference may also be made to the article MATTER.

The doctrine that matter can be divided into, or regarded as composed of, discrete particles (termed "atoms" by early writers, and "molecules" by modern ones) has at all times played an important part in metaphysics and natural science. The leading historical stages in the evolution of the modern conception of the molecular structure of matter are treated in the following passage from James Clerk Maxwell's article ATOM in the 9th edition of the *Ency. Brit.*

"Atom[1] (ἄτομος) is a body which cannot be cut in two. The atomic theory is a theory of the constitution of bodies which asserts that they are made up of atoms. The opposite theory is that of the homogeneity and continuity of bodies, and asserts, at least in the case of bodies having no apparent organization, such, for instance, as water, that as we can divide a drop of water into two parts which are each of them drops of water, so we have reason to believe that these smaller drops can be divided again, and the theory goes on to assert that there is nothing in the nature of things to hinder this process of division from being repeated over and over again, times without end. This is the doctrine of the infinite divisibility of bodies, and it is in direct contradiction with the theory of atoms.

"The atomists assert that after a certain number of such divisions the parts would be no longer divisible, because each of them would be an atom. The advocates of the continuity of matter assert that the smallest conceivable body has parts, and that whatever has parts may be divided.

"In ancient times Democritus was the founder of the atomic theory, while Anaxagoras propounded that of continuity, under the name of the doctrine of homoeomeria ('Ομοιομέρια), or of the similarity of the parts of a body to the whole. The arguments of the atomists, and their replies to the objections of Anaxagoras, are to be found in Lucretius.

"In modern times the study of nature has brought to light many properties of bodies which appear to depend on the magnitude and motions of their ultimate constituents, and the question of the existence of atoms has once more become conspicuous among scientific inquiries.

"We shall begin by stating the opposing doctrines of atoms and of continuity. The most ancient philosophers whose speculations are known to us seem to have discussed the ideas of number and of continuous magnitude, of space and time, of matter and motion, with a native power of thought which has probably never been surpassed. Their actual knowledge, however, and their scientific experience were necessarily limited, because in their days the records of human thought were only beginning to accumulate. It is probable that the first exact notions of quantity were founded on the consideration of number. It is by the help of numbers that concrete quantities are practically measured and calculated. Now, number is discontinuous. We pass from one number to the next *per saltum.* The magnitudes, on the other hand, which we meet with in geometry, are essentially continuous. The attempt to apply numerical methods to the comparison of geometrical quantities led to the doctrine of incommensurables, and to that of the infinite divisibility of space. Meanwhile, the same considerations had not been applied to time, so that in the days of Zeno of Elea time was still regarded as made up of a finite number of 'moments,' while space was confessed to be divisible without limit. This was the state of opinion when the celebrated arguments against the possibility of motion, of which that of Achilles and the tortoise is a specimen, were propounded by Zeno, and such, apparently, continued to be the state of opinion till Aristotle pointed out that time is divisible without limit, in precisely the same sense that space is. And the slowness of the development of scientific ideas may be estimated from the fact that Bayle does not see any force in this statement of Aristotle, but continues to admire the paradox of Zeno (Bayle's *Dictionary*, art. 'Zeno'). Thus the direction of true scientific progress was for many ages towards the recognition of the infinite divisibility of space and time.

"It was easy to attempt to apply similar arguments to matter. If matter is extended and fills space, the same mental operation by which we recognize the divisibility of space may be applied, in imagination at least, to the matter which occupies space. From this point of view the atomic doctrine might be regarded as a relic of the old numerical way of conceiving magnitude, and the opposite doctrine of the infinite divisibility of matter might appear for a time the most scientific. The atomists, on the other hand, asserted very strongly the distinction between matter and space. The atoms, they said, do not fill up the universe; there are void spaces between them. If it were not so, Lucretius tells us, there could be no motion, for the atom which gives way first must have some empty place to move into.

> 'Quapropter locus est intactus, inane, vacansque
> Quod si non esset, nulla ratione moveri
> Res possent; namque, officium quod corporis exstat,
> Officere atque obstare, id in omni tempore adesset
> Omnibus: haud igitur quicquam procedere posset,
> Principium quoniam cedendi nulla daret res.'
>
> *De rerum natura*, i. 335.

"The opposite school maintained then, as they have always done, that there is no vacuum—that every part of space is full of matter, that there is a universal plenum, and that all motion is like that of a fish in the water, which yields in front of the fish because the fish leaves room for it behind.

---

[1] It will be noted that Clerk Maxwell's "atom" and "atomic theory" have the significance which we now attach to "molecule" and "molecular theory."

> 'Cedere squamigeris latices nitentibus aiunt
> Et liquidas aperire vias, quia post loca pisces
> Linquant, quo possint cedentes confluere undae.'
>
> Ibid. i. 373.

"In modern times Descartes held that, as it is of the essence of matter to be extended in length, breadth and thickness, so it is of the essence of extension to be occupied by matter, for extension cannot be an extension of nothing.

"'Ac proinde si quaeratur quid fiet, si Deus auferat omne corpus quod in aliquo vase continetur, et nullum aliud in ablati locum venire permittat? respondendum est, vasis latera sibi invicem hoc ipso fore contigua. Cum enim inter duo corpora nihil interjacet, necesse est ut se mutuo tangant, ac manifeste repugnat ut distent, sive ut inter ipsa sit distantia, et tamen ut ista distantia sit nihil; quia omnis distantia est modus extensionis, et ideo sine substantia extensa esse non potest.'—*Principia*, ii. 18.

"This identification of extension with substance runs through the whole of Descartes's works; and it forms one of the ultimate foundations of the system of Spinoza. Descartes, consistently with this doctrine, denies the existence of atoms as parts of matter, which by their own nature are indivisible. He seems to admit, however, that the Deity might make certain particles of matter indivisible in this sense, that no creature should be able to divide them. These particles, however, would be still divisible by their own nature, because the Deity cannot diminish his own power, and therefore must retain his power of dividing them. Leibniz, on the other hand, regarded his monad as the ultimate element of everything.

"There are thus two modes of thinking about the constitution of bodies, which have had their adherents both in ancient and in modern times. They correspond to the two methods of regarding quantity—the arithmetical and the geometrical. To the atomist the true method of estimating the quantity of matter in a body is to count the atoms of it. The void spaces between the atoms count for nothing. To those who identify matter with extension, the volume of space occupied by a body is the only measure of the quantity of matter in it.

"Of the different forms of the atomic theory that of R. J. Boscovich may be taken as an example of the purest monadism. According to Boscovich matter is made up of atoms. Each atom is an indivisible point, having position in space, capable of motion in a continuous path, and possessing a certain mass, whereby a certain amount of force is required to produce a given change of motion. Besides this the atom is endowed with potential force, that is to say, that any two atoms attract or repel each other with a force depending on their distance apart. The law of this force, for all distances greater than say the thousandth of an inch, is an attraction varying as the inverse square of the distance. For smaller distances the force is an attraction for one distance and a repulsion for another, according to some law not yet discovered. Boscovich himself, in order to obviate the possibility of two atoms ever being in the same place, asserts that the ultimate force is a repulsion which increases without limit as the distance diminishes without limit, so that two atoms can never coincide. But this seems an unwarrantable concession to the vulgar opinion that two bodies cannot co-exist in the same place. This opinion is deduced from our experience of the behaviour of bodies of sensible size, but we have no experimental evidence that two atoms may not sometimes coincide. For instance, if oxygen and hydrogen combine to form water, we have no experimental evidence that the molecule of oxygen is not in the very same place with the two molecules of hydrogen. Many persons cannot get rid of the opinion that all matter is extended in length, breadth and depth. This is a prejudice of the same kind with the last, arising from our experience of bodies consisting of immense multitudes of atoms. The system of atoms, according to Boscovich, occupies a certain region of space in virtue of the forces acting between the component atoms of the system and any other atoms when brought near them. No other system of atoms can occupy the same region of space at the same time, because before it could do so the mutual action of the atoms would have caused a repulsion between the two systems insuperable by any force which we can command. Thus, a number of soldiers with firearms may occupy an extensive region to the exclusion of the enemy's armies, though the space filled by their bodies is but small. In this way Boscovich explained the apparent extension of bodies consisting of atoms, each of which is devoid of extension. According to Boscovich's theory, all action between bodies is action at a distance. There is no such thing in nature as actual contact between two bodies. When two bodies are said in ordinary language to be in contact, all that is meant is that they are so near together that the repulsion between the nearest pairs of atoms belonging to the two bodies is very great.

"Thus, in Boscovich's theory, the atom has continuity of existence in time and space. At any instant of time it is at some point of space, and it is never in more than one place at a time. It passes from one place to another along a continuous path. It has a definite mass which cannot be increased or diminished. Atoms are endowed with the power of acting on one another by attraction or repulsion, the amount of the force depending on the distance between them. On the other hand, the atom itself has no parts or dimensions. In its geometrical aspect it is a mere geometrical point. It has no extension in space. It has not the so-called property, of Impenetrability, for two atoms may exist in the same place. This we may regard as one extreme of the various opinions about the constitution of bodies.

"The opposite extreme, that of Anaxagoras—the theory that bodies apparently homogeneous and continuous are so in reality—is, in its extreme form, a theory incapable of development. To explain the properties of any substance by this theory is impossible. We can only admit the observed properties of such substance as ultimate facts. There is a certain stage, however, of scientific progress in which a method corresponding to this theory is of service. In hydrostatics, for instance, we define a fluid by means of one of its known properties, and from this definition we make the system of deductions which constitutes the science of hydrostatics. In this way the science of hydrostatics may be built upon an experimental basis, without any consideration of the constitution of a fluid as to whether it is molecular or continuous. In like manner, after the French mathematicians had attempted, with more or less ingenuity, to construct a theory of elastic solids from the hypothesis that they consist of atoms in equilibrium under the action of their mutual forces, Stokes and others showed that all the results of this hypothesis, so far at least as they agreed with facts, might be deduced from the postulate that elastic bodies exist, and from the hypothesis that the smallest portions into which we can divide them are sensibly homogeneous. In this way the principle of continuity, which is the basis of the method of Fluxions and the whole of modern mathematics, may be applied to the analysis of problems connected with material bodies by assuming them, for the purpose of this analysis, to be homogeneous. All that is required to make the results applicable to the real case is that the smallest portions of the substance of which we take any notice shall be sensibly of the same kind. Thus, if a railway contractor has to make a tunnel through a hill of gravel, and if one cubic yard of the gravel is so like another cubic yard that for the purposes of the contract they may be taken as equivalent, then, in estimating the work required to remove the gravel from the tunnel, he may, without fear of error, make his calculations as if the gravel were a continuous substance. But if a worm has to make his way through the gravel, it makes the greatest possible difference to him whether he tries to push right against a piece of gravel, or directs his course through one of the intervals between the pieces; to him, therefore, the gravel is by no means a homogeneous and continuous substance.

"In the same way, a theory that some particular substance, say water, is homogeneous and continuous may be a good working theory up to a certain point, but may fail when we come to deal with quantities so minute or so attenuated that their heterogeneity of structure comes into prominence. Whether this heterogeneity of structure is or is not consistent with homogeneity and continuity of substance is another question.

"The extreme form of the doctrine of continuity is that stated by Descartes, who maintains that the whole universe is equally full of matter, and that this matter is all of one kind, having no essential property besides that of extension. All the properties which we perceive in matter he reduces to its parts being movable among one another, and so capable of all the varieties which we can perceive to follow from the motion of its parts (*Principia*, ii. 23). Descartes's own attempts to deduce the different qualities and actions of bodies in this way are not of much value. More than a century was required to invent methods of investigating the conditions of the motion of systems of bodies such as Descartes imagined. But the hydrodynamical discovery of Helmholtz that a vortex in a perfect liquid possesses certain permanent characteristics has been applied by Sir W. Thomson (Lord Kelvin) to form a theory of vortex atoms in a homogeneous, incompressible and frictionless liquid."

THE MOLECULAR STRUCTURE OF MATTER

An enormous mass of experimental evidence now shows quite conclusively that matter cannot be regarded as having a continuous structure, but that it is ultimately composed of discrete parts. The smallest unit of matter with which physical phenomena are concerned is the *molecule*. When chemical phenomena occur the molecule may be divided into *atoms*, and these atoms, in the presence of electrical phenomena, may themselves be further divided into *electrons* or *corpuscles*. It ought accordingly to be possible to explain all the non-electrical and non-chemical properties of matter by treating matter as an aggregation of molecules. In point of fact it is found that the properties which are most easily explained are those connected with the gaseous state; the explanation of these properties in terms of the molecular structure of matter is the aim of the "Kinetic Theory of Gases." The results of this theory have placed the molecular conception of matter in an indisputable position, but even without this theory there is such an accumulation of electrical and optical evidence in favour of the molecular conception of matter that the tenability of this conception could not be regarded as open to question.

The Scale of Molecular Structure.—Apart from speculation, the first definite evidence for the molecular structure of matter occurs when it is found that certain physical phenomena change their whole nature as soon as we deal with matter of which the linear dimensions are less than a certain amount. As a single instance of this may be mentioned some experiments of Lord Rayleigh (*Proc. Roy. Soc.*, 1890, 47, p. 364), who found that a film of olive oil spread over the surface of water produced a perceptible effect on small floating pieces of camphor, at places at which the thickness of the film was $10{\cdot}6\times10^{-8}$ cms., but produced no perceptible effect at all at places where the thickness of the film was $8{\cdot}1\times10^{-8}$ cms. Thus a certain phenomenon, of the nature of capillary action, is seen to depend for its existence on the linear dimensions of the film of oil; the physical properties of a film of thickness $10{\cdot}6\times10^{-8}$ cms. are found to be in some way qualitatively different from those of a film of thickness $8{\cdot}1\times10^{-8}$ cms. Here is proof that the film of oil is not a continuous homogeneous structure, and we are led to suspect that the scale on which the structure is formed has a unit of length comparable with 8×10^{-8} cms. The probability of this conjecture is strengthened when it is discovered that in all phenomena of this type the critical length connected with the stage at which the phenomenon changes its nature is of the order of magnitude of 10^{-8} cms.

Lord Rayleigh (*Phil. Mag.* 1890 [5], 30, p. 474) has pointed out that the earliest known attempt to estimate the size of molecules, made by Thomas Young in 1805, was based upon the consideration of phenomena of the kind just mentioned. Discussing the theory of capillary attractions, Young[1] found that at a rough estimate "the extent of the cohesive force must be limited to about the 250-millionth of an inch" ($=10^{-8}$ cms.), and then argues that "within similar limits of uncertainty we may obtain something like a conjectural estimate of the mutual distance of the particles of vapours, and even of the actual magnitude of the elementary atoms of liquids. . . . It appears tolerably safe to conclude that, whatever errors may have affected the determination, the diameter or distance of the particles of water is between the two thousand and the ten thousand millionth of an inch" (=between $\cdot125\times10^{-8}$ and $\cdot025\times10^{-8}$ cms.).

The best estimates which we now possess of the sizes of molecules are provided by calculations based upon the kinetic theory of gases. In the following table are given the values of the diameters of the molecules of six substances with which it is easy to experiment in the gaseous state, these values being calculated in different ways from formulae supplied by the kinetic theory.

Gas.	Diameter calculated by the kinetic theory of gases.				
	From deviations from Boyle's law.	From coefficient of viscosity.	From coefficient of conduction of heat.	From coefficient of diffusion.	Mean value.
Hydrogen	$2{\cdot}05\times10^{-8}$	$2{\cdot}05\times10^{-8}$	$1{\cdot}99\times10^{-8}$	$2{\cdot}02\times10^{-8}$	$2{\cdot}03\times10^{-8}$
Carbon monoxide	—	$2{\cdot}90\times10^{-8}$	$2{\cdot}74\times10^{-8}$	$2{\cdot}92\times10^{-8}$	$2{\cdot}85\times10^{-8}$
Nitrogen .	$3{\cdot}12\times10^{-8}$	$2{\cdot}90\times10^{-8}$	$2{\cdot}74\times10^{-8}$	—	$2{\cdot}92\times10^{-8}$
Air . .	$2{\cdot}90\times10^{-8}$	$2{\cdot}86\times10^{-8}$	$2{\cdot}72\times10^{-8}$	—	$2{\cdot}83\times10^{-8}$
Oxygen .	—	$2{\cdot}81\times10^{-8}$	$2{\cdot}58\times10^{-8}$	$2{\cdot}70\times10^{-8}$	$2{\cdot}70\times10^{-8}$
Carbon dioxide .	$3{\cdot}00\times10^{-8}$	$3{\cdot}47\times10^{-8}$	$3{\cdot}58\times10^{-8}$	$3{\cdot}28\times10^{-8}$	$3{\cdot}33\times10^{-8}$

The agreement of the values obtained for the same quantity by different methods provides valuable confirmation of the truth of the molecular theory and of the validity of the methods of the kinetic theory of gases. That the results do not agree even better need not cause surprise when it is stated that the quantities are calculated on the hypothesis that the molecules are spherical in shape. This hypothesis is introduced for the sake of simplicity, but is known to be unjustifiable in fact. What is given by the formulae is accordingly the mean radius of an irregularly shaped solid (or, more probably, of the region in which the field of force surrounding such a solid is above a certain intensity), and the mean has to be taken in different ways in the different phenomena. This and the difficulty of obtaining accurate experimental results fully account for the differences *inter se* in the values of the quantities calculated.

Heat a Manifestation of Molecular Motion.—An essential feature of the modern view of the structure of matter is that the molecules are supposed to be in rapid motion relatively to one another. We are led to this conception by a number of experimental results, some of which will be mentioned later. We are compelled also to suppose that the motion assumes different forms in different substances. Roughly speaking, it is found that there are three main types of molecular motion corresponding to the three states of matter—solid, liquid and gaseous. That the distances traversed by the molecules of a solid are very small in extent is shown by innumerable facts of everyday observation, as for instance, the fact that the surface of a finely-carved metal (such as a plate used for steel engraving) will retain its exact shape for centuries, or again, the fact that when a metal body is coated with gold-leaf the molecules of the gold remain on its surface indefinitely: if they moved through any but the smallest distances they would soon become mixed with the molecules of the baser metal and diffused through its interior. Thus the molecules of a solid must make only small excursions about their mean positions. In a gas the state of things is very different; an odour is known to spread rapidly through great distances, even in the stillest air, and a gaseous poison or corrosive will attack not only those objects which are in contact with its source but also all those which can be reached by the motion of its molecules.

As a preliminary to examining further into the nature of molecular motion and the differences of character of this motion, let us try to picture the state of things which would exist in a mass of solid matter in which all the molecules are imagined to be at rest relatively to one another. The fact that a solid body in its natural state is capable both of compression and of dilatation indicates that the molecules of the body must not be supposed to be fixed rigidly in position relative to one another; the further fact that a motion of either compression or of dilatation is opposed by forces which are brought into play in the interior of the solid suggests that the position of rest is one in which the molecules are in stable equilibrium under their mutual forces. Such a mass of imaginary matter as we are now considering may be compared to a collection of heavy particles held in position relatively to one another by a system of light spiral springs, one spring being supposed to connect each pair of adjacent particles. Let two such masses of matter be suspended by strings from the same point, and then let one mass be drawn aside, pendulum-wise, and allowed to impinge on the other. After impact the two masses will rebound, and the process may be repeated any number of times, but ultimately the two masses will be found again hanging in contact side by side. At the first impact each layer of surface molecules which takes the shock of the impact will be thrust back upon the layer behind it: this layer will in this way be set into motion and so influence the layer still further behind; and so on indefinitely. The impact will accordingly result in all the molecules being set into motion, and by the time that the masses have ceased impinging on one another the molecules of which they are composed will be performing oscillations about their positions of equilibrium. The kinetic energy with which the moving mass originally impinged on that at rest is now represented by the energy, kinetic and potential, of the small motions of the individual molecules. It is known, however, that when two bodies impinge, the kinetic energy which appears to be lost from the mass-motion of the bodies is in reality transformed into heat-energy. Thus the molecular theory of matter, as we have now pictured it, leads us to identify heat-energy in a body with the energy of motion of the molecules of the body relatively to one another. A body in which all the molecules were at rest relatively to one another would be a body devoid of heat. This conception of the nature of heat leads at once to an absolute zero of temperature—a temperature of no heat-motion—which is identical, as will be seen later, with that reached in other ways, namely, about − 273° C.

---

[1] "On the Cohesions of Fluids," *Phil. Trans.* (1805); Young's *Coll. Works*, i. 461.

The point of view which has now been gained enables us to interpret most of the thermal properties of solids in terms of molecular theory. Suppose for instance that two bodies, both devoid of heat, are placed in contact with one another, and that the surface of the one is then rubbed over that of the other. The molecules of the two surface-layers will exert forces upon one another, so that, when the rubbing takes place, each layer will set the molecules of the other into motion, and the energy of rubbing will be used in establishing this heat-motion. In this we see the explanation of the phenomenon of the generation of heat by friction. At first the heat-motion will be confined to molecules near the rubbing surfaces of the two bodies, but, as already explained, these will in time set the interior molecules into motion, so that ultimately the heat-motion will become spread throughout the whole mass. Here we have an instance of the conduction of heat.[1] When the molecules are oscillating about their equilibrium positions, there is no reason why their mean distance apart should be the same as when they are at rest. This leads to an interpretation of the fact that a change of dimensions usually attends a change in the temperature of a substance. Suppose for instance that two molecules, when at rest in equilibrium, are at a distance a apart. It is very possible that the repulsive force they exert when at a distance $a-\epsilon$ may be greater than the attractive force they exert when at a distance $a+\epsilon$. If so, it is clear that their mean distance apart, averaged through a sufficiently long interval of their motion, will be greater than a. A body made up of molecules of this kind will expand on heating.

As the temperature of a body increases the average energy of the molecules will increase, and therefore the range of their excursions from their positions of equilibrium will increase also. At a certain temperature a stage will be reached in which it is a frequent occurrence for a molecule to wander so far from its position of equilibrium, that it does not return but falls into a new position of equilibrium and oscillates about this. When the body is in this state the relative positions of the molecules are not permanently fixed, so that the body is no longer of unalterable shape: it has assumed a plastic or molten condition. The substance attains to a perfectly liquid state as soon as the energy of motion of the molecules is such that there is a constant rearrangement of position among them.

A molecule escaping from its original position in a body will usually fall into a new position in which it will be held in equilibrium by the forces from a new set of neighbouring molecules. But if the wandering molecule was originally close to the surface of the body, and if it also happens to start off in the right direction, it may escape from the body altogether and describe a free path in space until it is checked by meeting a second wandering molecule or other obstacle. The body is continually losing mass by the loss of individual molecules in this way, and this explains the process of evaporation. Moreover, the molecules which escape are, on the whole, those with the greatest energy. The average energy of the molecules of the liquid is accordingly lowered by evaporation. In this we see the explanation of the fall of temperature which accompanies evaporation.

When a liquid undergoing evaporation is contained in a closed vessel, a molecule which has left the liquid will, after a certain number of collisions with other free molecules and with the sides of the vessel, fall back again into the liquid. Thus the process of evaporation is necessarily accompanied by a process of recondensation. When a stage is reached such that the number of molecules lost to the liquid by evaporation is exactly equal to that regained by condensation, we have a liquid in equilibrium with its own vapour. If the whole liquid becomes vaporized before this stage is attained, a state will exist in which the vessel is occupied solely by free molecules, describing paths which are disturbed only by encounters with other free molecules or the sides of the vessel. This is the conception which the molecular theory compels us to form of the gaseous state.

At normal temperature and pressure the density of a substance in the gaseous state is of the order of one-thousandth of the density of the same substance in the solid or liquid state. It follows that the average distance apart of the molecules in the gaseous state is roughly ten times as great as in the solid or liquid state, and hence that in the gaseous state the molecules are at distances apart which are large compared with their linear dimensions. (If the molecules of air at normal temperature and pressure were arranged in cubical order, the edge of each cube would be about $2{\cdot}9\times10^{-7}$ cms.; the average diameter of a molecule in air is $2{\cdot}8\times10^{-8}$ cms.) Further and very important evidence as to the nature of the gaseous state of matter is provided by the experiments of Joule and Kelvin. These experiments showed that the change in the temperature of a gas, consequent on its being allowed to stream out into a vacuum, is in general very slight. In terms of the molecular theory this indicates that the total energy of the gas is the sum of the separate energies of its different molecules: the potential energy arising from intermolecular forces between pairs of molecules may be treated as negligible when the matter is in the gaseous state.

These two simplifying facts bring the properties of the gaseous state of matter within the range of mathematical treatment. The kinetic theory of gases attempts to give a mathematical account, in terms of the molecular structure of matter, of all the non-chemical and non-electrical properties of gases. The remainder of this article is devoted to a brief statement of the methods and results of the kinetic theory. No attempt will be made to follow the historic order of development, but the present theory will be set out in its most logical form and order.

The Kinetic Theory of Gases.

A number of molecules moving in obedience to dynamical laws will pass through a series of configurations which can be theoretically determined as soon as the structure of each molecule and the initial position and velocity of every part of it are known. The determination of the series of configurations developing out of given initial conditions is not, however, the problem of the kinetic theory: the object of this theory is to explain the general properties of all gases in terms only of their molecular structure. We are therefore called upon, not to trace the series of configurations of any single gas, starting from definite initial conditions, but to search for features and properties common to all series of configurations, independently of the particular initial conditions from which the gas may have started.

Dynamical Basis.

We begin with a general dynamical theorem, whose special application, when the dynamical system is identified with a gas, will appear later. Let $q_1, q_2, \ldots q_n$ be the generalized co-ordinates of any dynamical system, and let $p_1, p_2, \ldots p_n$ be the corresponding momenta. If the system is supposed to obey the conservation of energy and to move solely under its own internal forces, the changes in the co-ordinates and momenta can be found from the Hamiltonian equations

$$\dot{q}_r=\frac{\partial E}{\partial p_r},\ \dot{p}_r=-\frac{\partial E}{\partial q_r}, \qquad (1)$$

where $\dot{q}_r$ denotes dq_r/dt, &c., and E is the total energy expressed as a function of $p_1, q_1, \ldots p_n, q_n$. When the initial values of $p_1, q_1 \ldots p_n, q_n$, are given, the motion can be traced completely from these equations.

Let us suppose that an infinite number of exactly similar systems start simultaneously from all possible values of $p_1, q_1, \ldots p_n, q_n$, each moving solely under its own internal forces, and therefore in accordance with equations (1). Let us confine our attention to those systems for which the initial values of $p_1, q_1, \dots p_n, q_n$ lie within a range such that

---

[1] Other processes also help in the conduction of heat, especially in substances which are conductors of electricity.

$$\begin{array}{l} p_1 \text{ is between } p_1 \text{ and } p_1+dp_1 \\ q_1 \;\;\text{,,}\;\;\;\text{,,}\;\;\; q_1 \;\;\text{,,}\;\; q_1+dq_1, \text{ and so on.} \end{array}$$

Let the product $dp_1\,dq_1 \dots dp_n\,dq_n$ be spoken of as the "extension" of this range of values.

After a time dt the value of p_1 will have increased to p_1+p_1dt, where p_1 is given by equations (1), and there will be similar changes in $q_1, p_2, q_2, \dots q_n$. Thus after a time dt the values of the co-ordinates and momenta of the small group of systems under consideration will lie within a range such that

$$\begin{array}{l} p_1 \text{ is between } p_1+\dot{p}_1dt \text{ and } p_1+dp_1+\left(\dot{p}_1+\dfrac{\partial\dot{p}_1}{\partial p_1}dp_1\right)dt \\ q_1 \;\;\text{,,}\;\;\;\text{,,}\;\;\; q_1+\dot{q}_1dt \;\;\text{,,}\;\; q_1+dq_1+\left(\dot{q}_1+\dfrac{\partial\dot{q}_1}{\partial q_1}dq_1\right)dt, \end{array}$$

and so on. Thus the extension of the range after the interval dt is

$$dp_1\left(1+\frac{\partial\dot{p}_1}{\partial p_1}dt\right)dq_1\left(1+\frac{\partial\dot{q}_1}{\partial q_1}dt\right)\dots$$

or, expanding as far as first powers of dt,

$$dp_1dq_1 \dots dp_ndq_n\left\{1+\Sigma_1^n\left(\frac{\partial\dot{p}_1}{\partial p_1}+\frac{\partial\dot{q}_1}{\partial q_1}\right)dt\right\}.$$

From equations (1), we find that

$$\frac{\partial\dot{p}_1}{\partial p_1}+\frac{\partial\dot{q}_1}{\partial q_1}=0,$$

so that the extension of the new range is seen to be $dp_1dq_1 \dots dp_ndq_n$, and therefore equal to the initial extension. Since the values of the co-ordinates and momenta at any instant during the motion may be treated as "initial" values, it is clear that the "extension" of the range must remain constant throughout the whole motion.

This result at once disposes of the possibility of all the systems acquiring any common characteristic in the course of their motion through a tendency for their co-ordinates or momenta to concentrate about any particular set, or series of sets, of values. But the result goes further than this. Let us imagine that the systems had the initial values of their co-ordinates and momenta so arranged that the number of systems for which the co-ordinates and momenta were within a given range was proportional simply to the extension of the range. Then the result proves that the values of the co-ordinates and momenta remain distributed in this way throughout the whole motion of the systems. Thus, if there is any characteristic which is common to all the systems after the motion has been in progress for any interval of time, this same characteristic must equally have been common to all the systems initially. It must, in fact, be a characteristic of all possible states of the systems.

It is accordingly clear that there can be no property common to all systems, but it can be shown that when the system contains a gas (or any other aggregation of similar molecules) as part of it there are properties which are common to all possible states, except for a number which form an insignificant fraction of the whole. These properties are found to account for the physical properties of gases.

Let the whole energy E of the system be supposed equal to E_1+E_2, where E_2 is of the form

$$\begin{aligned} E_2 = {} & \tfrac{1}{2}\sum_s(mu^2+mv^2+mw^2+a_1\theta_1^2+a_2\theta_2^2+ \dots +a_n\theta_n^2) \\ & +\tfrac{1}{2}\sum_{s'}(m'u'^2+m'v'^2+m'w'^2+\beta_1\phi_1^2+\beta_2\phi_2^2+ \dots +\beta_{n'}\phi_{n'}^2) \qquad (2) \end{aligned}$$

where $\theta_1, \theta_2, \dots \theta_n$ and similarly $\phi_1, \phi_2, \dots \phi_{n'}$ are any momenta or functions of the co-ordinates and momenta or co-ordinates alone which are subject only to the condition that they do not enter into the coefficients a_1, a_2, &c.

In this expression the first line may be supposed to represent the energy (or part of the energy) of s similar molecules of a kind which we shall call the first kind, the terms $\frac{1}{2}(mu^2+mv^2+mw^2)$ being the kinetic energy of translation, and the remaining terms arising from energy of rotation or of internal motion, or from the energy, kinetic and potential, of small vibrations. The second line in E_2 will represent the energy (or part of the energy) of s' similar molecules of the second kind, and so on. It is not at present necessary to suppose that the molecules are those of substances in the gaseous state. Considering only those states of the system which have a given value of E_2, it can be proved, as a theorem in pure mathematics,[1] that when $s, s', \dots$ are very large, then, for all states except an infinitesimal fraction of the whole number, the values of u, v, w lie within ranges such that

(i) the values of u (and similarly of v, w) are distributed among the s molecules of the first kind according to the law of trial and error; and similarly of course for the molecules of other kinds:

(ii)
$$\frac{\sum_s\frac{1}{2}mu^2}{s}=\frac{\sum_s\frac{1}{2}mv^2}{s}=\frac{\sum_s\frac{1}{2}mw^2}{s}=\frac{\sum_s\frac{1}{2}a_1\theta_1^2}{s}=\dots$$
$$=\frac{\sum_{s'}\frac{1}{2}m'u'^2}{s'}=\dots=\frac{\sum_{s'}\frac{1}{2}\beta\phi_1^2}{s'}=\dots \qquad (3)$$

The Normal State.

A state of the system in which these two properties are true will be called a "normal state"; other states will be spoken of as "abnormal." Let all possible states of the system be divided into small ranges of equal extension, and of these let a number P correspond to normal, and a number p to abnormal, states. What is proved is that, as $s, s', \dots$ become very great, the ratio P/p becomes infinite. Considering only systems starting in the p abnormal ranges, it is clear, from the fact that the extensions of the ranges do not change with the motion, that after a sufficient time most of these systems must have passed into the P normal ranges. Speaking loosely, we may say that there is a probability $P/(P+p)$, amounting to certainty in the limit, that one of these systems, selected at random, will be in the normal state after a sufficient time has elapsed. Again, considering the systems which start from the P normal ranges, we see that there is a probability $p/(P+p)$ which vanishes in the limit, that a system selected at random from these will be in an abnormal state after a sufficient time. Thus, subject to a probability of error which is infinitesimal in the limit, we may state as general laws that—

A system starting from an abnormal state tends to assume the normal state; while

A system starting from the normal state will remain in the normal state.

It will now be found that the various properties of gases follow from the supposition that the gas is in the normal state.

Law of Distribution of Velocities.

If each of the fractions (3) is put equal to $1/4h$, it is readily found, from the first property of the normal state, that, of the s molecules of the first kind, a number

$$s\sqrt{(h^3m^3/\pi^3)}e^{-hm(u^2+v^2+w^2)}dudvdw \qquad (4)$$

have velocities of which the components lie between u and $u+du$, v and $v+dv$, w and $w+dw$, while the corresponding number of molecules of the second kind is, similarly,

$$s'\sqrt{(h^3m'^3/\pi^3)}e^{-hm'(u^2+v^2+w^2)}dudvdw. \qquad (5)$$

If c is the resultant velocity of a molecule, so that $c^2=u^2+v^2+w^2$, it is readily found from formula (4) that the number of molecules of the first kind of which the resultant velocity lies between c and $c+dc$ is

$$4\pi s\sqrt{(h^3m^3/\pi^3)}e^{-hmc^2}c^2dc. \qquad (6)$$

These formulae express the "law of distribution of velocities" in the normal state: the law is often called *Maxwell's Law of Distribution.*

Equipartition of Energy.

If $\frac{1}{2}\overline{mu^2}$ denote the mean value of $\frac{1}{2}mu^2$ averaged over the s molecules of the first kind, equations (3) may be written in the form

$$\tfrac{1}{2}\overline{mu^2}=\tfrac{1}{2}\overline{mv^2}=\tfrac{1}{2}\overline{mw^2}=\tfrac{1}{2}\overline{a_1\theta_1^2}=\dots=1/4h, \qquad (7)$$

showing that the mean energy represented by each term in E_2 (formula 2) is the same. These equations express the "law of equipartition of energy," commonly spoken of as the *Maxwell-Boltzmann Law.*

Temperature.

The law of equipartition shows that the various mean energies of different kinds are all equal, each being measured by the quantity $1/4h$. We have already seen that the mean energy increases with the temperature: it will now be supposed that the mean energy is exactly proportional to the temperature. The complete justification for this supposition will appear later: a partial justification is obtained as soon as it is seen how many physical laws can be explained by it. We accordingly put $1/2h=RT$, where T denotes the temperature on the absolute scale, and then have equations (7) in the form

$$\overline{mu^2}=\overline{mv^2}=\dots=RT. \qquad (8)$$

When a system is composed of a mixture of different kinds of molecules, the fact that h is the same for each constituent [cf. formulae (5) and (6)] shows that in the normal state the different substances are all at the same temperature. For instance, if the system is composed of a gas and a solid boundary, some of the terms in expression (2) may be supposed to represent the kinetic energy of the molecules of the boundary, so that equations (7) show that in the normal state the gas has the same temperature as the boundary. The process of equalization of temperature is now seen to be a special form of the process of motion towards the normal state: the general laws which have been stated above in connexion with the normal state are seen to include as special cases the following laws:—

Matter originally at non-uniform temperature tends to assume a uniform temperature; while

Matter at uniform temperature will remain at uniform temperature.

It will at once be apparent that the kinetic theory of matter enables us to place the second law of thermodynamics upon a purely dynamical basis. So far it has not been necessary to suppose the matter to be in the gaseous state. We now pass to the consideration of laws and properties which are peculiar to the gaseous state.

Pressure of a Gas.

A simple approximate calculation of the pressure exerted by a gas on its containing vessel can be made by supposing that the molecules are so small in comparison with their distances apart that they may be treated as of infinitesimal size. Let a mixture of gases contain per unit volume ν molecules of the first kind, ν' of the second kind, and so on. Let us fix our attention on a small area dS of the boundary of the vessel, and let co-ordinate axes be taken such that the origin is in dS, and the axis of x is the normal at the origin into the gas. The number of molecules of the first kind of gas, whose components of velocity lie within the ranges between u and $u+du$, v and $v+dv$, w and $w+dw$, will, by formula (5), be

---

[1] See Jeans, *Dynamical Theory of Gases* (1904), ch. v.

$$\nu\sqrt{(h^3m^3/\pi^3)}e^{-hm(u^2+v^2+w^2)}dudvdw \qquad (9)$$

per unit volume. Construct a small cylinder inside the gas, having dS as base and edges such that the projections of each on the co-ordinate axes are udt, vdt, wdt. Each of the molecules enumerated in expression (9) will move parallel to the edge of this cylinder, and each will describe a length equal to its edge in time dt. Thus each of these molecules which is initially inside the cylinder, will impinge on the area dS within an interval dt. The cylinder is of volume $u\,dt\,dS$, so that the product of this and expression (9) must give the number of impacts between the area dS and molecules of the kind under consideration within the interval dt. Each impinging molecule exerts an impulsive pressure equal to mu on the boundary before the component of velocity of its centre of gravity normal to the boundary is reduced to zero. Thus the contribution to the total impulsive pressure exerted on the area dS in time dt from this cause is

$$mu \times udtdS \times \nu\sqrt{(h^3m^3/\pi^3)}e^{-hm(u^2+v^2+w^2)}dudvdw \qquad (10)$$

The total pressure exerted in bringing the centres of gravity of all the colliding molecules to rest normally to the boundary is obtained by first integrating this expression with respect to u, v, w, the limits being all values for which collisions are possible (namely from $-\infty$ to 0 for u, and from $-\infty$ to $+\infty$ for v and w), and then summing for all kinds of molecules in the gas. Further impulsive pressures are required to restart into motion all the molecules which have undergone collision. The aggregate amount of these pressures is clearly the sum of the momenta, normal to the boundary, of all molecules which have left dS within a time dt, and this will be given by expression (10), integrated with respect to u from 0 to ∞, and with respect to v and w from $-\infty$ to $+\infty$, and then summed for all kinds of molecules in the gas. On combining the two parts of the pressure which have been calculated, the aggregate impulsive pressure on dS in time dt is found to be

$$\Sigma dt\, dS \iiint_{-\infty}^{+\infty} \nu\sqrt{(h^3m^3/\pi^3)}e^{-hm(u^2+v^2+w^2)}mu^2dudvdw,$$

where Σ denotes summation over all kinds of molecules. This is equivalent to a steady pressure p_1 per unit area where

$$p_1 - \Sigma \iiint_{-\infty}^{+\infty} \nu\sqrt{(h^3m^3/\pi^3)}e^{-hm(u^2+v^2+w^2)}mu^2dudvdw.$$

Clearly the integral is the sum of the values of mu^2 for all the molecules of the first kind in unit volume, thus

$$p = \nu\,\overline{mu^2} + \nu'\,\overline{m'u^2} + \dots \qquad (11)$$

On substituting from equations (7) and (8), this expression assumes the forms

$$\begin{aligned} p &= (\nu+\nu'+\dots)/2h \qquad (12)\\ &= (\nu+\nu'+\dots)\mathrm{RT} \qquad (13)\end{aligned}$$

Molecular Velocities.

The number of molecules per unit volume in a gas at normal temperature and pressure is known to be about $2{\cdot}75\times 10^{19}$. If in formula (13) we put $p=1{\cdot}013\times 10^6$, $(\nu+\nu'+\dots)=2{\cdot}75\times 10^{19}$ $\mathrm{T}=273$, we obtain $\mathrm{R}=1{\cdot}35\times 10^{-16}$ and this enables us to determine the mean velocities produced by heat motion in molecules of any given *mass*. For molecules of known gases the calculation is still easier. If ρ is the density corresponding to pressure p, we find that formula (11) assumes the form

$$p = \tfrac{1}{3}\rho \mathrm{C}^2,$$

where C is a velocity such that the gas would have its actual translational energy if each molecule moved with the same velocity C. By substituting experimentally determined pairs of values of p and ρ we can calculate C for different gases, and so obtain a knowledge of the magnitudes of the molecular velocities. For instance, it is found that

for hydrogen at	0° Cent.	C = 183,900	cms.	per sec.
,, air ,,	15° ,,	C = 49,800	,,	,, ,,
,, mercury vapour at	0° ,,	C = 18,500	,,	,, ,,

and other velocities can readily be calculated.

"Brownian Movements."

From the value $\mathrm{R}=1{\cdot}35\times 10^{-16}$ it is readily calculated that a molecule, or aggregation of molecules, of mass 10^{-12} grammes, ought to have a mean velocity of about 2 millimetres a second at 0° C. Such a velocity ought accordingly to be set up in a particle of 10^{-12} grammes mass immersed in air or liquid at 0° C., by the continual jostling of the surrounding molecules or particles. A particle of this mass is easily visible microscopically, and a velocity of 2 mm. per second would of course be visible if continued for a sufficient length of time. Each bombardment will, however, change the motion of the particle, so that changes are too frequent for the separate motions to be individually visible. But it can be shown that from the aggregation of these separate short motions the particle ought to have a resultant motion, described with an average velocity which, although much smaller than 2 mm. a second, ought still to be microscopically visible. It has been shown by R. von. S. Smoluchowski (*Ann. d. Phys.*, 1906, 21, p. 756) that this theoretically predicted motion is simply that seen in the "Brownian movements" first observed by the botanist Robert Brown in 1827. Thus the "Brownian movements" provide visual demonstration of the reality of the heat-motion postulated by the kinetic theory.

Pressure, Volume and Temperature Relations.

Dalton's Law.—The pressure as given by formula (12) can be written as the sum of a number of separate terms, one for each gas in the mixture. Hence we have Dalton's law: *The pressure of a mixture of gases is the sum of the pressures which would be exerted separately by the several constituents if each alone were present.*

Avogadro's Law.—From formula (13) it appears that $\nu+\nu'+\dots$, the total number of molecules per unit volume, is determined when p, T and the constant R are given. Hence we have Avogadro's law: *Different gases, at the same temperature and pressure, contain equal numbers of molecules per unit volume.*

Boyle's and Charles' Laws.—If v is the volume of a homogeneous mass of gas, and N the total number of its molecules, $\mathrm{N}=v(\nu+\nu'+\dots)$, so that

$$pv = \mathrm{RNT}. \qquad (14)$$

In this equation we have the combined laws of Boyle and Charles: *When the temperature of a gas is kept constant the pressure varies inversely as the volume, and when the volume is kept constant the pressure varies as the temperature.*

Since the volume at constant pressure is exactly proportional to the absolute temperature, it follows that the coefficients of expansion of all gases ought, to within the limits of error introduced by the assumptions on which we are working, to have the same value 1/273.

Van der Waals's Equation.—The laws which have just been stated are obeyed very approximately, but not with perfect accuracy, by all gases of which the density is not too great or the temperature too low. Van der Waals, in a famous monograph, *On the Continuity of the Liquid and Gaseous States* (Leiden, 1873), has shown that the imperfections of equation (14) may be traced to two causes:—

(i.) The calculation has not allowed for the finite size of the molecules, and their consequent interference with one another's motion, and

(ii.) The calculation has not allowed for the field of inter-molecular force between the molecules, which, although small, is known to have a real existence. The presence of this field of force results in the molecules, when they reach the boundary, being acted on by forces in addition to those originating in their impact with the boundary.

To allow for the first of these two factors, Van der Waals finds that v in equation (14) must be replaced by $v-b$, where b is four times the aggregate space occupied by all the molecules, while to allow for the second factor, p must be replaced by $p+a/v^2$. Thus the pressure is given by the equation

$$(p+a/v^2)\,(v-b) = \mathrm{RNT},$$

which is known as Van der Waals's equation. This equation is found experimentally to be capable of representing the relation between p, v, and T over large ranges of values. (See CONDENSATION OF GASES.)

Calorimetry.

Let us consider a single gas, consisting of N similar molecules in a volume v, and let the energy of each molecule, as in formula (2) be given by

$$\begin{aligned} \mathrm{E} &= \tfrac{1}{2}\sum_{\mathrm{N}}(mu^2+mv^2+mw^2+a_1\theta_1{}^2+\dots a_n\theta_n{}^2) \qquad (15)\\ &= \mathrm{N}(n+3)/4h \text{ by equation (7)}\\ &= \tfrac{1}{2}(n+3)\mathrm{RNT}. \qquad (16)\end{aligned}$$

Let a quantity dQ of energy, measured in work units, be absorbed by the gas from some external source, so that its pressure, volume and temperature change. The equation of energy is

$$dQ = dE + pdv, \qquad (17)$$

expressing that the total energy dQ is used partly in increasing the internal energy of the gas, and partly in expanding the gas against the pressure p. If we take $p=\mathrm{RNT}/v$ from equation (14) and substitute for E from equation (16), this last equation becomes

$$dQ = \tfrac{1}{2}(n+3)\mathrm{RN}d\mathrm{T} + \mathrm{RNT}dv/v, \qquad (18)$$

which may be taken as the general equation of calorimetry, for a gas which accurately obeys equation (14).

Second Law of Thermodynamics.—If we divide throughout by T, we obtain

$$\frac{dQ}{\mathrm{T}} = \tfrac{1}{2}(n+3)\mathrm{RN}\frac{d\mathrm{T}}{\mathrm{T}} + \mathrm{RN}\frac{dv}{v},$$

showing that dQ/T is a perfect differential. This not only verifies that the second law of thermodynamics is obeyed, but enables us to identify T with the absolute thermodynamical temperature.

Specific Heats.

If the volume of the gas is kept constant, we put $dv=0$ in equation (18) and $dQ=\mathrm{JC}_v\mathrm{N}md\mathrm{T}$, where C_v is the specific heat of the gas at constant volume and J is the mechanical equivalent of heat. We obtain

$$\mathrm{C}_v = \tfrac{1}{2}(n+3)\mathrm{R/J}m. \qquad (19)$$

On the other hand, if the pressure of the gas is kept constant throughout the motion, T/v is constant and $dQ=JC_pNmdT$, whence

$$C_p=\tfrac{1}{2}(n+5)R/Jm. \qquad (20)$$

By division of the values of C_p and C_v we find for γ, the ratio of the specific heats.

$$\gamma=1+2/(n+3). \qquad (21)$$

The comparison of this formula with experiment provides a striking confirmation of the truth of the kinetic theory but at the same time discloses the most formidable difficulty which the theory has so far had to encounter.

On giving different values to n in formula (21), we obtain the values for γ:

$$\begin{array}{lllllll} n = & 0, & 1, & 2, & 3, & 4, & 5, \\ \gamma = & 1{\cdot}66, & 1{\cdot}5, & 1{\cdot}4, & 1{\cdot}33, & 1{\cdot}28, & 1{\cdot}25,\ \&c. \end{array}$$

Thus, to within the degree of approximation to which our theory is accurate, the value of γ for every gas ought to be one of this series. The following are the values of γ for gases for which γ can be observed with some accuracy;—

Mercury	1·66	Nitrogen	1·40
Krypton	1·66	Carbon monoxide	1·41
Helium	1·65	Hydrogen	1·40
Argon	1·62	Oxygen	1·40
Air	1·40	Hydrochloric acid	1·39

It is clear that for the first four gases $n=0$, while for the remainder $n=2$. To examine what is meant by a zero value of n we refer to formula (15). The value of n is the number of terms in the energy of the molecule beyond that due to translation. Thus when $n=0$, the whole energy must be translational: there can be no energy of rotation or of internal motion. The molecules of gases for which $n=0$ must accordingly be spherical in shape and in internal structure, or at least must behave at collisions as though they were spherical, for they would otherwise be set into rotation by the forces experienced at collisions. In the light of these results it is of extreme significance that the four gases for which $n=0$ are all believed to be monatomic: the molecules of these gases consist of single atoms. Moreover, these four are the only monatomic gases for which the value of γ is known, so that the only atoms of which the shape can be determined are found to be spherical. It is at least a plausible conjecture, until the contrary is proved, that the atoms of all elements are spherical.[1]

The next value which occurs is $n=2$. The kinetic energy of the molecules of these gases must contain two terms in addition to those representing translational energy. For a rigid body the kinetic energy will, in general, consist of three terms $(A\omega_1^2+B\omega_2^2+C\omega_3^2)$ in addition to the translational energy. The value $n=2$ is appropriate to bodies of which the shape is that of a solid of revolution, so that there is no rotation about the axis of symmetry. We must accordingly suppose that the molecules of gases for which $n=2$ are of this shape. Now this is exactly the shape which we should expect to find in molecules composed of two spherical atoms distorting one another by their mutual forces, and all gases for which $n=2$ are diatomic.

No molecule could possibly be imagined for which n had a negative value or the value $n=1$. The theory therefore passes a crucial test when it is discovered that no gases exist for which n is either negative or unity. On the other hand, the theory encounters a very serious difficulty in the fact that all molecules possess a great number of possibilities of internal motion, as is shown by the number of distinct lines in their spectra both of emission and of absorption. So far as is known, each line in the spectrum of, say, mercury, represents a possibility of a distinct vibration of the mercury atom, and accordingly provides two terms (say $\alpha\dot{\phi}^2+\beta\phi^2$, where ϕ is the normal co-ordinate of the vibration) in the expression for the energy of the molecule. There are many thousands of lines in the mercury spectrum, so that from this evidence it would appear that for mercury vapour n ought to be very great, and γ almost equal to unity. Instead of this we have $n=0$, and $\gamma=1\frac{2}{3}$. As a step towards removing this difficulty we notice that the energy of a vibration such as is represented by a spectral line has the peculiarity of being unable to exist (so far as we know) without suffering dissipation into the ether. This energy, therefore, comes under a different category from the energy for which the law of equipartition was proved, for in proving this law conservation of energy was assumed. The difficulty is further diminished when it is proved, as it can be proved,[2] that the modes of energy represented in the atomic spectrum acquire energy so slowly that the atom might undergo collisions with other atoms for centuries before being set into oscillations which would possess an appreciable amount of energy. In fact the proved tendency for the gas to pass into the "normal state" in which there is equipartition of energy, represents in this case nothing but the tendency for the translational energy to become dissipated into the energy of innumerable small vibrations. We find that this dissipation, although undoubtedly going on, proceeds with extreme slowness, so that the vibrations pass their energy on to the ether as rapidly as they acquire it, and the "normal state" is never established. These considerations suggest that the difficulty which has been pointed out may be apparent rather than real. At the same time this difficulty is only one aspect of a wider difficulty which cannot be lightly passed over; Maxwell himself regarded it as the principal obstacle in the way of the full acceptance of the theory of which he was so largely the author. (J. H. JE.)

MOLE-RAT, the name of a group of blind burrowing rodents, typified by the large grey *Spalax typhlus* of eastern Europe and Egypt, which represents the Old World family *Spalacidae*. All the mole-rats of the genus *Spalax* are characterized by the want of distinct necks, small or rudimentary ears and eyes, and short limbs provided with powerful digging claws. There are three pairs of cheek-teeth which are rooted, and show folds of enamel on the crown. Mole-rats are easily recognized by the peculiarly flattened head, in which the minute eyes are covered with skin, the wart-like ears, and rudimentary tail; they make burrows in sandy soil, and feed on bulbs and roots. Bamboo-rats, of which one genus (*Rhizomys*) is Indian and Burmese, and the other (*Tachyoryctes*) East African, differ by the absence of skin over the eyes, the presence of short ears, and a short, sparsely-haired tail. They burrow either among tall grass, or at the roots of trees (see RODENTIA).

MOLE-SHREW, any individual of the genera *Urotrichus* and *Uropsilus* (see INSECTIVORA). These animals, which are sometimes called shrew-moles, are not moles with shrew-like habits, but shrews with the burrowing habits of moles and resembling them in appearance.

MOLESKIN, a term employed not only for the skin of a mole but also, from a real or fancied resemblance, for a stout heavy cotton fabric of leathery consistence woven as a satin twill on a strong warp. It is shorn before being dyed or bleached. Being of an exceedingly durable and economical texture, it has been much worn by working-men, especially outdoor labourers. It is also used for gun-cases, carriage-covers, and several purposes in which a fabric capable of resisting rough usage is desirable.

MOLESWORTH, MARY LOUISA (1839–), Scottish writer, daughter of Major-General Stewart, of Strath, N.B., was born in Rotterdam on the 29th of May 1839, and was educated in Great Britain and abroad. In 1861 Miss Stewart married Major R. Molesworth. Her first novels, *Lover and Husband* (1869) to *Cicely* (1874), appeared under the pseudonym of "Ennis Graham." Mrs Molesworth is best known as a writer of books for the young, such as *Tell Me a Story* (1875), *Carrots* (1876), and *The Cuckoo Clock* (1877).

MOLESWORTH, ROBERT MOLESWORTH, 1ST VISCOUNT (1656–1725), came of an old Northamptonshire family. His father Robert (d. 1656) was a Cromwellian who made a fortune in Dublin, and he himself supported William of Orange and in 1695 became a prominent member of the Irish privy council. In 1716 he was created a viscount. He was succeeded by his two sons, John, 2nd viscount (1679–1726), and Richard 3rd viscount (1680–1758), the latter of whom saved Marlborough's life at the battle of Ramillies and rose to be a field-marshal. The 3rd viscount's son Richard Nassau (1748–1793) succeeded to the title, which has descended accordingly.

A great-grandson of the 1st viscount, JOHN EDWARD NASSAU MOLESWORTH (1790–1877), vicar of Rochdale, was a well-known High Churchman and controversialist; and two of his sons became prominent men—WILLIAM NASSAU MOLESWORTH (1816–1890), author of *History of England 1830–1871* (1871–1873), *History of the Reform Bill* (1865), and *History of the Church of*

---

[1] Very significant confirmation of this conjecture is obtained from a study of the specific heats of the elements in the solid state. If a solid body is regarded as an aggregation of similar atoms each of mass m, its specific heat C is given, as in formula (19) by $C=\frac{1}{2}(n+3)R/Jm$. From Dulong and Petit's law that Cm is the same for all elements, it follows that $n+3$ must be the same for all atoms. Moreover, the value of Cm shows that $n+3$ must be equal to six. Now if the atoms are regarded as points or spherical bodies oscillating about positions of equilibrium, the value of $n+3$ is precisely six, for we can express the energy of the atom in the form

$$E=\tfrac{1}{2}\left(mu^2+mv^2+mw^2+x^2\frac{\partial^2V}{\partial x^2}+y^2\frac{\partial^2V}{\partial y^2}+z^2\frac{\partial^2V}{\partial z^2}\right),$$

where V is the potential and x, y, z are the displacements of the atom referred to a certain set of orthogonal axes.

[2] J. H. Jeans, *Dynamical Theory of Gases*, ch. ix.

England (1882); and **Sir Guilford Molesworth** (b. 1828), an eminent engineer and economist.

MOLESWORTH, SIR WILLIAM, Bart. (1810–1855), English politician, son of the 7th baronet, was born in London on the 23rd of May 1810, and in 1823 succeeded to the baronetcy. At Cambridge he fought a duel with his tutor, and for some time studied abroad. On the passing of the Reform Act of 1832 he was returned to parliament for the eastern division of Cornwall, to support the ministry of Lord Grey. Through Charles Buller he made the acquaintance of Grote and James Mill, and in April 1835 he founded, in conjunction with Roebuck, the *London Review*, as an organ of the "Philosophic Radicals." After the publication of two volumes he purchased the *Westminster Review*, and for some time the united magazines were edited by him and J. S. Mill. From 1837 to 1841 Sir William Molesworth sat for Leeds, and acquired considerable influence in the House of Commons by his speeches and by his tact in presiding over the select committee on transportation. But his Radicalism made little impression either on the house or on his constituency. From 1841 to 1845 he had no seat in parliament, occupying his leisure time in editing the works in Latin and English of Thomas Hobbes of Malmesbury, a recreation which cost him no less than £6000. In 1845 he was returned for Southwark, and retained that seat until his death. On his return to parliament he devoted special attention to the condition of the colonies, and was the ardent champion of their self-government. In January 1853 Lord Aberdeen included him in the cabinet as first commissioner of works, the chief work by which his name was brought into prominence at this time being the construction of the new Westminster Bridge; he also was the first to open Kew Gardens on Sundays. In July 1855 he was made colonial secretary, but he died on the 22nd of October. Molesworth was for many years a great friend of Mr and Mrs Grote, and Mrs Grote's privately printed work on *The Philosophical Radicals* (1866) contains an account of his life. He married in 1844, but had no children, and the baronetcy passed to a cousin. His sister (d. 1910) married Richard Ford, famous for his *Handbook of Spain.*

A *Life* by Mrs Fawcett was published in 1903. A full pedigree of the Molesworth family is printed in Sir John Maclean's *Trigg Minor*, vol. i.; the titles of his speeches and works may be found in the *Bibl. Cornubiensis*, vol. i. and iii.

MOLFETTA, a seaport and episcopal see of Apulia, Italy, in the province of Bari, from which it is 16 m. N.N.W. by rail. Pop. (1901), 42,363. The old cathedral of S. Conrad is a Romanesque structure. The old town is surrounded by walls, and has medieval houses; the new town is more spacious, and is an active seaport. The origin of Molfetta is uncertain, though there was a neolithic settlement here. The town was given by Charles V. to the duke of Termoli in 1522, and during his lordship it was sacked by the French under Lautrec. In 1631 Cesare Gonzaga took the title of duke of Guastalla and prince of Molfetta; but in 1640 the fief was sold to the Spinola family, and in 1798 incorporated with the royal domain. The bishopric is directly subject to the papal see.

MOLIÈRE (1622–1673), the *nom de théâtre* chosen, for some undiscovered reason, by the great French dramatist Jean Baptiste Poquelin, and ever since substituted for his family name. He was born in Paris, probably in January 1622. The baptismal certificate which is usually, and almost with absolute certainty, accepted as his is dated 15th January 1622, but it is not possible to infer that he was born on the day of his christening. The exact place of his birth is also disputed, but it seems tolerably certain that he saw the light in a house of the Rue St Honoré. His father was Jean Poquelin, an upholsterer, who, in 1631, succeeded his own uncle as "valet tapissier de chambre du roi." The family of Poquelin came from Beauvais, where for some centuries they had been prosperous tradesmen. The legend of their Scotch descent seems to have been finally disproved by the researches of M. E. Révérend du Mesnil. The mother of Molière was Marie Cressé; and on his father's side he was connected with the family of Mazuel, musicians attached to the court of France. In 1632 Molière lost his mother; his father married again in 1633. The father possessed certain shops in the covered Halle de la Foire, Saint Germain des Prés, and the biographers have imagined that Molière might have received his first bent towards the stage from the spectacles offered to the holiday people at the fair. Of his early education little is known; but it is certain that his mother possessed a Bible and Plutarch's *Lives*, books which an intelligent child would not fail to study. In spite of a persistent tradition, there is no reason to believe that the later education of Molière was neglected. "Il fit ses humanitez au collège de Clermont," says the brief life of the comedian published by his friend and fellow-actor, La Grange, in the edition of his works printed in 1682. La Grange adds that Molière "eut l'advantage de suivre M. le Prince de Conti dans toutes ses classes." As Conti was seven years younger than Molière, it is not easy to understand how Molière came to be the school contemporary of the prince. Among more serious studies the Jesuit fathers encouraged their pupils to take part in *ballets*, and in later life Molière was a distinguished master of this sort of entertainment. According to Grimarest, the first writer who published a life of Molière in any detail (1705), he not only acquired "his humanities," but finished his "philosophy" in five years. He left the Collège de Clermont in 1641, the year when Gassendi, a great contemner of Aristotle, arrived in Paris. The *Logic* and *Ethics* of Aristotle, with his *Physics* and *Metaphysics*, were the chief philosophical textbooks at the Collège de Clermont. But when he became the pupil of Gassendi (in company with Cyrano de Bergerac, Chapelle, and Hesnaut), Molière was taught to appreciate the atomic philosophy of Lucretius. There seems no doubt that Molière began, and almost or quite finished, a translation of the *De natura rerum.* According to a manuscript note of Trallage, published by M. Paul Lacroix, the manuscript was sold by Molière's widow to a bookseller. His philosophic studies left a deep mark on the genius of Molière. In the *Jugement de Pluton sur les deux parties des nouveaux dialogues des morts* (1684), the verdict is "que Molière ne parleroit point de philosophie." To "talk philosophy" was a favourite exercise of his during his life, and his ideas are indicated with sufficient clearness in several of his plays. There seems no connexion between them and the opinions of "Molière le Critique" in a dialogue of that name, published in Holland in 1709. From his study of philosophy, too, he gained his knowledge of the ways of contemporary pedants: of Pancrace the Aristotelian, of Marphorius the Cartesian, of Trissotin, "qui s'attache pour l'ordre au Péripatétisme," of Philaminte, who loves Platonism, of Belise, who relishes "les petits corps," and Armande, who loves "les tourbillons." Grimarest has an amusing anecdote of a controversy in which Molière, defending Descartes, chose a lay-brother of a begging order for umpire, while Chapelle appealed to the same expert in favour of Gassendi. His college education over, Molière studied law, and there is even evidence—that of tradition in Grimarest, and of Le Boulanger de Chalussay, the libellous author of a play called *Élomire hypochondre*—to prove that he was actually called to the bar. More trustworthy is the passing remark in La Grange's short biography (1682), "*au sortir des écoles de droit*, il choisit la profession de comédien." Before joining a troop of half-amateur comedians, however, Molière had some experience in his father's business. In 1637 his father had obtained for him the right to succeed to his own office as "valet tapissier de chambre du roi." The document is mentioned in the inventory of Molière's effects, taken after his death. When the king travelled the *valet tapissier* accompanied him to arrange the furniture of the royal quarters. There is very good reason to believe (Loiseleur, *Points obscurs*, p. 94) that Molière accompanied Louis XIII. as his *valet tapissier* to Provence in 1642. It is even not impossible that Molière was the young *valet de chambre* who concealed Cinq Mars just before his arrest at Narbonne, on the 13th of June 1642. But this is part of the romance rather than of the history of Molière. Our next glimpse of the comedian we get in a document of 6th January 1643. Molière acknowledges the receipt of money due to him from his deceased mother's estate, and gives up his claim to succeed his father as "valet de chambre du roi." On the 28th of December of the same year we learn, again from documentary evidence, that Jean Baptiste Poquelin, with Joseph Béjard, Madeleine Béjard, Geneviève Béjard, and others, have hired a tennis-court and fitted it up as a stage for dramatic performances. The company called themselves L'Illustre Théâtre, *illustre* being then almost a slang word, freely employed by the writers of the period.

We now reach a very important point in the private history of Molière, which it is necessary to discuss at some length in defence of the much maligned character of a great writer and a good man. Molière's connexion with the family of Béjard brought him much unhappiness. The father of this family, Joseph Béjard the elder, was a needy man, with eleven children at least. His wife's name was Marie Hervé. The most noted of his children, companions of Molière, were Joseph, Madeleine, Geneviève, and Armande. Of these, Madeleine was a woman of great talent as an actress, and Molière's friend, or perhaps mistress, through all the years of his wanderings. Now, on the 14th of February 1662 (for we must here leave the chronological order of events), Molière married Armande Claire Élisabeth Grésinde Béjard. His enemies at that time, and a number of his biographers in our own day, have attempted to prove that Armande Béjard was not the sister, but the daughter of Madeleine, and even that Molière's wife may have been his own daughter by Madeleine Béjard. The arguments of M. Arsène Houssaye in support of this abominable theory are based on reckless and ignorant confusions, and do not deserve criticism. But the system of M. Loiseleur is more serious, and he goes no further than the idea that Madeleine was the mother of Armande. This, certainly, was the opinion of tradition, an opinion based on the slanders of Montfleury, a rival of Molière's, on the authority of the spiteful and anonymous author of *La Fameuse comédienne* (1688), and on the no less libellous play, *Élomire hypochondre*. In 1821 tradition received a shock, for Beffara then discovered Molière's "acte de mariage," in which Armande, the bride, is spoken of as the sister of Madeleine Béjard, by the same father and mother. The old scandal, or part of it, was revived by M. Fournier and M. Bazin, but received another blow in 1863. M. Soulié then discovered a legal document of the 10th of March 1643, in which the widow of Joseph Béjard renounced, in the name of herself and her children, his inheritance, chiefly a collection of unpaid bills. Now in this document all the children are described as minors, and among them is "une petite non encore baptisée." This little girl, still not christened in March 1643, is universally recognized as the Armande Béjard afterwards married by Molière. We reach this point, then, that when Armande was an infant she was acknowledged as the sister, not as the daughter, of Madeleine Béjard. M. Loiseleur refuses, however, to accept this evidence. Madeleine, says he, had already become the mother, in 1638, of a daughter by Esprit Raymond de Moirmoron, comte de Modène, and chamberlain of Gaston duc d'Orléans, brother of Louis XIII. In 1642 Modène, who had been exiled for political reasons, "was certain to return, for Richelieu had just died, and Louis XIII. was likely to follow him." Now Madeleine was again—this is M. Loiseleur's hypothesis—about to become a mother, and if Modène returned, and learned this fact, he would not continue the liaison, still less would he marry her—which, by the way, he could not do, as his wife was still alive. Madeleine, therefore, induced her mother to acknowledge the little girl as her own child. In the first place, all this is pure unsupported hypothesis. In the second place, it has always been denied that Béjard's wife could have been a mother in 1643, owing to her advanced age, probably fifty-three. But M. Loiseleur himself says that Marie Hervé was young enough to make the story "sufficiently probable." If it was probable, much more was it possible. M. Loiseleur supports his contention by pointing out that two of the other children, described as legally minors, were over twenty-five, and that their age was understated to make the account of Armande's birth more probable. Nothing is less likely than that Modène would have consulted this document to ascertain the truth about the parentage of Armande, yet M. Loiseleur's whole theory rests on that extreme improbability. It must also be observed that the date of the birth of Joseph Béjard is unknown, and he *may* have been, and according to M. Jal (*Dictionnaire critique*, p. 178) *must* have been, a minor when he was so described in the document of the 10th of March 1643, while Madeleine had only passed her twenty-fifth birthday, her legal majority, by two months. This view of Joseph's age is supported by Bouquet (*Molière à Rouen*, p. 77). M. Loiseleur's only other proof is that Marie Hervé gave Armande a respectable dowry, and that, as we do not know whence the money came, it must have come from Madeleine. The tradition in Grimarest, which makes Madeleine behave *en femme furieuse*, when she heard of the marriage, is based on a juster appreciation of the character of women. It will be admitted, probably, that the reasons for supposing that Molière espoused the daughter of a woman who had been his mistress (if she had been his mistress) are flimsy and inadequate. The affair of the dowry is insisted on by M. Livet (*La Fameuse comédienne*, reprint of 1877, p. 143). But M. Livet explains the dowry by the hypothesis that Armande was the daughter of Madeleine and the comte de Modène, which exactly contradicts the theory of M. Loiseleur, and is itself contradicted by dates, at least as understood by M. Loiseleur. Such are the conjectures by which the foul calumnies of Molière's enemies are supported in the essays of modern French critics.

Michelet accepted the scandal apparently as a buttress to his charges against Louis XIV. and Madame (*Histoire de France*, 1879, xv. 63, 64, 332).

To return to the order of events, Molière passed the year 1643 in playing with and helping to manage the Théâtre Illustre. The company acted in various tennis-courts, with very little success. Molière was actually arrested by the tradesman who supplied candles, and the company had to borrow money from one Aubrey to release their leader from the Grand Châtelet (Aug. 13, 1645). The process of turning a tennis-court into a theatre was somewhat expensive, even though no seats were provided in the pit. The troupe was for a short time under the protection of the duc d'Orléans, but his favours were not lucrative. The duc de Guise, according to some verses printed in 1646, made Molière a present of his cast-off wardrobe. But costume was not enough to draw the public to the tennis-court theatre of the Croix Noire, and empty houses at last obliged the Théâtre Illustre to leave Paris at the end of 1646.

"Nul animal vivant n'entra dans nôtre salle," says the author of the scurrilous play on Molière, *Élomire hypochondre*. But at that time some dozen travelling companies found means to exist in the provinces, and Molière determined to play among the rural towns. The career of a strolling player is much the same at all times and in all countries. The *Roman comique* of Scarron gives a vivid picture of the adventures and misadventures, the difficulty of transport, the queer cavalcade of horses, mules, and lumbering carts that drag the wardrobe and properties, the sudden metamorphosis of the tennis-court, where the balls have just been rattling, into a stage, the quarrels with local squires, the disturbed nights in crowded country inns, all the loves and wars of a troupe on the march. Perrault tells us what the arrangements to the theatre were in Molière's early time. Tapestries were hung round the stage, and entrances and exits were made by struggling through the heavy curtains, which often knocked off the hat of the comedian, or gave a strange cock to the helmet of a warrior or a god. The lights were candles stuck in tin sconces at the back and sides, but luxury sometimes went so far that a chandelier of four candles was suspended from the roof. At intervals the candles were let down by a rope and pulley, and any one within easy reach snuffed them with his fingers. A flute and tambour, or two fiddlers, supplied the music. The highest prices were paid for seats in the *dedans* (cost of admission fivepence); for the privilege of standing up in the pit twopence-halfpenny was the charge. The doors were opened at one o'clock, the curtain rose at two.

The nominal director of the Théâtre Illustre in the provinces was Du Fresne; the most noted actors were Molière, the Béjards, and Du Parc, called Gros René. It is extremely difficult to follow exactly the line of march of the company. They played at Bordeaux, for example, but the date of this performance, when Molière (according to Montesquieu) failed in tragedy and was pelted, is variously given as 1644–1645 (Trallage), 1647 (Loiseleur), 1648–1658 (Lacroix). Perhaps the theatre prospered better elsewhere than in Paris, where the streets were barricaded in these early days of the war of the Fronde. We find Molière at Nantes in 1648, at Fontenay-la-Compte, and in the spring of 1649 at Agen, Toulouse, and probably at Angoulême and Limoges. In January 1650 they played at Narbonne, and between 1650 and 1653 Lyons was the headquarters of the troupe. In January 1653, or perhaps 1655, Molière gave *L'Étourdi* at Lyons, the first of his finished pieces, as contrasted with the slight farces with which he generally diverted a country audience. It would be interesting to have the precise date of this piece, but La Grange (1682) says that "in 1653 Molière went to Lyons, where he gave his first comedy, *L'Étourdi*," while in his *Registre* La Grange enters the year as 1655. At Lyons de Brie and his wife, the famous Mlle de Brie, entered the troupe, and du Parc married the "marquise" de Gorla, better known as Mlle du Parc. The libellous author of *La Fameuse comédienne* reports that Molière's heart was the shuttlecock of the beautiful du Parc and de Brie, and the tradition has a persistent life. Molière's own opinion of the ladies and men of his company may be read between the lines of his *Impromptu de Versailles.* In 1653 Prince de Conti, after many political adventures, was residing at La Grange, near Pézénas, in Languedoc, and chance brought him into relations with his old schoolfellow Molière. Conti had for first gentleman of his bed-chamber the abbé Daniel de Cosnac, whose memoirs now throw light for a moment on the fortunes of the wandering troupe. Cosnac engaged the company "of Molière and of La Béjart"; but another company, that of Cormier, nearly intercepted the favour of the prince. Thanks to the resolution of Cosnac, Molière was given one chance of appearing on the private theatre of La Grange. The excellence of his acting, the splendour of the costumes, and the insistence of Cosnac, and of Sarrasin, Conti's secretary, gained the day for Molière, and a pension was assigned to his company (Cosnac, *Mémoires*, i. 128; Paris, 1852). As Cosnac proposed to pay Molière a thousand crowns of his own money to recompense him in case he was supplanted by Cormier, it is obvious that his profession had become sufficiently lucrative. In 1654, during the session of the estates of Languedoc, Molière and his company played at Montpellier. Here Molière danced in a *ballet* (*Le Ballet des incompatibles*) in which a number of men of rank took part, according to the fashion of the time. Molière's own *rôles* were those of the Poet and the Fishwife. The sport of the little piece is to introduce opposite characters, dancing and singing together. Silence dances with six women, Truth with four courtiers, Money with a poet, and so forth. Whether the ballet, or any parts of it, are by Molière, is still disputed (*La Jeunesse de Molière, suivie du ballet des incompatibles*, P. L. Jacob, Paris, 1858). In April 1655 it is certain that the troupe was at Lyons, where they met and hospitably entertained a profligate buffoon, Charles d'Assoucy, who informs the ages that Molière kept open house, and "une table bien garnie." November 1655 found Molière at Pézénas, where the estates of Languedoc were convened, and where local tradition points out the barber's chair in which the poet used to sit and study character. The longest of Molière's extant autographs is a receipt, dated at Pézénas, on the 4th of February 1656, for 6000 livres, granted by the estates of Languedoc. This year was notable for the earliest representation, at Béziers, of Molière's second finished comedy, the *Dépit amoureux.* Conti now (1656) began to "make his soul." Almost his first act of penitence was to discard Molière's troupe (1657), which consequently found that the liberality of the estates of Languedoc was dried up for ever. Conti's relations with Molière must have definitively closed long before 1666, when the now pious prince wrote a treatise against the stage, and especially charged his old schoolfellow with keeping a new school, a school of atheism (*Traité de la comédie,* p. 24; Paris, 1666). Molière was now (1657) independent of princes and their favour. He went on a new circuit to Nismes, Orange and Avignon, where he met another old class-mate, Chapelle, and also encountered the friend of his later life, the painter Mignard. After a later stay at Lyons, ending with a piece given for the benefit of the poor on the 27th of February 1658, Molière passed to Grenoble, returned to Lyons, and is next found in Rouen, where, we should have said, the Théâtre Illustre had played in 1643 (F. Bouquet, *La Troupe de Molière à Rouen*, p. 90; Paris, 1880). At Rouen Molière must have made or renewed the acquaintance of Pierre and Thomas Corneille. His company had played pieces by Corneille at Lyons and elsewhere. The real business of the comedian in Rouen was to prepare his return to Paris. "After several secret journeys thither he was fortunate enough to secure the patronage of Monsieur, the king's only brother, who granted him his protection, and permitted the company to take his name, presenting them as his servants to the king and the queen mother" (Preface to La Grange's edition of 1682). The troupe appeared for the first time before Louis XIV. in a theatre arranged in the old Louvre (Oct. 24, 1658).

Molière was now thirty-six years of age. He had gained all the experience that fifteen years of practice could give. He had seen men and cities, and noted all the humours of rural and civic France. He was at the head of a company which, as La Grange, his friend and comrade, says, "sincerely loved him." He had the unlucrative patronage of a great prince to back him, and the jealousy of all playwrights, and of the old theatres of the Hôtel de Bourgogne and the Marais, to contend against. In this struggle we can follow him by aid of the *Registre* of La Grange (a brief diary of receipts and payments), and by the help of notices in the rhymed chronicles of Loret.

The first appearance of Molière before the king was all but a failure. *Nicomède*, by the elder Corneille, was the piece, and we may believe that the actors of the Hôtel de Bourgogne, who were present, found much to criticize. When the play was over, Molière came forward and asked the king's permission to act "one of the little pieces with which he had been used to regale the provinces." The *Docteur amoureux*, one of several slight comedies admitting of much "gag," was then performed, and "diverted as much as it surprised the audience." The king commanded that the troupe should establish itself in Paris (Preface, ed. 1682). The theatre assigned to the company was a *salle* in the Petit Bourbon, in a line with the present Rue du Louvre. Some Italian players already occupied the house on Tuesdays, Fridays, and Sundays; the company of Molière played on the other days. The first piece played in the new house (Nov. 3, 1658) was *L'Étourdi.* La Grange says the comedy had a great success, producing seventy pistoles for each actor. The success is admitted even by the spiteful author of *Élomire hypochondre* (Paris, 1670):—

> "Je jouai *l'Étourdi*, qui fut une merveille."

The success, however, is attributed to the farcical element in the play and the acting—the cuckoo-cry of Molière's detractors. The original of *L'Étourdi* is the Italian comedy (1629) *L'Inavvertito*, by Nicolò Barbieri detto Beltrame; Molière pushed rather far his right to "take his own wherever he found it." Had he written nothing more original, the contemporary critic of the *Festin de Pierre* might have said, not untruly, that he only excelled in stealing pieces from the Italians. The piece is conventional: the stock characters of the prodigal son, the impudent valet, the old father occupy the stage. But the dialogue has amazing rapidity, and the vivacity of M. Coquelin to Mascarille made *L'Étourdi* a favourite on the modern stage, though it cannot be read with very much pleasure. The next piece, new in Paris, though not in the provinces, was the *Dépit amoureux* (first acted at Béziers, 1656). The play was not less successful than *L'Étourdi*. It has two parts, one an Italian *imbroglio*; the other, which alone keeps the stage, is the original work of Molière, though, of course, the idea of *amantium irae* is as old as literature. "Nothing so good," says Mr Saintsbury, "had yet been seen on the French stage, as the quarrels and reconciliations of the quartette of master, mistress, valet and soubrette." Even the hostile Le Boulanger de Chalussay (*Élomire hypochondre*) admits that the audience was much of this opinion:—

> "Et de tous les côtés chacun cria tout haut:
> 'C'est la faire et jouer les pièces comme il faut.'"

The same praise was given, perhaps even more deservedly, to *Les Précieuses ridicules* (Nov. 18, 1659). Doubts have been raised as to whether this famous piece, the first true comic satire of contemporary foibles on the French stage, was a new play. La Grange calls it *pièce nouvelle* in his *Registre*; but, as he enters it as the third *pièce nouvelle*, he may only mean that, like *L'Étourdi*, it was new to Paris. The short life of 1682, produced under La Grange's care, and probably written by Marcel the actor, says the *Précieuses* was "made" in 1659. There is another controversy as to whether the ladies of the Hôtel Rambouillet, or merely their *bourgeoises* and rustic imitators, were laughed at. Ménage, in later years at least, professed to recognize an attack on the over-refinement and affectation of the original and, in most ways, honourable *précieuses* of the Hôtel Rambouillet. But Chapelle and Bachaumont had discovered provincial *précieuses*, hyper-aesthetic literary ladies, at Montpellier before Molière's return to Paris; and Furetière, in the *Roman bourgeois* (1666), found Paris full of middle-class *précieuses*, who had survived, or, like their modern counterparts, had thriven on ridicule. Another question is: Did Molière copy from the earlier *Précieuses* of the abbé de Pure? This charge of plagiarism is brought by Somaize, in the preface to his *Véritables précieuses*. De Pure's work was a novel (1656), from which the Italian actors had put together an acting-piece in their manner—that is, a thing of "gag," and improvised speeches. The reproach is interesting only because it proves how early Molière found enemies who, like Thomas Corneille in 1659, accused him of being skilled only in farce, or, like Somaize, charged him with literary larceny. These were the stock criticisms of Molière's opponents as long as he lived. The success of the *Précieuses ridicules* was immense; on one famous occasion the king was a spectator, leaning against the great chair of the dying Cardinal Mazarin. The play can never cease to please while literary affectation exists, and it has a comic force of deathless energy. Yet a modern reader may spare some sympathy for the poor heroines, who do not wish, in courtship, to "begin with marriage," but prefer first to have some less formidable acquaintance with their wooers. Molière's next piece was less important, and more purely farcical, *Sganarelle; ou le cocu imaginaire* (May 28, 1660). The public taste preferred a work of this light nature, and *Sganarelle* was played every year as long as Molière lived. The play was pirated by a man who pretended to have retained all the words in his memory. The counterfeit copy was published by Ribou, a double injury to Molière, as, once printed, any company might act the play. With his habitual good-nature, Molière not only allowed Ribou to publish later works of his, but actually lent money to that knave (Soulié, *Recherches*, p. 287).

On the 11th of October 1660 the Théâtre du Petit Bourbon was demolished by the superintendent of works, without notice given to the company. The king gave Molière the Salle du Palais Royal, but the machinery of the old theatre was maliciously destroyed. Meanwhile the older companies of the Marais and the Hôtel de Bourgogne attempted to lure away Molière's troupe, but, as La Grange declares (*Registre*, p. 26), "all the actors loved their chief, who united to extraordinary genius an honourable character and charming manner, which compelled them all to protest that they would never leave him, but always share his fortunes." While the new theatre was being put in order, the company played in the houses of the great, and before the king at the Louvre. In their new house (originally built by Richelieu) Molière began to play on the 20th of January 1661. Molière now gratified his rivals by a failure. *Don Garcie de Navarre*, a heavy tragi-comedy, which had long lain among his papers, was first represented on the 4th of February 1661. Either Molière was a poor actor outside comedy, or his manner was not sufficiently "stagy," and, as he says, "demoniac," for the taste of the day. His opponents were determined that he could not act in tragi-comedy, and he, in turn, burlesqued their pretentious and exaggerated manner in a later piece. In the *Précieuses* (sc. ix.) Molière had already rallied "les grands comédiens" of the Hôtel Bourgogne. "Les autres," he makes Mascarille say about his own troupe, "sont des ignorants qui récitent comme l'on parle, ils ne savent pas faire ronfler les vers." All this was likely to irritate the *grands comédiens*, and their friends, who avenged themselves on that unfortunate jealous prince, Don Garcie de Navarre. The subject of this unsuccessful drama is one of many examples which show how Molière's mind was engaged with the serious or comic aspects of jealousy, a passion which he had soon cause to know most intimately. Meantime the everyday life of the stage went on, and the doorkeeper of the Théâtre St Germain was wounded by some revellers who tried to force their way into the house (La Grange, *Registre*). A year later, an Italian actor was stabbed in front of Molière's house, where he had sought to take shelter (Campardon, *Nouvelles pièces*, p. 20). To these dangers actors were peculiarly subject: Molière himself was frequently threatened by the marquises and others whose class he ridiculed on the stage, and there seems even reason to believe that there is some truth in the story of the angry marquis who rubbed the poet's head against his buttons, thereby cutting his face severely. The story comes late (1725) into his biography, but is supported by a passage in the contemporary play, *Zélinde* (Paris, 1663, scene viii.). Before Easter, Molière asked for two shares in the profits of his company, one for himself, and one for his wife, if he married. That fatal step was already contemplated (La Grange). On the 24th of June he brought out for the first time *L'École des maris*. The general idea of the piece is as old as Menander, and Molière was promptly accused of pilfering from the *Adelphi* of Terence. One of the *ficelles* of the comedy is borrowed from a story as old, at least, as Boccaccio, and still amusing in a novel by Charles de Bernard. It is significant of Molière's talent that the grotesque and baffled paternal wooer, Sganarelle, like several other butts in Molière's comedy, does to a certain extent win our sympathy and pity as well as our laughter. The next new piece was *Les Fascheux*, a *comédie-ballet*, the Comedy of Bores, played before the king at Fouquet's house at Vaux le Vicomte (Aug. 15–20, 1661). The comedians, without knowing it, were perhaps the real "fascheux" on this occasion, for Fouquet was absorbed in the schemes of his insatiable ambition (*Quo non ascendam?* says his motto), and the king was organizing the arrest and fall of Fouquet, his rival in the affections of La Vallière. The author of the prologue to *Les Fascheux*, Pellisson, a friend of Fouquet's, was arrested with the superintendent of finance. Pellisson's prologue and name were retained in the later editions. In the dedication to the king Molière says that Louis suggested one scene (that of the Sportsman), and in another place he mentions that the piece was written, rehearsed, and played in a fortnight. The fundamental idea of the play, the interruptions by bores, is suggested by a satire of Régnier's, and that by a satire of Horace. Perhaps it may have been the acknowledged suggestions of the king which made gossips declare that Molière habitually worked up hints and *mémoires* given him by persons of quality (*Nouvelles nouvelles*, 1663).

In February 1662 Molière married Armande Béjard. The date is given thus in the *Registre* of La Grange: "Mardy 14, Les Visionnaires, L'École des M.

"Part. Visite chez Mᵉ d'Equeuilly."

And on the margin he has painted a blue circle—his way of recording a happy event—with the words, "mariage de M. de Molière au sortir de la Visite." M. Loiseleur gives the date in one passage as the 29th of February; in another as the 20th of

February. But La Grange elsewhere mentions the date as "Shrove Tuesday," which was, it seems, the 14th of February. Elsewhere M. Loiseleur makes the date of the marriage a vague day "in January." The truth is that the marriage contract is dated the 23rd of January 1662 (Soulié, *Documents*, p. 203). Where it is so difficult to establish the date of the marriage, a simple fact, it must be infinitely harder to discover the truth as to the conduct of Mme Molière. The abominable assertions of the anonymous libel, *Les Intrigues de Molière et celles de sa femme; ou la fameuse comédienne* (1688), have found their way into tradition, and are accepted by many biographers. But M. Livet and M. Bazin have proved that the alleged lovers of Mme Molière were actually absent from France, or from the court, at the time when they are reported, in the libel, to have conquered her heart. A conversation between Chapelle and Molière, in which the comedian is made to tell the story of his wrongs, is plainly a mere fiction, and is answered in Grimarest by another dialogue between Molière and Rohault, in which Molière only complains of a jealousy which he knows to be unfounded. It is noticed, too, that the contemporary assailants of Molière counted him among jealous, but not among deceived, husbands. The hideous accusation brought by the actor Montfleury, that Molière had married his own daughter, Louis XIV. answered by becoming the godfather of Molière's child. The king, indeed, was a firm friend of the actor, and, when Molière was accused of impiety on the production of *Don Juan* (1665) Louis gave him a pension. We need not try to make Mme Molière a *vertu*, as French ladies of the theatre say, but it is certain that the charges against her are unsubstantiated. It is generally thought that Molière drew her portrait in *Le Bourgeois gentilhomme* (acte III. sc. ix.), "elle est capricieuse, mais on souffre tout des belles."

From 1662 onwards Molière suffered the increasing hatred of his rival actors. La Grange mentions the visit of Floridor and Montfleury to the queen mother, and their attempt to obtain equal favour, "la troupe de Molière leur donnant beaucoup de jalouzie" (Aug. 12, 1662). On the 26th of December was played for the first time the admirable *École des femmes*, which provoked a literary war, and caused a shower of "paper bullets of the brain." The innocence of Agnes was called indecency; the sermon of Arnolphe was a deliberate attack on Christian mysteries. We have not the space to discuss the religious ideas of Molière; but both in *L'École des femmes* and in *Don Juan* he does display a bold contempt for the creed of "boiling chaldrons" and of physical hell. A brief list of the plays and pamphlets provoked by *L'École des femmes* is all we can offer in this place.

December 26, 1662.—*École des femmes.*

February 9, 1663.—*Nouvelles nouvelles*, by De Visé. Molière is accused of pilfering from Straparola.

June 1, 1663.—Molière's own piece, *Critique de l'école des femmes.* In this play Molière retorts on the critics, and especially on his favourite butt, the critical marquess.

August 1663.—*Zélinde*, a play by De Visé, is printed. The scene is in the shop of a seller of lace, where persons of quality meet, and attack the reputation of "Élomire"—that is, Molière. He steals from the Italian, the Spanish, from Furetière's *Francion*, "il lit tous les vieux bouquins," he insults the *noblesse*, he insults Christianity, and so forth.

November 17, 1663.—*Portrait du peintre* is printed—an attack on Molière by Boursault. This piece is a detailed criticism, by several persons, of *L'Ecole des femmes.* It is pronounced dull, vulgar, farcical, obscene and (what chiefly vexed Molière, who knew the danger of the accusation) impious. Perhaps the only biographical matter we gain from Boursault's play is the interesting fact that Molière was a tennis-player. On the 4th November 1663, Molière replied with *L'Impromptu de Versailles*, a witty and merciless attack on his critics, in which Boursault was mentioned by name. The actors of the Hôtel de Bourgogne were parodied on the stage, and their art was ridiculed.

The next scenes in this comedy of comedians were:—

November 30.—The *Panégyrique de l'école des femmes*, by Robinet.

December 7.—*Réponse à l'impromptu; ou la vengeance des marquis*, by De Visé.

January 19, 1664.—*L'Impromptu de l'hôtel de Condé.* It is a reply by a son of Montfleury.

March 17, 1664.—*La Guerre comique; ou défense de l'école des femmes.*

1664.—*Lettre sur les affaires du théâtre*, published in *Diversités galantes*, by the author of *Zélinde.*

In all those quarrels the influence of Corneille was opposed to Molière, while his cause was espoused by Boileau, a useful ally, when "les comédiens et les auteurs, depuis le cèdre [Corneille?] jusqu'à l'hysope, sont diablement animés contre lui" (*Impromptu de Versailles*, sc. v.).

Molière's next piece was *Le Mariage forcé* (Feb. 15, 1664), a farce with a ballet. The comic character of the reluctant bridegroom excites contemptuous pity, as well as laughter. From the end of April till the 22nd of May the troupe was at Versailles, acting among the picturesque pleasures of that great festival of the king's. The *Princesse d'Élide* was acted for the first time, and the three first acts of *Tartuffe* were given. Molière's natural hatred of hypocrisy had not been diminished by the charges of blasphemy which were showered on him after the *École des femmes.* *Tartuffe* made enemies everywhere. Jansenists and Jesuits, like the two marquesses in *L'Impromptu de Versailles*, each thought the others were aimed at. Five years passed before Molière got permission to play the whole piece in public. In the interval it was acted before Madame, Condé, the legate, and was frequently read by Molière in private houses. The *Gazette* of the 17th of May 1664 (a paper hostile to Molière) says that the king thought the piece inimical to religion. Louis was not at that time on good terms with the *dévots*, whom his amours scandalized; but, not impossibly, the queen mother (then suffering from her fatal malady) disliked the play. A most violent attack on Molière, "that demon clad in human flesh," was written by one Pierre Roullé (*Le Roy glorieux au monde*, Paris, 1664). This fierce pamphlet was suppressed, but the king's own copy, in red morocco with the royal arms, remains to testify to the bigotry of the author, who was curé of Saint Barthélemy. According to Roullé, Molière deserved to be sent through earthly to eternal fires. The play was prohibited, as we have seen, but in August 1665 the king adopted Molière's troupe as his servants, and gave them the title of "troupe du roy." This, however, did not cause Molière to relax his efforts to obtain permission for *Tartuffe* (or *Tartufe*, or *Tartufle*, as it was variously spelled), and his perseverance was at length successful. That his thoughts were busy with contemporary hypocrisy is proved by certain scenes in one of his greatest pieces, the *Festin de Pierre*, or *Don Juan* (Feb. 15, 1665). The legend of *Don Juan* was familiar already on the Spanish, Italian and French stages. Molière made it a new thing: terrible and romantic in its portrait of *un grand seigneur mauvais homme*, modern in its suggested substitution of *la humanité* for religion, comic, even among his comedies, by the mirthful character of Sganarelle. The piece filled the theatre, but was stopped, probably by authority, after Easter. It was not printed by Molière, and even in 1682 the publication of the full text was not permitted. Happily the copy of De la Regnie, the chief of the police, escaped obliterations, and gave us the full scene of Don Juan and the Beggar. The piece provoked a virulent criticism (*Observations sur le festin de Pierre*, 1665). It is allowed that Molière has some farcical talent, and is not unskilled as a plagiarist, but he "attacks the interests of Heaven," "keeps a school of infidelity," "insults the king," "corrupts virtue," "offends the queen-mother" and so forth. Two replies were published, one of which is by some critics believed to show traces of the hand of Molière. The king's reply, as has been shown, was to adopt Molière's company as his servants, and to pension them. *L'Amour médecin*, a light comedy, appeared on the 22nd of September 1665. In this piece Molière, for the second time, attacked physicians. In December there was a quarrel with Racine about his play of *Alexandre*, which he treacherously transferred to the Hôtel de Bourgogne. The 4th of June 1666 saw the first representation of that famous play, *Le Misanthrope* (*ou L'Atrabiliaire amoureux*, as the original second title ran). This piece, perhaps the masterpiece of Molière, was more successful with the critics, with the court, and with posterity than with the public. The rival comedians called it "a new style of comedy," and so it was. The eternal passions and sentiments of human nature, modified by the influence of the utmost refinement of civilization, were the matter of the piece. The school for scandal kept by Célimène, with its hasty judgments on all characters, gave the artist a wide canvas. The perpetual strife between the sensible optimism of a kindly man of the world (Philinte) and the *saeva indignatio* of a noble nature soured (Alceste) supplies the intellectual action. The humours of the joyously severe Célimène and of her court, especially of that deathless minor poet Oronte, supply the lighter comedy. Boileau, Lessing, Goethe have combined to give this piece the highest rank even among the comedies of Molière. As to the "keys" to the characters, and the guesses about the original from whom Alceste was drawn, they are as valueless as other contemporary tattle.

A briefer summary must be given of the remaining years of the life of Molière. The attractions of *Le Misanthrope* were reinforced (Aug. 6) by those of the *Médecin malgré lui*, an amusing farce founded on an old *fabliau*. In December the court and the comedians went to St Germain, where, among other diversions, the pieces called *Mélicerte*, *La Pastorale comique* (of which Molière is said to have destroyed the MS.) and the charming little piece *Le Sicilien* were performed. A cold and fatigue seem to have injured the health of Molière, and we now hear of the consumptive tendency which was cruelly ridiculed in *Élomire hypochondre*. Molière was doubtless obliged to see too much of the distracted or pedantic physicians of an age when medicine was the battlefield of tradition, superstition, and nascent chemical science. On the 17th of April 1667 Robinet, the rhyming gazetteer, says that the life of Molière was thought to be in danger. On the 10th of June, however, he played in *Le Sicilien* before the town. In the earlier months of 1667 Louis XIV. was with the army in Flanders. There were embassies sent from the comedy to the camp, and on the 5th of August it was apparent that Molière had overcome the royal scruples. *Tartuffe* was played, but Lamoignon stopped it after the first night. La Grange and La Torillière hastened to the camp, and got the king's promise that he would reconsider the matter on his return. Molière's next piece (Jan. 13, 1668) was *Amphitryon*, a free—a very free—adaptation from Plautus, who then seems to have engaged his attention; for not long afterwards he again borrowed from the ancient writer in *L'Avare*. There is a controversy as to whether *Amphitryon* was meant to ridicule M. de Montespan, the husband of the new mistress of Louis XIV. Michelet has a kind of romance based on this probably groundless hypothesis. The king still saw the piece occasionally, after he had purged himself and forsworn sack under Mme de Maintenon, and probably neither he nor that devout lady detected any personal references in the coarse and witty comedy. As usual, Molière was accused of plagiarizing, this time from Rotrou, who had also imitated Plautus. The next play was the immortal *George Dandin* (July 10), first played at a festival at Versailles. Probably the piece was a rapid palimpsest on the ground of one of his old farces, but the addition of these typical members of a county family, the De Sotenville, raises the work from farce to satiric comedy. The story is borrowed from Boccaccio, but is of unknown age, and always new—Adolphus Crosbie in *The Small House at Allington* being a kind of modern George Dandin. Though the sad fortunes of this peasant with social ambition do not fail to make us pity him somewhat, it is being too refined to regard *George Dandin* as a comedy with a concealed tragic intention. Molière must have been at work on *L'Avare* before *George Dandin* appeared, for the new comedy after Plautus was first acted on the 9th of September. There is a tradition that the piece almost failed; but, if unpopular in the first year of its production, it certainly gained favour before the death of its author. *M. de Pourceaugnac* (Sept. 17, 1669) was first acted at Chambord, for the amusement of the king. It is a rattling farce. The physicians, as usual, bore the brunt of Molière's raillery, some of which is still applicable. Earlier in 1669 (Feb. 5) *Tartuffe* was played at last, with extraordinary success. *Les Amants magnifiques*, a comedy-ballet, was acted first at St Germain (Feb. 10, 1670). The king might have been expected to dance in the ballet, but from Racine's *Britannicus* (Dec. 13, 1669) the majestical monarch learned that Nero was blamed for exhibitions of this kind, and he did not wish to out-Nero Nero. Astrology this time took the place of medicine as a butt, but the satire has become obsolete, except, perhaps, in Turkey, where astrology is still a power. The *Bourgeois gentilhomme*, too familiar to require analysis, was first played on the 23rd of October 1770. The lively *Fourberies de Scapin* "saw the footlights" (if footlights there were) on the 24th of May 1671, and on the 7th of May we read in La Grange, "les Repetitions de Spsyche ont commancé." La Grange says the theatre was newly decorated and fitted with machines. A "concert of twelve violins" was also provided, the company being resolute to have everything handsome about them. New singers were introduced, who did not refuse to sing unmasked on the stage. Quinault composed the words for the music, which was by Lulli; Molière and Pierre Corneille collaborated in the dialogue of this magnificent opera, the name of which (*Psyche*) La Grange eventually learned how to spell. The *Comtesse d'Escarbagnas* (Feb. 2, 1672) was another piece for the amusement of the court, and made part of an entertainment called *Le Ballet des ballets*. In this play, a study of provincial manners, Molière attacked the financiers of the time in the person of M. Harpin. The comedy has little importance compared with *Les Femmes savantes* (Feb. 11), a severer *Précieuses*, in which are satirized the vanity and affectation of sciolists, pedants and the women who admire them. The satire is never out of date, and finds its modern form in *Le Monde où l'on s'ennuie*, by M. Pailleron. On the 17th of February Madeleine Béjard died, and was buried at St Paul. She did not go long before her old friend or lover Molière. His *Mariage forcé*, founded, perhaps, on a famous anecdote of Gramont, was played on the 18th of July. On the 7th of August La Grange notes that Molière was indisposed, and there was no comedy. Molière's son died on the 11th of October. On the 22nd of November the preparations for the *Malade imaginaire* were begun. On the 10th of February 1673 the piece was acted for the first time. What occurred on the 17th of February we translate from the *Registre* of La Grange:—

"This same day, about ten o'clock at night, after the comedy, Monsieur de Molière died in his house, Rue de Richelieu. He had played the part of the said Malade, suffering much from cold and inflammation, which caused a violent cough. In the violence of the cough he burst a vessel in his body, and did not live more than half an hour or three-quarters after the bursting of the vessel. His body is buried at St Joseph's, parish of St Eustache. There is a gravestone raised about a foot above the ground."

Molière's funeral is thus described in a letter, said to be by an eyewitness, discovered by M. Benjamin Fillon:—

"Tuesday, 21st February, about nine in the evening, was buried Jean Baptiste Poquelin Molière, *tapissier valet de chambre*, and a famous actor. There was no procession, except three ecclesiastics; four priests bore the body in a wooden bier covered with a pall, six children in blue carried candles in silver holders, and there were lackeys with burning torches of wax. The body . . . was taken to St Joseph's churchyard, and buried at the foot of the cross. There was a great crowd, and some twelve hundred livres were distributed among the poor. The archbishop had given orders that Molière should be interred without any ceremony, and had even forbidden the clergy of the diocese to do any service for him. Nevertheless a number of masses were commanded to be said for the deceased."

When an attempt was made to exhume the body of Molière in 1792, the wrong tomb appears to have been opened. Unknown is the grave of Molière.

Molière, according to Mlle Poisson, who had seen him in her extreme youth, was "neither too stout nor too thin, tall rather than short; he had a noble carriage, a good leg, walked slowly, and had a very serious expression. His nose was thick, his mouth large with thick lips, his complexion brown, his eyebrows black and strongly marked, and it was his way of moving these that gave him his comic expression on the stage." "His eyes seemed to search the deeps of men's hearts," says the author of *Zélinde*. The inventories printed by M. Soulié prove that Molière was fond of rich dress, splendid furniture, and old books. The charm of his conversation is attested by the names of his friends, who were all the wits of the age, and the greater their genius the greater their love of Molière. As an actor, friends and enemies agreed in recognizing him as most successful in comedy. His ideas of tragic declamation were in advance of his time, for he set his face against the prevalent habit of ranting. His private character was remarkable for gentleness, probity, generosity and delicacy, qualities attested not only by anecdotes but by the evidence of documents. He is probably the greatest of all comic writers within the limits of social and refined, as distinguished from romantic, comedy like that of Shakespeare, and political comedy like that of Aristophanes. He has the humour which is but a sense of the true value of life, and now takes the form of the most vivacious wit and the keenest observation, now of melancholy and pity and wonder at the fortunes of mortal men. In the literature of France his is the greatest name, and in the literature of the modern drama the greatest after that of Shakespeare. Besides his contemplative genius he possessed an unerring knowledge of the theatre, the knowledge of a great actor and a great manager, and hence his plays can never cease to hold the stage, and to charm, if possible, even more in the performance than in the reading.

The best biography of Molière on a level with the latest researches into his life is that in vol. x. of his works in *Grands écrivains de la France* (Eugène Despois and Paul Mesnard). The next best is probably that of M. Taschereau, prefixed to an edition of his works (*Œuvres complètes*, Paris, 1863). To this may be added Jules Loiseleur's *Les Points obscurs de la vie de Molière* (Paris, 1877). We have seen that M. Loiseleur is not always accurate, but he is laborious. For other books it is enough to recommend the excellent *Bibliographie moliéresque* of M. Paul Lacroix (1875), which is an all but faultless guide. The best edition of Molière's works for the purposes of the student is that published in *Les Grands écrivains de la France* (Hachette, Paris, 1874–1882). It contains reprints of many contemporary tracts, and, with the *Registre* of La Grange, and the *Collection moliéresque* of M. Lacroix, is the chief source of the facts stated in this notice, in cases where the rarity of documents has prevented the writer from studying them in the original texts. Another valuable authority is the *Recherches sur Molière et sur sa famille* of Ed. Soulié (1863). Lotheisen's *Molière, sein Leben und seine Werke* (Frankfurt, 1880), is a respectable German compilation. *Le Moliériste* (Tresse, Paris, ed. by M. Georges Monval) was a monthly serial, containing notes on Molière and his plays, by a number of contributors. The essays, biographies, plays and poems on Molière are extremely numerous. The best guide to these is the indispensable *Bibliographie* of M. Lacroix. (A. L.)

MOLINA, LUIS (1535–1600), Spanish Jesuit, was born at Cuenca in 1535. Having at the age of eighteen become a member of the Society of Jesus, he studied theology at Coimbra, and afterwards became professor in the university of Evora, Portugal. From this post he was called, at the end of twenty years, to the chair of moral theology in Madrid, where he died on the 12th of October 1600. Besides other works he wrote *Liberi arbitrii cum gratiae donis, divina praescientia, providentia, praedestinatione et reprobatione, concordia* (4to, Lisbon, 1588); a commentary on the first part of the *Summa* of Thomas Aquinas (2 vols., fol., Cuenca, 1593); and a treatise *De justitia et jure* (6 vols., 1593–1609). It is to the first of these that his fame is principally due. It was an attempt to reconcile, in words at least, the Augustinian doctrines of predestination and grace with the Semipelagianism which, as shown by the recent condemnation of Baius (*q.v.*), had become prevalent in the Roman Catholic Church. Assuming that man is free to perform or not to perform any act whatever, Molina maintains that this circumstance renders the grace of God neither unnecessary nor impossible: not impossible, for God never fails to bestow grace upon those who ask it with sincerity; and not unnecessary, for grace, although not an efficient, is still a sufficient cause of salvation. Nor, in Molina's view, does his doctrine of free-will exclude predestination. The omniscient God, by means of His "scientia media" (the phrase is Molina's invention, though the idea is also to be found in his older contemporary Fonseca), or power of knowing future contingent events, foresees how we shall employ our own free-will and treat His proffered grace, and upon this foreknowledge He can found His predestinating decrees. These doctrines, although in harmony with the prevailing feeling of the Roman Catholic Church of the period, and further recommended by their marked opposition to the teachings of Luther and Calvin, excited violent controversy in some quarters, especially on the part of the Dominicans, and at last rendered it necessary for the pope (Clement VIII.) to interfere. At first (1594) he simply enjoined silence on both parties so far as Spain was concerned; but ultimately, in 1598, he appointed the "Congregatio de auxiliis Gratiae" for the settlement of the dispute, which became more and more a party one. After holding very numerous sessions, the "congregation" was able to decide nothing, and in 1607 its meetings were suspended by Paul V., who in 1611 prohibited all further discussion of the question "de auxiliis," and studious efforts were made to control the publication even of commentaries on Aquinas. The Molinist subsequently passed into the Jansenist controversy (see Jansenism).

A full account of Molina's theology will be found in Schneeman's "Entstehung der thomistisch-molinistischen Controverse," published in the Appendices (Nos. 9, 13, 14) to the Jesuit periodical, *Stimmen aus Maria-Laach*. To the lay reader may be recommended Ernest Renan's article, "Les congrégations *de auxiliis*" in his *Nouvelles études d'histoire religieuse*.

MOLINE, a city of Rock Island county, Illinois, U.S.A., in the north-west part of the state, on the Mississippi river, adjoining the city of Rock Island and opposite the upper end of Rock Island. Pop. (1900), 17,248, of whom 5699 were foreign-born, principally Swedes and Belgians; (1910 census), 24,199. It is served by the Chicago, Burlington & Quincy, the Chicago, Milwaukee & St Paul, the Chicago, Rock Island & Pacific, and the Davenport, Rock Island & North-Western railways. A channel in the Mississippi river here, 250 ft. wide and 4 ft. deep at low water, projected in 1905, was completed in 1908; and in 1907 a lock was finished which affords a draught of 6 ft. and is a part of the 6 ft. channel improvement of Rock Island Rapids. The city has large and varied manufacturing industries; water-power is derived from a dam maintained by the Moline Water-Power Company; and there is a large electric-power plant. The most important industry is the manufacture of agricultural implements (particularly steel ploughs, which seem to have been made here first in the United States, and corn-planters). Among the other manufactures are boilers and gasolene engines, wagons and carriages, automobiles, and pianos and organs. The Chicago, Rock Island & Pacific railway has a 900-acre yard and machine shop east of the city limits, and there is a large U.S. arsenal on Rock Island. Moline was settled in 1832, laid out as a town in 1842, and was chartered as a city in 1855 and rechartered in 1872.

MOLINET, JEAN (1433–1507), French poet and chronicler, was born at Desvres (Pas de Calais). In 1475 he succeeded Georges Chastellain as historiographer of the house of Burgundy, and Margaret of Austria, governor of the Low Countries, made him her librarian. His continuation of Chastellain's chronicle, which covers the years from 1474 to 1504, remained unpublished until 1828 when it was edited (Paris, 5 vols.) by J. A. Buchon. It is far from possessing the historical value of his predecessor's work. A selection from his voluminous poetical works was published at Paris in 1531, *Les Faictz et Dictz de feu . . . Jehan Molinet. . . .* He also translated the *Roman de la rose* into prose (pr. Lyons, 1503). He became, in 1501, canon of the church of Notre-Dame at Valenciennes, where he died on the 23rd of August 1507. He is noteworthy as the head of the vicious Burgundian school of poetry known as the *rhétoriqueurs*, characterized by the excessive use of puns and of puerile metrical devices. His chief disciple was his nephew, Guillaume Crétin (d. 1525), ridiculed by Rabelais as Raminagrobis, and Jean Lemaire des Belges was his friend.

See A. Wauters in the *Biographie nationale de Belgique* (vol. xv., 1899).

MOLINIER, AUGUSTE (1851–1904), French historian, was born at Toulouse on the 30th of September 1851. He was a pupil at the École des Chartes, which he left in 1873, and also at the École des Hautes Études; and he obtained appointments in the public libraries at the Mazarine (1878), at Fontainebleau (1884), and at St Geneviève, of which he was nominated librarian in 1885. He was a good palaeographer and had a thorough knowledge of archives and manuscripts; and he soon won a first place among scholars of the history of medieval France. His thesis on leaving the École des Chartes was his *Catalogue des actes de Simon et d'Amauri de Montfort* (inserted in vol. xxxiv. of the *Bibliothèque de l'école*, an important contribution to the history of the Albigenses. This marked him out as a capable editor for the new edition of *L'histoire générale de Languedoc* by Dom Vaissète: he superintended the reprinting of the text, adding notes on the feudal administration of this province from 900 to 1250, on the government of Alphonso of Poitiers, brother of St Louis from 1226 to 1271, and on the historical geography of the province of Languedoc in the middle ages. He also wrote a *Bibliographie du Languedoc*, which was awarded a prize by the *Académie des inscriptions et belles-lettres*, but remained in manuscript. He also published several documents for the Société de l'Orient Latin (*Itinera hierosolymitana*, in collaboration with Ch. Kohler, 1885); for the Société de l'Histoire de France (*Chronique normande du xiv^{e} siècle*, assisted by his brother Émile, 1883); for the *Collection de textes relatifs à l'enseignement de l'histoire* (*Vie de Louis le Gros*, by Suger, 1887); for the *Collection des documents inédits* (*Correspondance administrative d'Alfonse de Poitiers*, 1894–1900); for the *Recueil des historiens de la France* (*Obituaires de la province de Sens* 1904, 1906), &c., and several volumes in the *Recueil des catalogues des bibliothèques publiques de France*. Applying to the French classics the rigorous method used with regard to the texts of the middle ages, he published the *Pensées* of Pascal, revised with the original manuscript (1887–1889), and the *Provinciales* (1891), edited with notes. In 1893 he was nominated professor at the École des Chartes, and gave a successful series of lectures which he published (*Manuel des sources de l'histoire de France au moyen âge*, 1902–1906). He also taught at the École des Hautes Études. He died on the 19th of May 1904, after a short illness, leaving in manuscript a criticism on the sources of the *Speculum historiale* of Vincent de Beauvais.

His elder brother, CHARLES (b. 1843), is also of some importance as an historian, particularly on the history of art and on the heresies of the middle ages. He was appointed professor of history at the university of Toulouse in 1886.

A younger brother, ÉMILE (1857–1906), became an assistant in the print-room at the Bibliothèque Nationale, and afterwards joined the staff at the Musée du Louvre, of which he eventually became keeper, retiring in 1902. He was a well-known connoisseur of art. He organized the famous Exposition Rétrospective held at the Petit Palais in 1900, and published a number of expert volumes on enamels, ceramics and furniture.

MOLINOS, MIGUEL DE (*c.* 1640–1697), Spanish divine, the chief apostle of the religious revival known as Quietism, was born about 1640 near Saragossa. He entered the priesthood and settled in Rome about 1670. There he became well known as a director of consciences, being on specially friendly terms with Cardinal Odescalchi, who in 1676 became Pope Innocent XI. In the previous year Molinos had published a volume, *Guida spirituale, che disinvolge l'anima e la conduce per l'interior camino all' acquisito della perfetta contemplazione e del ricco tesoro della pace interiore.* This was shortly followed by a brief *Trattato della cotidiana communione.* No breath of suspicion arose against Molinos until 1681, when the Jesuit preacher, Segneri, attacked his views, though without mentioning his name, in his *Concordia tra la fatica e la quiete nell' orazione.* The matter was referred to the Inquisition. It pronounced that the *Guida spirituale* was perfectly orthodox, and censured the intemperate zeal of Segneri. But the Jesuits set Father La Chaise to work on his royal penitent, Louis XIV., who prided himself on being a pillar of orthodoxy; but he was on very bad terms with Innocent XI., and soon yielded to the pleasure of discovering heresy in an intimate friend of the pope. Following on official representations by the French ambassador in Rome, who happened to be a cardinal, Molinos was arrested in May 1685. At first his friends were confident of an acquittal, but in the beginning of 1687 a number of his penitents of both sexes were examined by the Inquisition, and several were arrested. A report got abroad that Molinos had been convicted of moral enormities, as well as of heretical doctrines; and it was seen that he was doomed. On the 3rd of September 1687 he made public profession of his errors, and was sentenced to imprisonment for life. In the following November, Innocent signed a bull condemning sixty-eight propositions from the *Guida spirituale* and other unpublished writings of its author. At some date unknown in 1696 or 1697 Molinos died in prison.

Contemporary Protestants saw in the fate of Molinos nothing more than a persecution by the Jesuits of a wise and enlightened man, who had dared to withstand the petty ceremonialism of the Italian piety of the day. But Molinos was much more than the enlightened semi-Protestant that his English admirers took him to be; and his Quietism, had it been suffered to run its course would have swept aside beliefs and practices more important than the rosaries of nuns, though it is most unlikely that he realized the consequence of his own theories. Segneri and La Chaise were not so easily deceived. They were Jesuits; and Jesuitism is built up on the double assumption that God reveals Himself wholly and only through Jesus, and that Jesus reveals Himself wholly and only through the Church of Rome Luther had already broken through one link in this chain, when he taught the Protestant world to come directly to Jesus, without troubling about the Church; but Luther still assumed that God could only be reached through the intermediacy o Jesus. Molinos wished to find a royal road to God without any intermediaries at all. The Reformation maintained that the Church, so far from being a help, was a hindrance, to union with Jesus; whereas Molinos welcomed both Church and Jesus as helps to union with God, always provided that the believer treated both as means to an end beyond themselves. In other words, he held that there was a triple stage in piety. Beginners gave themselves wholly to the Church. At the second step came devotion to Jesus. At the third and highest stage both Church and Jesus were left behind as *deiformes, sed non Deus* and God remained alone.

But how could a finite being bring himself into direct relation with Infinity? Following very ancient precedents, Molinos fel back on those phenomena of our consciousness which seem least within our own power. The less sense of proprietorship we had in a thought or action—the less it was the fruit of our deliberate will—the more certain might we be that it was divinely inspired But what state of mind is most likely to be visited by these spontaneous illuminations? Plainly the state that Molinos calls the " soft and savoury sleep of nothingness," where the soul is content to fold its hands, and wait in dreamy musing till the message comes; meanwhile it will think, do, will as little as it can. For this reason disinterested love became the great hall-mark of Quietist sanctity. Why it is unfitted to be a test of sanctity in general has been explained at length by Bossuet in a remarkable *Instruction sur les états d'oraison*, published while the Quietist controversy was at its height. But, although Molinos's system did not long survive him, he had at least the double merit of courage and tenacity. Few writers have struggled so long and so hard to disengage the essence of religion from its transitionary embodiment in an historical creed.

The *Guida spirituale* was published in Italian in 1675, and ha been reprinted. An English translation appeared in 1688; it ha been re-edited by Mrs Arthur Lyttelton. French, Spanish and Latin translations have also appeared. For the history of it author see C. E. Scharling, *Michael de Molinos* (Ger. trans. from Danish; Gotha, 1855). H. Heppe, *Geschichte der quietistischen Mystik* (Berlin, 1875). On the whole subject of Quietism se H. Delacroix, *Études d'histoire et de psychologie du mysticism* (Paris, 1908). There is a brilliant, but very fanciful, account o Molinos and his doctrines in J. H. Shorthouse's romance, *Joh Inglesant.* (St C.)

MOLIQUE, WILHELM BERNHARDT (1802—1869), Germa violinist and composer, was born at Nuremberg on the 7th o October, 1802, and learnt the violin at Munich under Pietro

Rovelli. In 1826 he became music-director at Stuttgart. As a composer for the violin Molique was commonly compared with Spohr. He also wrote some charming songs. He died at Cannstadt in 1869.

MOLKO (1500–1532), a Marano kabbalist, who proclaimed the advent of the Messiah. He was associated with David Reubeni, who also made Messianic claims. Molko, after a chequered career, was condemned to death by the ecclesiastical court at Mantua. He was offered his life by the emperor Charles V. if he would return to Christianity, in which he had been educated. He refused, and died at the stake. (I. A.)

MÖLLENDORF, RICHARD JOACHIM HEINRICH VON (1724–1816), Prussian soldier, began his career as a page of Frederick the Great in 1740. The outbreak of the Silesian wars gave him his first opportunity of seeing active service, and the end of the second war saw him a captain. In the Seven Years' War his brilliant conduct at the churchyard of Leuthen (1757) and at Hochkirch won him his majority. In 1760 his exertions retrieved the almost lost battle of Torgau, and the last success of the great king was won by the brigades of Prince Wied and Möllendorf (now major-general) at the Burkersdorf heights. Seventeen years later, as lieutenant-general, he won at Brix one of the few successes of the Bavarian Succession (or "Potato") War. In the years of peace he occupied considerable posts, being made governor of Berlin in 1783. Promoted general of infantry in 1787, and general field marshal in 1793, he commanded the Prussian army on the Rhine in 1794. In the disastrous campaign of Jena (1806) Möllendorf played a considerable part, though he did not actually command a corps. He was present with the king at Auerstädt, falling into the hands of the French in the *débâcle* which followed. After his release he passed the remainder of his life in retirement. He died in 1816.

MOLLIEN, NICOLAS FRANÇOIS, COUNT (1758–1850), French financier, was born at Paris on the 28th of February 1758. The son of a merchant, he early showed ability, and entered the ministry of finance, where he rose rapidly; in 1784, at the time of the renewal of the arrangements with the farmers-general of the taxes, he was practically chief in that department and made terms advantageous to the national exchequer. Under Calonne he improved the returns from the farmers-general; and he was largely instrumental in bringing about the erection of the *octroi* walls of Paris in place of the insufficient wooden barriers. He, however, advocated an abolition of some of the restrictions on imports, as came about in the famous Anglo-French commercial treaty of 1786, to the conclusion of which he contributed in no small measure. The events of the French Revolution threatened at times to overwhelm Mollien. In 1794 he was brought before the revolutionary tribunal of Evreux as a suspect, and narrowly escaped the fate that befell many of the former farmers-general. He retired to England, where he observed the financial measures adopted at the crisis of 1796–1797. After the *coup d'état* of Brumaire (November 1799) he re-entered the ministry of finance, then under Gaudin, who entrusted to him important duties as director of the new *caisse d'amortissement*. Napoleon, hearing of his abilities, frequently consulted him on financial matters, and after the Proclamation of the Empire (May 1804) made him a councillor of state. The severe financial crisis of December 1805 to January 1806 served to reveal once more his sound sense. Napoleon, returning in haste not long after Austerlitz, dismissed Bargé-Marbois from the ministry of the treasury and confided to Mollien those important duties. He soon succeeded in freeing the treasury from the interference of great banking houses. In other respects, however, he did something towards curbing Napoleon's desire for a precise regulation of the money market. The conversations between them on this subject, as reported in Mollien's *Memoirs*, are of high interest, and show that the ministry had a far truer judgment on financial matters than the emperor, who often twitted him with being an *idéologue*. In 1808 Mollien was awarded the title of count. He soon came to see the impossibility of the measures termed collectively "the continental system"; but his warnings on that subject were of no avail. After the first abdication of the emperor (April 11, 1814), Mollien retired into private life, but took up his ministerial duties at the appeal of Napoleon during the Hundred Days (1815), after which he again retired. Louis XVIII. wished to bring him back to office, but he resisted these appeals. Nominated a peer in 1819, he took some part in connexion with the annual budgets. He lived to see the election of Louis Napoleon as president of the Second Republic, and died in April 1850, with the exception of Pasquier, the last surviving minister of Napoleon I.

Barante, *Études historiques et biographiques*; Salvandy, *Notice sur Mollien*; also M. M. C. Gaudin (duc de Gaëte), *Notice historique sur les finances de la France 1800–1814* (Paris, 1818). (J. HL. R.)

MOLLUSCA, one of the great "phyla," or sub-kingdoms, of the animal pedigree or kingdom. The shell-bearing forms belonging to this group which were known to Linnaeus were placed by him (in 1748) in the third order of his class Vermes under the name "Testacea," whilst the Echinoderms, Hydroids and Annelids, with the naked Mollusca, formed his second order termed "Zoophyta." Ten years later he replaced the name "Zoophyta" by "Mollusca," which was thus in the first instance applied, not to the Mollusca at present so termed, but to a group consisting chiefly of other organisms. Gradually, however, the term Mollusca became used to include those Mollusca formerly placed among the "Testacea," as well as the naked Mollusca.

It is important to observe that the term μαλακια, of which Mollusca is merely a latinized form, was used by Aristotle to indicate a group consisting of the cuttle-fishes only.

As now classified, the Mollusca consist of the following subdivisions:—

- Grade A.—Isopleura.
  - Class I.—Amphineura (see CHITON).
- Grade B.—Prorhipidoglossomorpha.
  - Class II.—Gastropoda (*q.v.*).
  - Class III.—Scaphopoda (*q.v.*).
  - Class IV.—Lamellibranchia (*q.v.*).
- Grade C.—Siphonopoda.
  - Class V.—Cephalopoda (*q.v.*).

History of Classification.—The definite erection of the Mollusca into the position of one of the great primary groups of the animal kingdom is due to George Cuvier (1788–1800), who largely occupied himself with the dissection of representatives of this type.[1]* An independent anatomical investigation of the Mollusca had been carried on by the remarkable Neapolitan naturalist Poli (1791), whose researches[2] were not published until after his death (1817), and were followed by the beautiful works of another Neapolitan zoologist, the illustrious Delle Chiaje.[3]

The *embranchement* or sub-kingdom Mollusca, as defined by Cuvier, included the following classes of shellfish: (1) the cuttles or poulps, under the name CEPHALOPODA; (2) the snails, whelks and slugs, both terrestrial and marine, under the name GASTROPODA; (3) the sea-butterflies or winged-snails, under the name PTEROPODA; (4) the clams, mussels and oysters, under the name ACEPHALA; (5) the lamp-shells, under the name BRACHIOPODA; (6) the sea-squirts or ascidians, under the name NUDA; and (7) the barnacles and sea-acorns, under the name CIRRHOPODA.

The main limitations of the sub-kingdom or phylum Mollusca, as laid down by Cuvier, and the chief divisions thus recognized within its limits by him, hold good to the present day. At the same time, three of the classes considered by him as Mollusca have been one by one removed from that association in consequence of improved knowledge, and one additional class, incorporated since his day with the Mollusca with general approval, has, after more than forty years, been again detached and assigned an independent position owing to newly acquired knowledge.

The first of Cuvier's classes to be removed from the Mollusca was that of the Cirrhopoda. Their affinities with the lower Crustacea were recognized by Cuvier and his contemporaries, but it was one of the brilliant discoveries of that remarkable and too-little-honoured naturalist, J. Vaughan Thompson, of Cork, which decided their position as Crustacea. The metamorphoses of the Cirrhopoda were described and figured by him in 1830 in a very complete manner, and the legitimate conclusion as to their affinities was formulated by him.[4] Thus it is to Thompson (1830), and not to Burmeister (1834), as erroneously stated by Keferstein, that the merit of this discovery belongs. The next class to be removed from Cuvier's

---

* These figures refer to the Bibliography at the end of the article.

Mollusca was that of the Nuda, better known as Tunicata. In 1866 the Russian embryologist Kowalewsky startled the zoological world with a minute account of the developmental changes of *Ascidia*, one of the Tunicata,[5] and it became evident that the affinities of that class were with the Vertebrata, whilst their structural agreements with Mollusca were only superficial. The last class which has been removed from the Cuvierian Mollusca is that of the Lamp-shells or Brachiopoda. The history of its dissociation is connected with that of the class, viz. the Polyzoa or Bryozoa, which has been both added to and again removed from the Mollusca between Cuvier's date and the present day. The name of J. Vaughan Thompson is again that which is primarily connected with the history of a Molluscan class. In 1830 he pointed out that among the numerous kinds of "polyps" at that time associated by naturalists with the Hydroids, there were many which had a peculiar and more elaborate type of organization, and for these he proposed the name Polyzoa. Subsequently[6] they were termed Bryozoa by Ehrenberg (1831).

Henri Milne-Edwards in 1844 demonstrated the affinities of the Polyzoa with the Molluscan class Brachiopoda, and proposed to associate the three classes Brachiopoda, Polyzoa and Tunicata in a large group "Molluscoidea," co-ordinate with the remaining classes of Cuvier's Mollusca, which formed a group retaining the name Mollusca. By subsequent writers the Polyzoa have in some cases been kept apart from the Mollusca and classed with the "Vermes"; whilst by others they have, together with the Brachiopoda, been regarded as true Mollusca. Increase of knowledge has now, however, established the conclusion that the agreement of structure supposed to obtain between Polyzoa and true Mollusca is delusive; and accordingly they, together with the Brachiopoda, were removed from the Molluscan phylum by Lankester in his article in the 9th edition of this work (on the which present article is based). Further details in regard to this, the last revolution in Molluscan classification, will be found in the article POLYZOA.

As thus purified by successive advances of embryological research, the Mollusca were reduced to the Cuvierian classes of Cephalopoda, Pteropoda, Gastropoda and Acephala. Certain modifications in the disposition of these classes are naturally enough rendered necessary by the vast accumulation of knowledge as to the anatomy and embryology of the forms comprised in them. Foremost among those who between 1840 and 1880 laboured in this field are the French zoologists Henri Milne-Edwards[9] and Lacaze Duthiers,[10] to the latter of whom we owe the most accurate dissections and beautiful illustrations of a number of different types. To Kölliker,[11] Gegenbaur,[12] and more recently Spenger,[13] amongst German anatomists, we are indebted for epoch-making researches of the same kind. In England, Owen's anatomy of the pearly nautilus,[14] Huxley's discussion of the general morphology of the Mollusca,[17] and Lankester's embryological investigations,[19] have aided in advancing our knowledge of the group. Two remarkable works of a systematic character dealing with the Mollusca deserve mention here—the *Manual of the Mollusca*, by Dr S. P. Woodward, a model of clear systematic exposition, and the exhaustive treatise on the Malacozoa or Weichthiere by Professor Keferstein of Göttingen, published as part of Bronn's *Klassen und Ordnungen des Thier-Reichs*.

The arrangement adopted by Ray Lankester in the 9th edition of the *Ency. Brit.* (art. "Mollusca"; 1883) was as follows: Of the four Cuvierian classes mentioned above, the Pteropoda were united with the Cephalopoda, on account of the apparent similarity of the cephalic tentacles in some of the former to the arms of the latter. An additional class was instituted for the reception of *Dentalium* and its few allies, and for this class Bronn's name Scaphopoda was used. The Chitons and their allies were placed under the Gastropoda, as a distinct branch called Isopleura, and for the Acephala de Blainville's name Lamellibranchia was substituted. The latter were regarded as forming a distinct branch, equivalent in rank to the other three classes together, the latter all possessing the radula which is wanting in Lamellibranchs.

Since the 9th edition of the *Ency. Brit.* was published important advances have been made in our knowledge of the Mollusca, as the result of researches largely due to the interest excited in the subject by Lankester's article. Attention has been especially directed to the investigation of the most primitive forms in each group, and accordingly we can now form much more definite conceptions of the phylogeny and evolution of the various classes. The most important and extensive contributions to this progress have been made by the Belgian zoologist, Dr Paul Pelseneer, who has made the Mollusca his special study.

The *Chitonidae* and the Aplacophora are now separated from the Gastropoda and raised to the rank of a distinct class, under the name of Amphineura. On the other hand, Boas and Pelseneer have shown that the Pteropoda have nothing to do with the Cephalopoda, but are Gastropoda modified for a pelagic life; they are therefore now united with the Gastropoda. The Lamellibranchia are no longer regarded as a distinct branch in contrast to the remaining Mollusca; according to Pelseneer they are allied to the Gastropoda and Scaphopoda, all three classes being derived from a common hypothetical ancestor, called *Prorhipidoglossum*. These three classes have therefore been united by Grobben into one branch or grade, the Prorhipidoglossomorpha.

General Characters of the Mollusca.—The forms comprised in the various groups, whilst exhibiting an extreme range of variety in shape, as may be seen on comparing an oyster, a cuttle-fish, and a sea-slug such as *Doris*; whilst adapted, some to life on dry land, others to the depths of the sea, others to rushing streams; whilst capable, some of swimming, others of burrowing, crawling or jumping, some, on the other hand, fixed and immobile; some amongst the most formidable of carnivores, others feeding on vegetable mud, or on the minutest of microscopic organisms—yet all agree in possessing in common a very considerable number of structural details which are not possessed in common by any other animals.

The structural features which the Mollusca do possess in common with other animals belonging to other great phyla of the animal kingdom are those characteristic of the Coelomata, one of the two great grades (the other and lower being that of the Coelentera) into which the higher animals, or Metazoa as distinguished from the Protozoa, are divided. The Metazoa all commence their individual existence as a single cell or plastid, which multiplies itself by transverse division. Unlike the cells of Protozoa, these embryonic cells of the Metazoa do not remain each like its neighbour and capable of independent life, but proceed to arrange themselves into two layers, taking the form of a sac. The cavity of the two-cell-layered sac or diblastula thus formed is the primitive gut or arch-enteron. In the Coelentera, whatever subsequent changes of shape the little sac may undergo as it grows up to be polyp or jelly-fish, the original arch-enteron remains as the one cavity pervading all regions of the body. In the Coelomata, on the other hand, there is another cavity, dividing the body-wall into two layers: an internal layer surrounding the gut, and an external layer. This cavity is excavated in a third mass of cells distinct from the cells lining the gut, forming the endoderm, and the cells covering the surface of the body, the ectoderm. This third mass of cells is the mesoderm. The Mollusca agree in being coelomate with the phyla Vertebrata, Platyhelmia (flat-worms), Echinoderma, Appendiculata (insects, ringed-worms, &c.), and others—in fact, with all the Metazoa except the sponges, corals, polyps, and medusae.

In common with all other Coelomata, the Mollusca are at one period of life possessed of a prostomium or region in front of the mouth, which is the essential portion of the "head," and is connected with the property of forward locomotion in a definite direction and the steady carriage of the body (as opposed to rotation of the body on its long axis). As a result, the Coelomata, and with them the Mollusca, present (in the first instance) the general condition of body known as bilateral symmetry; the dorsal is differentiated from the ventral surface, whilst a right and a left side similar to, or rather the complements of, one another are permanently established. In common with all other Coelomata, the Mollusca have the mouth and first part of the alimentary canal which leads into the met-enteron formed by a special invagination of the outer layer of the primitive body-wall, not to be confounded with that which often, but not always, accompanies the antecedent formation of the arch-enteron; this invagination is termed the stomodaeum. Similarly an anal aperture is formed in connexion with a special invagination which meets the hinder part of the met-enteron, and is termed the proctodaeum.

The coelom is primarily and essentially the generative cavity: the reproductive cells arise from its walls, *i.e.* from the coelomic epithelium. True nephridia do not primarily open into the coelom, as was formerly taught, but are intra-cellular ducts in the mesoderm. Such organs are absent in Mollusca in the adult state, but a pair of nephridia usually occurs in the larva. The coelom opens to the exterior by ducts which are primarily genital ducts by which the ova or sperms are discharged. These ducts, however, as well as the coelomic epithelium, may assume excretory functions. In Mollusca the coelom is reduced and consists of two parts, the pericardial cavity which surrounds the heart, and the cavity of the gonads or generative organs. There is usually one pair of coelomic ducts leading from the pericardium to the exterior, and these are the excretory organs or kidneys, formerly known as the organs of Bojanus. The walls of the pericardium are also excretory in parts, these parts forming the pericardial glands. In the majority of Mollusca the gonads are provided with a pair of ducts of their own. There are thus two pairs of coelomic ducts. This fact gives rise to the question whether the Mollusca are to be regarded as primitively segmented animals or not. In animals which exhibit typical segmentation or metamerism, such as segmented worms (Chaetopoda), each segment or metamere possesses its own coelomic cavity, a pair of coelomic ducts, and a pair of nephridia. The structure of the Mollusca in the greater number of cases agrees with the hypothesis that the primitive form was unsegmented, and therefore had but one pair of coelomic ducts and one pair of nephridia. In existing forms the latter disappear in the adult. In the most primitive forms of several classes there are no distinct genital ducts, the gonads when mature discharging into or through the kidneys. Among the Gastropoda, in the Aspidobranchia, there is no genital duct, and the gonad opens into the right kidney; in the more modified forms the left kidney alone is functional, the right has been converted into the genital duct. Among the Lamellibranchia again the kidneys serve as genital ducts in the Protobranchia and some Filibranchia. In the higher forms the opening of the gonad is shifted more and more towards the external aperture of each kidney until finally it is situated on the external surface, and thus the gonad secondarily acquires an independent aperture. In the Scaphopoda there is no distinct genital duct, the relations are as in Aspidobranchia. Among the Amphineura we find one pair of coelomic ducts in the Aplacophora, two pairs in the Chitons. In the former the genital coelom and the pericardial coelom are continuous and the reproductive cells escape by the renal ducts. In the Chitons or Polyplacophora, on the other hand, the two cavities are separate, and there are independent genital ducts. It is possible therefore to regard the latter condition as secondary, and to conclude that the separate genital ducts have been derived from the original single pair of coelomic ducts, as in Lamellibranchs.

The Cephalopoda, however, do not harmonize so well with this view. The earliest forms of this class geologically are the Nautiloidea. Assuming that these ancestral forms resembled the existing *Nautilus* in their internal anatomy, they had two pairs of renal ducts and one pair of genital ducts, which would apparently indicate, not a single metamere or unsegmented body, but three metameres. There are however only two pairs of branchiae. The Dibranchia, with only one pair of branchiae, one pair of renal organs, and one pair of genital ducts, are much more recent, not appearing till the end of the Secondary epoch, and therefore must be regarded as descended from the Tetrabranchia. The latter are represented in the Upper Cambrian formations, together with Lamellibranchia and Gastropoda, and there are no earlier Molluscan fossils than these. Palaeontology therefore throws no light on the question whether the metameric or the unsegmented Mollusca were the earlier. The development of the Cephalopoda affords at present no better evidence that the metamerism is secondary. That of *Nautilus*, which would be most important in this inquiry, is unfortunately still unknown. In the Dibranchia true nephridia have not been detected in the embryo, nor has it been shown that the genital ducts are derived from the renal tubes. On the other hand, there is no evidence that the forms which show no metamerism, such as the Gastropoda, are descended from metameric ancestors. On the whole, then, the most probable conclusion is that the original ancestral form of the Mollusca was unsegmented, possessed one pair of true nephridia, and one pair of coelomic ducts whose function was to conduct the generative products to the exterior. The chief types of Mollusca were already differentiated at the beginning of the geological record, and the metamerism which occurs in the Cephalopoda has been evolved within the limits of that class.

External Characters.—The characteristic organs of Mollusca are the mantle and shell, the foot, the ctenidia and the radula, of which all but the last are external. The original form was bilaterally symmetrical, and this symmetry is retained in all the classes except the Gastropoda. At the anterior end the head is differentiated; it bears the sense-organs, and contains the muscular pharynx within which is the radular apparatus. The rest of the body consists of the foot ventrally and the visceral mass dorsally. The foot is a muscular mass without cuticle or skeleton, excepting certain cuticular structures such as the byssus of Lamellibranchs and the operculum of Gastropods, which do not aid in locomotion. The foot is usually the only organ of locomotion. It corresponds to the ventral part of the body-wall in other animals. The muscular tissue of the dorsal body-wall is much reduced and the integument here is thin and soft. The external epithelium of the dorsal region secretes the shell. Between the edge of the shell and the foot there is a groove or cavity, chiefly developed laterally and posteriorly. The dorsal border of this groove is extended outwards and downwards as a fold of the integument. There is some confusion of terms here: some writers call the free fold the mantle or pallium, and this is the proper use of the term; but others apply the term to the whole of the dorsal integument, including both the projecting fold and the part covering the viscera. The shell extends to the edge of the mantle-fold, and the cavity between the mantle and the side of the body is the pallial chamber. This chamber serves two purposes: it is primarily

the respiratory cavity containing the gills, but it also serves to enclose the body so that the latter is surrounded by the shell, from which the head and foot can be protruded at the will of the animal.

The shell consists of an organic basis the substance of which is called conchiolin, impregnated with carbonate of lime, with a small proportion, 1–2 %, of phosphate of lime. On the outside of the shell is a non-calcified layer of conchiolin called the periostracum, secreted by the thickened edge of the mantle. The zone of the external surface of the mantle within the edge secretes a layer formed of prisms of calcite; the rest of the epithelium from this zone to the apex secretes the inner layer of the shell, composed of successive laminae; this is the nacreous layer, and in certain species has a commercial value as nacre or mother-of-pearl. Thus the growth of the shell in extent is due to additions to the prismatic layer at the edge, its growth in thickness to new layers of nacre deposited on its inner surface. In many cases in various classes the mantle is reflected over the edges of the shell, so as to cover more or less completely its outer surface. When this covering is complete the shell is contained in a closed sac and is said to be "internal," but the sac is lined by ectoderm and the shell is always morphologically external. In one or two cases the epithelium of the foot secretes a calcified shell, which is either free as in *Argonauta* or adherent as in *Hipponyx*.

The ctenidia (fig. 1) are the branchial organs of the Mollusca. In the primitive condition there is one on each side in the mantle cavity, towards the posterior end of the body. Each is an outgrowth of the body-wall at the side of the body, and consists of an axis containing two main vessels, an afferent and efferent, and bearing on either side a series of transverse plates whose blood-sinuses communicate with the vessels of the axis. The afferent vessel of the ctenidium receives blood from the vena cava or principal blood-sinus of the body, the efferent vessel opens into the auricle of its own side. Near the base of the ctenidium is a patch of sensory epithelium innervated from the branchial nerve, forming a sense-organ called the osphradium, whose function is to test the water entering the branchial cavity. The branchial current is maintained by the cilia which cover the surface of the ctenidia, except in Cephalopoda, in which cilia are absent and the current is due to muscular action. Thus in the primitive mollusc the mantle-cavity contains a symmetrical group of structures at the posterior end of the body, and this group of structures is called the pallial complex. It consists of the anus in the middle, a renal organ and renal aperture on each side of this, and a ctenidium outside or anterior to the renal organ, an osphradium being situated at the base of the ctenidium.

Internal Anatomy: Digestive Tube.—In primitive Mollusca the mouth and anus are the two extremities of the body, but the anus may be brought to an anterior position by a ventral flexure, complicated in Gastropoda by a lateral torsion. The alimentary tube consists of three regions: firstly, the anterior buccal mass with the oesophagus, of ectodermic origin, and therefore bearing cuticular structures, namely the jaws and radula; secondly, the mid-gut, of endodermic origin and including the stomach and liver; and, thirdly, the hind-gut or intestine. The radula consists of a chitinous band bearing teeth, secreted by a ventral caecum of the pharnyx and moved by an apparatus of cartilage and muscles. It was present in the ancestral mollusc, occurs in nearly all archaic types, and is only absent in the most specialized forms, in which it has evidently been lost; these forms are certain Neomeniomorpha, all the Lamellibranchia, various degenerate Gastropoda, and the *Cirrhoteuthidae* among Cephalopods. The teeth are secreted by a small number of cells at the closed end of the caecum, the basal membrane by a transverse row of cells in front of these. The teeth are disposed in transverse rows, and in each row they are arranged symmetrically on either side of a central tooth. In Polyplacophora there are eight on each side (8.I.8); in Scaphopoda two on each side (2.I.2); in almost all Cephalopoda three on each side (3.I.3); in Gastropoda the number varies very much in different subdivisions. Beneath the anterior parts of the radula where it emerges from the caecum are a pair of cartilages, and attached to these a number of special muscles by which the radula is moved backwards and forwards to act as a rasp. The secretion of the radula at the closed end of the caecum is continuous, so that it is constantly growing forward as fast as its exposed anterior portion is worn away by use, just as a finger-nail is pushed forward by constant growth at its posterior end, and is worn away or has to be cut short from time to time at its outer end.

Circulation.—The system of blood-vessels is entirely separate from the coelomic cavities. It consists of arteries, veins and sinuses, but ramified capillaries are usually absent except in the integuments of Cephalopods. The arteries and veins have proper endothelial walls; they pass abruptly into the sinuses and in some cases communication is effected by orifices in the walls of the vessels, as for example in the vena cava of *Nautilus*. The heart is situated in the pericardium on the dorsal side of the intestine and at the posterior end of the animal. The pericardium never contains blood, as is well shown in those forms which have red corpuscles in their blood; these corpuscles are never found in the pericardium.

The heart receives blood from the gills and mantle, and pumps it through arteries to the body. It consists of a median ventricle with muscular walls and a cavity traversed by muscular strands. On either side of the ventricle, in the primitive condition, is a thin-walled auricle, opening into the ventricle by a valved opening. Each auricle forms the terminal enlargement of the efferent vein of the ctenidium of its own side. In *Nautilus* two pairs of auricles are present, corresponding with the two pairs of ctenidia. In the primitive form a single anterior aorta is given off from the ventricle, the two together representing the dorsal blood-vessel of Chaetopods. In more specialized forms a posterior aorta passes backwards from the ventricle, as in Gastropods and the majority of Lamellibranchs. The ramifications of the arteries convey the blood to all parts of the body, and it finally reaches the venous sinuses, the chief of which are the pedal, the pallial and the median-ventral. The last is between the pericardium and the foot; from it the blood passes through the renal organs to the ctenidia. Some blood, however, enters the auricles directly from the mantle, without passing through the ctenidia. In the majority of Gastropoda one gill and one auricle are lost.

The blood is usually a colourless liquid containing amoeboid cells and sometimes other corpuscles called haematids. It may be coloured blue by haemocyanin, a respiratory compound containing copper. In a few forms the blood contains haemoglobin, either in solution or in haematids (red blood-corpuscles). In the Gastropoda the muscular tissue of the buccal mass is coloured red by haemoglobin.

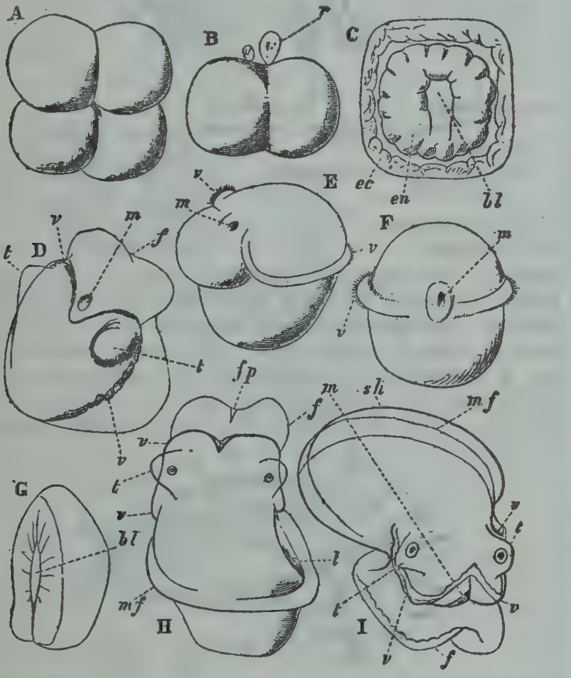
Nervous System.—The central nervous system may be described as consisting of a collar surrounding the oesophagus, and two pairs of cords arising from the collar and passing backwards. The two pairs of cords arise from the same point of the collar. The ventral cords are the pedal, the dorso-lateral, the pleural, the former innervating the foot; the latter the mantle. The dorsal half of the collar is the cerebral commissure, the ventral the labial commissure. The pedal cords are connected by commissures, and the pedal and pleural of each side are similarly connected. The pallial cords are united to one another posteriorly, dorsal to the rectum. This is the condition of the nervous system found in *Chiton* and the other Amphineura, but may not be in all respects the ancestral condition. Generally the system is differentiated into ganglia connected by nerve-cords consisting of nerve-fibres only. At the point of the collar whence the nerve-cords arise are the cerebral ganglia; from these one pair of connectives passes to a pair of pedal ganglia, and another pair of connectives to a pair of pleural ganglia. Pedal and pleural on each side are connected by a pleuro-pedal connective Each pleural ganglion gives off a long nerve which supplies the viscera, and the two unite posteriorly below the intestine. There are usually three small ganglia on the course of this visceral commissure, namely, the right and left visceral ganglia and the abdominal. The perioesophageal nerve-ring of Chaetopoda and Arthropoda is represented, not by the collar first mentioned in the above description, but by the commissures connecting the cerebral and pedal ganglia. The labial commissure supplies only the buccal mass and the oesophagus and stomach.

The special sense-organs are a pair of eyes on the head, a pair of otocysts or statocysts, and a pair of osphradia which have already been mentioned. In certain cases accessory eyes are also present, *e.g.* the pallial eyes of *Pecten* and other Lamellibranchs, and of Chitons. The otocysts are invaginations of the epithelium of the foot, but are innervated from the cerebral ganglia, and the same innervation has been proved in some cases for the osphradia.

Reproduction and Development.—Molluscs are usually of separate sexes, but sexual dimorphism is seldom highly developed. Hermaphroditism is secondary, and occurs in one sub-class of Gastropoda, in some Lamellibranchs, and in one sub-order of Amphineura. In Cephalopods and the majority of Gastropods copulation occurs. As a rule no parental care is exhibited, but incubation of the developing ova within some part of the parental body, or receptacles attached to the parent, occurs in some Lamellibranchs, some Gastropods, and in *Argonauta* among the Cephalopods. True viviparity, that is the development of the ova within the oviduct, is very rare, occurring only in one case among the Amphineura and in some aquatic and pulmonate Gastropoda.

The egg-cell of Mollusca is either free from food-material—a simple protoplasmic corpuscle—or charged with food-material to a greater or less extent. Those cases which appear to be most typical —*i.e.* which adhere to a procedure which was probably common at one time to all then existing Mollusca and has been departed from only in later and special lines of descent—show approximately the following history. By division of the egg-cell a mulberry-mass of embryonic-cells is formed (morula), which dilates, forming a one-cell-layered sac (blastula). By invagination one portion of this sphere becomes tucked into the other—as in the preparation of a woven night-cap for the head. The orifice of invagination (blastopore) narrows, and we now have a two-cell-layered sac—the gastrula. The invaginated layer is the enteric cell-layer or endoderm; the outer cell-layer is the dermic cell-layer or ectoderm. The cavity communicating with the blastopore and lined by the endoderm is the archenteron. The blastopore, together with the whole embryo, now elongates. The blastopore then closes along the middle portion of its extent, which corresponds with the later developed foot. At the same time the stomodaeum, or oral invagination, forms around the anterior remnant of the blastopore, and the proctodaeum, or anal invagination, forms around the posterior remnant of the blastopore. There are, however, variations in regard to the relation of the blastopore to the mouth and to the anus which are probably modifications of the original process described above.

In eggs which contain a larger quantity of food-yolk, the process by which the endoderm is enveloped by the ectoderm is somewhat different. Segmentation in these is very unequal, and results in the formation of small cells called micromeres and large cells called megameres, as in fig. 4. As the micromeres become more numerous they gradually envelop the megameres until the latter are completely enclosed. The gastrula is in these cases said to be formed by epibole. Between ectoderm and endoderm a third intermediate cell-layer is formed, which is called the mesoderm, and gives rise to the muscular and connective tissues to the vascular system, and to the excretory and generative organs. The mesoderm arises for the most part from the endoderm. When the segmentation is unequal one of the megameres gives rise by successive divisions to two primary mesoderm cells called mesomeres; these divide to form two masses of cells called mesoblastic bands. The coelom is formed as a cavity or cavities in the interior of these cell-masses. In some cases the coelom is formed as a single cavity, and renal and generative organs are formed from its walls. This is the primitive method, but in other cases the organs mentioned may be formed separately in the mesoderm. The renal organs are tubular outgrowths of the pericardial parts of the coelom; the reproductive cells are derived from cells lining the generative portion.



(After Lankester, 15.)

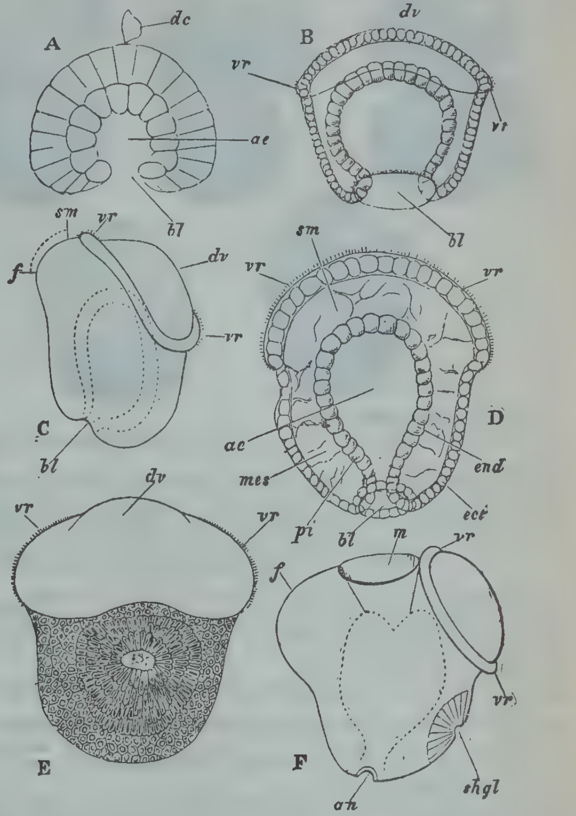
t, Tentacles.
fp, Pore in the foot (belonging to the pedal gland?).
mf, The mantle-flap or limbus pallialis.
sh, The shell.
l, The sub-pallial space, here destined to become the lung.

A, First four cells resulting from the cleavage of the original egg-cell.
B, Side-view of the same.
C, Diblastula stage showing the two cell-layers and the blastopore.
D, E, F, Trochosphere stage, D older than E or F.
G, Three-quarter view of a Diblastula, to show the orifice of invagination of the endoderm or blastopore, (*bl*).
H, I, Veliger stage later than D.

The external form of the embryo meanwhile passes through highly characteristic changes, which are on the whole fairly constant throughout the Mollusca. A circlet of cilia forms when the embryo is still nearly spherical in an equatorial position. As growth proceeds, one hemisphere remains relatively small, the other elongates and enlarges. Both mouth and anus are placed in the larger area; the smaller area is the prostomium simply; the ciliated band is therefore in front of the mouth. The larval form thus produced is known as the trochosphere. It exactly agrees with the larval form of many Chaetopod worms and other Coelomata. Most remarkable is its resemblance to the adult form of the Wheel animalcules, or Rotifera, which retain the prae-oral ciliated band as their chief organ of locomotion and prehension throughout life. So far the young mollusc has not reached a definitely molluscan stage of



(After Lankester, 17.)

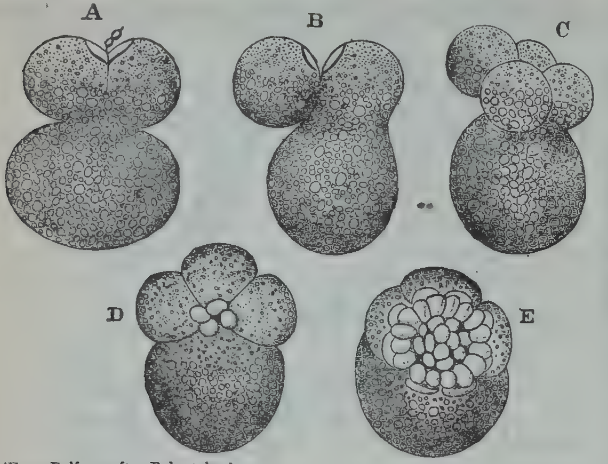
sm, Site of the as yet unformed mouth.
f, Foot.
mes, Rudiments of the skeletotrophic tissues.
pi, The pedicle of invagination, the future rectum.
shgl, The primitive shell-sac or shell-gland.
m, Mouth. *an*, anus.

A, Gastrula phase (optical section).
B, The Gastrula has become a Trochosphere by the development of the ciliated ring *vr* (optical section).
C, Side view of the Trochosphere with commencing formation of the foot.
D, Further advanced Trochosphere (optical section).
E, The Trochosphere passing to the Veliger stage, dorsal view showing the formation of the primitive shell-sac.
F, Side view of the same, showing foot, shell-sac (*shgl*), velum (*vr*), mouth and anus.

N.B.—In this development the blastopore is not elongated; it persists as the anus. The mouth and stomodaeum form independently of the blastopore.

development, being only in a condition common to it and other Coelomata. It now passes to the veliger phase, a definitely molluscan form, in which the disproportion between the area in front of the ciliated circlet and that behind it is very greatly increased, so that the former is now simply an emarginated region of the head fringed with cilia. It is termed the "velum," and is frequently drawn out into lobes and processes. As in the Rotifera, it serves the veliger larva as an organ of locomotion. The body of the veliger is characterized by the development of the visceral hump on one surface, and by that of the foot on the other. Growth is greater in the vertical dorso-ventral axis than in the longitudinal oro-anal axis; consequently the foot is relatively small and projects as a blunt process between mouth and anus, which are not widely distant from one another, whilst the antipedal area projects in the form of a great hump or dome. In the centre of this antipedal area there has appeared (often at a very early period) a gland-like depression or follicle of the integument. This is the primitive shell-sac discovered by Lankester in 1871, and shown by him to precede the development of the permanent shell in a variety of molluscan types. The shell-gland is bounded by a ridge of ectodermic cells. This ridge forms the edge of the shell-secreting epithelium, and therefore of the mantle, since the shell extends to the edge of the mantle. The shell-gland, as development proceeds, extends from its point of origin as an ectodermic thickening, which may be only slightly concave or may be deeply invaginated and then evaginated.



(From Balfour, after Bobretzky.)

FIG. 4.—Early Stages of division of the Fertilized Egg-cell in *Nassa mutabilis.*

- A, The egg-cell has divided into two spheres, of which the lower contains more food-material, whilst the upper is again incompletely divided into two smaller spheres. Resting on the dividing upper sphere are the eight-shaped "directive corpuscles," better called "praeseminal outcast cells or apoblasts," since they are the result of a cell-division which affects the egg-cell before it is impregnated, and are mere refuse, destined to disappear.
- B, One of the two smaller spheres is reunited to the larger sphere.
- C, The single small sphere has divided into two, and the reunited mass has divided into two, of which one is oblong and practically double, as in B.
- D, Each of the four segment-cells gives rise by division to a small pellucid cell.
- E, The cap of small cells has increased in number by repeated formation of pellucid cells in the same way, and by division of those first formed. The cap will spread over and enclose the four segment-cells.

In the larvae of several Gastropoda and Lamellibranchia occur excretory organs which have the characters of true nephridia. There is a single pair of these organs situated immediately behind the velum. They agree with primitive nephridia in being of ectodermic origin, in consisting of perforated cells in linear series, and in having no communication with the coelom. The inner end of each of these organs consists of a flame-cell, *i.e.* a cell with an internal cavity containing a vibrating filament or flagellum. They are best developed in the Pulmonata; in some cases they are very rudimentary and may be destitute of an external opening. They invariably disappear before the adult stage is reached, but their presence in the larva is evidence that the ancestral mollusc possessed a pair of true nephridia quite distinct from the coelomic excretory organs, which are so characteristic of existing forms in the adult condition.

The ctenidia, it will be observed, have not yet been mentioned, and they are indeed the last of the characteristic Molluscan organs to make their appearance. They arise as outgrowths of the sides of the body within the cavity formed by the development of the mantle. The veliger, as soon as its shell has attained some extent and begins to assume definite shape, is no longer of a form common to Mollusca generally, but acquires characters peculiar to the particular class to which its parents belong. For the later development therefore the articles on the several classes must be consulted.

Relations between the Classes.—From the preceding discussion an idea may be formed of the primitive characters of the Phylum Mollusca, and it is possible to construct a diagrammatic mollusc, as was first done by Lankester, which will possess these primitive features. The figure here given represents such a hypothetical form according to present views. We cannot assert that this was in all respects the condition of the common ancestor, as will be seen when we attempt to derive the various sub-types from it. In the Amphineura the nervous system, having no separate ganglia and no ventral visceral commissure, may be still more primitive. The metameric repetition of the shell-plates and of the ctenidia are probably special modifications, but it is difficult to explain the spicules of the dorsal integument except as a condition more primitive than the shell itself. The Prorhipidoglossomorpha are distinguished by the separation of the genital coelom from the pericardium, and by the long visceral commissure passing ventral to the intestine. The Lamellibranchia have markedly diverged from the original type by the adoption of filtration as a method of feeding. This has ed to the loss of the radula, and is accompanied by the division of the shell into two valves. The peculiarities of the Gastropoda are all due to the torsion of the shell and body. The Cephalopoda can be derived without much difficulty from the schematic Mollusc, if we assume that some metameric repetition of organs has occurred, as explained above in reference to the coelom. The foot has been developed into long processes which have extended in a circle round the mouth; all the ganglia, including the visceral, have been concentrated around the oesophagus.

Habits and Distribution.—More than 28,000 species of living Molluscs have been distinguished, of which more than half are Gastropods. They are essentially aquatic animals, and the majority live in the sea. Some, like many Cephalopods and the Pteropods, are pelagic or free-swimming; others creep or lie on the sea bottom. Some are littoral, living between tide-marks; others are found at very various depths, up to 2800 fathoms. A few species have invaded the fresh waters, while the pulmonate and terrestrial Gastropods are distributed over the whole surface of the land in all latitudes and to a height of 15,000 ft. As a rule Molluscs are free and more or less active, but many Lamellibranchs are sedentary, and a few of these and of Gastropods are permanently fixed to their habitat. Commensalism occurs in a few instances, but parasitism either external or internal is rare. The latter is confined to certain Gastropods which live in Echinoderms and are extremely degenerate in structure. Protective resemblance is exhibited by some Nudibranch Gastropods which have assumed the colour and appearance of their habitat.

MOLLUSCOIDA, a name long employed to denote a division of the animal kingdom which contained *Brachiopods* (*q.v.*), *Polyzoa* (*q.v.*), and *Tunicata* (*q.v.*), the members of the three groups having been supposed to resemble the *Mollusca*. As it is now known that these groups have no relation to molluscs, and very little to one another, the name Molluscoida has been abandoned.

MOLLY MAGUIRES, an Irish American secret society which maintained numerous branches in the anthracite coal regions of Pennsylvania, U.S.A., from 1854 to 1877, and perhaps later. The name was imported from Ireland, where it had been used to designate one of the Ribbon societies that devoted its energies to intimidating and maltreating process servers and the agents of landlords, and whose greatest activity was between 1835 and 1855. The Irish society of Molly Maguires seems to have been organized in 1843 in the barony of Farney, Co. Monaghan, to co-operate with the ribbonmen, and its membership seems to have been confined to the very lowest classes. The Molly Maguires of Pennsylvania consisted of similar classes of Irishmen, but there seems to have been no connexion between the two societies. Every member of the American organization was also a member of the Ancient Order of Hibernians, an association organized for benevolent purposes, and having branches throughout the United States and Great Britain. To the Ancient Order of Hibernians none might be admitted but persons of Irish birth or descent, who were Roman Catholics, and whose parents were Roman Catholics; but notwithstanding this requirement, the organization—being a secret society—was under the ban of the Catholic Church. At the head of each division or lodge there was a "body master," who communicated directly with a county delegate; the county delegates reported to the state delegate, and the state delegates to a national delegate. The supervision of the whole order was vested in a "Board of Erin," meeting quarterly in England, Ireland or Scotland, and at each meeting arranging a new code of signals and passwords, which were communicated to the national delegate in the United States by the steward of a transatlantic steamship, and thence were transmitted to the various subdivisions. In the mining districts of Pennsylvania the organization fell under the control of a lawless element, which created the inner order of "Molly Maguires," with the object, it appears, of intimidating the Welsh, English, and German miners, and of ridding the region of mine superintendents, bosses and police who should make themselves in any way objectionable to members of the order. Any member having a grievance might lay a formal complaint before his "body master," who thereupon conferred with the officers of the neighbouring divisions and secured members from a distance to make away with the offending person. Under this system the crimes in a given district were always committed by strangers rendering identification of the criminal difficult and escape easy. The society grew in strength during the Civil War, when the increased demand for coal caused an influx of miners, many of them lawless characters, into the coal-fields, and in 1862–1863 it opposed enlistments in the Federal Army and roughly treated some of the enlisting officers. After the war its activity was shown by an increasing number of assassinations, burnings and other outrages, until by 1875 it completely dominated the mining classes and forced a general strike in the coal regions. After repeated efforts to bring the criminals to justice had failed, Franklin B. Gowen (1836–1889), president of the Philadelphia and Reading Coal and Iron Company, sent James McParlan, an Irish Catholic and a Pinkerton detective (who some thirty years later attracted attention in the investigation of the assassination of Governor Steunenberg of Idaho), to the mining region in 1873; he joined the order, lived among the "Molly Maguires" for more than two years, and even became secretary of the Shenandoah division, one of the most notoriously criminal lodges of the order. The evidence he secured led to the arrest, conviction, and execution or imprisonment of a large number of members during the years 1876–1877, and subsequently the outrages ceased and the society was disbanded.

See F. P. Dewees, *The Molly Maguires* (Philadelphia, 1877); Allan Pinkerton, *The Molly Maguires and the Detectives* (New York, 1877); E. W. Lucy, *The Molly Maguires of Pennsylvania;* (London, n.d.); *The Commonwealth versus John Kehoe et al.* (Pottsville, Pa., 1878); and an article by J. F. Rhodes in *Amer. Hist. Review*, April, 1910.

MOLOCH, or Molech (in Hebrew, with the doubtful exception of 1 Kings xi. 7, always "*the* Molech"), the name or title of the divinity which the men of Judah in the last ages of the kingdom were wont to propitiate by the sacrifice of their own children. According to the Hebrew consonants it might simply be read "the king" (*mélek*), an appellation for the supreme deity of a Semitic state or tribe. The traditional pronunciation (Μολόχ), which goes back as far as the Septuagint version of Kings, probably means that the old form was perverted by giving it the vowels of *bōsheth* "shame," the contemptuous name for Baal (*q.v.*). In 1 Kings xi. 7 (see above) it is the name of the god of the Ammonites, elsewhere called Milcom or Malcam; but it appears from 2 Kings xxiii. 10, 13 that the worship of Milcom at the shrine set up by Solomon was distinct from Molech worship, and the text should probably therefore be emended to the longer form (so the Septuagint).

The phrase employed in speaking of these sacrifices is that of dedication—"to make one's son or daughter pass through (or by means of) fire to (the) Molech" (2 Kings xxiii. 10; but elsewhere without the words "through fire" Lev. xviii. 21); and it appears from Jer. vii. 31, xix. 5; Ezek. xvi. 20 seq., that this phrase denotes a human holocaust,[1] and not, as sometimes has been thought, a mere consecration to Molech by passing through or between fires, as in the Roman *Palilia* and similar rites elsewhere (on which see Frazer, *Golden Bough*, 2nd ed., ii. 40 sqq., iii. 237 sqq.). Human sacrifice was common in Semitic heathenism, and at least the idea of such sacrifices was not unknown to Israel from early times (see Isaac; Jephthah).[2] We learn from 2 Kings iii. 27 that the piacular sacrifice of his son and heir was the last offering which the king of Moab made to deliver his country. Even the Hebrew historian ascribes to this act the effect of rousing divine indignation against the invading host of Israel; it would not, therefore, be surprising if under the miseries brought on Palestine by the westward march of the Assyrian power, the idea of the sacrifice of one's own son, as the most powerful of atoning rites, should have taken hold of those kings of Judah (Ahaz and Manasseh, 2 Kings xvi. 3 xxi. 6) who were otherwise prone, in their hopelessness of help from the old religion (Isa. vii. 12), to seek to strange peoples and their rites. Ahaz's sacrifice of his son (which indeed rests on a somewhat late authority) was apparently an isolated act of despair, since human sacrifices are not among the corruptions of the popular religion spoken of by Isaiah and Micah. In the 7th century, however, when the old worship had sustained rude shocks, and all religion was transformed into servile fear (Mic. vi. 1 seq.), the example of Manasseh did not stand alone, and Jeremiah and Ezekiel made frequent and indignant reference to the "high places" for the sacrifice of children by their parents which rose beneath the very walls of the temple from the gloomy ravine of Hinnom or Tophet.[3] (Jer. vii. 31, xix., xxxii. 35; Ezek. xvi. 18 sqq., xxiii. 37). The children apparently were not burned alive; they were slain and burned like any other holocaust (Ezek. *loc. cit.*; Isa. lvii. 5), their blood was shed at the sanctuary (Jer. xix. 4; Ps. cvi. 38). Thus the late Rabbinical picture of the calf-headed brazen image of Molech within which children were burned alive is pure fable, and with it falls the favourite comparison between Molech and the Carthaginian idol from whose brazen arms children were rolled into an abyss of fire, and whom Diodorus (xix. 14) naturally identifies with the child-eater Kronos, thus leading many moderns to make Molech the planet Saturn.

It is with these sacrifices that the name of "the Molech" is always connected; sometimes "the Baal" (lord) appears as a synonym. At the same time, the horrid ritual was so closely associated with Yahweh worship (Ezek. xxiii. 39) that Jeremiah more than once finds it necessary to protest that it is not of Yahweh's institution (vii. 31, xix. 5). So too it is the idea of sacrificing the firstborn to Yahweh that is discussed and rejected in Micah vi. It is indeed plain that such a sacrifice—for we have here to do, not with human victims in general, but with the sacrifice of the dearest earthly thing—could only be paid to the supreme deity; and Manasseh and his people never ceased to acknowledge Yahweh as the God of Israel. Thus the way in which Jeremiah (Jer. xix. 5) and the legislation of Leviticus (xviii. 21, xx. 2–5) and the author of Kings, seem to mark out the Molech or Baal as a false god, distinct from Yahweh, is precisely parallel to the way in which Hosea speaks of the golden calves or Baalim. In each case the people thought themselves to be worshipping Yahweh under the title of Molech or Baal; but the prophet refuses to admit that this is so, because the worship itself is an apostasy to heathenism. Note, also the attitude of Ezekiel in xx. 25 seq., 31, references which cannot be explained away.

Although the motive came from within, the *form* taken by the cult has appeared to many to be of non-Israelite origin. Babylonia and Assyria, however, seem to be out of the question: *malik*, "arbiter, decider," is there an epithet of various gods, and as an appellative means "prince" and not king; further, little vidence for the prevalence of human sacrifice has as yet been ound in those lands (A. Jeremias, *Das Alte Test. im Lichte d. alten rients*, 2nd ed., p. 454). Among the Canaanite branch, the ing-god is more prominent, and apart from the Ammonite ariant Milcom, numerous names compounded with Milk- are ound on Phoenician inscriptions and among western Semites entioned in cuneiform literature (H. Zimmern, *Keilinschr. u. as Alte Test.*, 3rd ed. pp. 470 sqq.). It is true that child-crifice in connexion with fire prevailed among the Phoenicians, nd, according to the Greeks, the deity honoured with these risly rites was Kronos (identified with the Phoenician El, God"). On the other hand, the seat of the cult appears to ave been at Jerusalem, and the period during which it flourished oes not favour any strong Phoenician influence. Again, the rm of the word Tophet and Ahaz's association with Damascus ight point to an Aramaean origin for the cult; but it would ot be safe to support this view by the statements and names 2 Kings xvii. 31. On the whole, the biblical tradition that e Molech-cult was Canaanite and indigenous (Deut. xii. 29 sqq., viii. 9 seq.) holds the ground. There was a tendency in time misfortune to revert to earlier rites (illustrated in some ncient mourning customs), and it may have been some old isused practice revived under the pressure of national distress.

---

[1] In 2 Chron. xxviii. 3 (parallel to 2 Kings xvi. 3) a single letter is transposed in the phrase, changing the sense from "caused to pass through the fire" to "caused to burn with fire." Geiger (*Urschrift und Uebersetzung*, p. 305) very unnecessarily supposed that this was everywhere the original reading, and that it had been changed to soften the enormity ascribed to the ancient Hebrews. The phrase "to give one's seed to Molech" (Lev. xx. 2 seq.), and the fact that these victims were (like other sacrifices) regarded as food for the deity (Ezek. xvi. 20) explain and justify the common reading.

[2] In Hos. xiii. 2, the interpretation "they that sacrifice men" is improbable, and 2 Kings xvii. 17 and Lev. xviii., xx. are of too late date by themselves to prove the immolation of children to Moloch in old Israel. The "ban" (חרם), which was a religious execution of criminals or enemies, was common to Israel with its heathen neighbours (cf. the inscription of Mesha), but lacked the distinctive character of a sacrifice in which the victim is the food of the deity conveyed to him through fire.

[3] The etymology of the word Tophet is obscure; it is possibly o Aramaic origin and means "fire-place," cf. *tophteh*, "pyre," (Isa. xxx 33). The vocalization is artificial, the Masoretes having given i the vowel-points of *bōsheth*. See W. R. Smith, *Religion of the Semites* 2nd ed., 377.

MOLSHEIM, a town of Germany, in the imperial province of lsace-Lorraine at the foot of the Vosges, on the Breusch and the junction of railways to Zabern and Strassburg. Pop. 905), 3164. It contains a beautiful Roman Catholic and a rotestant church, a handsome new town-hall and an agricultural hool. Its industries embrace the manufacture of iron and eel goods, tanning and organ-building. There is also some ade in wine. Molsheim was known in the 9th century as olleshem, and formerly was the seat of a famous Jesuit college, hich in 1702 was removed to Strassburg and united with the niversity of that city.

MOLTKE, ADAM GOTTLOB, COUNT (1710–1792), Danish ourtier, was born on the 10th of November 1710, at Riesenhof Mecklenburg. Though of German origin, many of the oltkes were at this time in the Danish service, which was onsidered a more important and promising opening for the oung north German noblemen than the service of any of the ative principalities; and through one of his uncles, young oltke became a page at the Danish court, in which capacity e formed a life-long friendship with the crown prince Frederick, fterwards Frederick V. He never had any opportunity of nriching his mind by travel or study, but he was remarkable or a strongly religious temperament and seems for some time have been connected with the Moravians. Immediately fter his accession, Frederick V. made him hofmarskal (court arshal), and overwhelmed him with marks of favour, making im a privy councillor and a count and bestowing upon him regentved and other estates. As the inseparable companion the king, Moltke's influence soon became so boundless that the oreign diplomatists declared he could make and unmake inisters at will. Fortunately he was no ordinary favourite. aturally tactful and considerate, he never put difficulties in e way of the responsible ministers. Especially interesting Moltke's attitude towards the two distinguished statesmen ho played the leading parts during the reign of Frederick V., ohan Sigismund Schulin and the elder Bernstorff. For Schulin e had a sort of veneration. Bernstorff irritated him by his rand airs of conscious superiority. But though a Prussian ntrigue was set up for the supersession of Bernstorff by Moltke, he latter, convinced that Bernstorff was the right man in the ight place, supported him with unswerving loyalty. Moltke as far less liberal in his views than many of his contemporaries. e looked askance at all projects for the emancipation of the serfs, but, as one of the largest landowners of Denmark, he did much service to agriculture by lightening the burdens of the countrymen and introducing technical and scientific improvements which greatly increased production. His greatest merit, however, was the guardianship he exercised over the king, whose sensual temperament and weak character exposed him to many temptations which might have been very injurious to the state. Frederick had the good sense to appreciate the honesty of his friend and there was never any serious breach between them. On the death of Queen Louisa the king would even have married one of Moltke's daughters had he not peremptorily declined the dangerous honour. On the decease of Frederick V., who died in his arms (Jan. 14, 1766), Moltke's dominion was at an end. The new king, Christian VII., could not endure him, and exclaimed, with reference to his lanky figure: "He's stork below and fox above." He was also extremely unpopular, because he was wrongly suspected of enriching himself at the public expense.[1] In July 1766 he was dismissed from all his offices and retired to his estate at Bregentved. Subsequently, through the interest of Russia, to whom he had always been favourable, he regained his seat in the council (Feb. 8, 1768), but his influence was slight and of brief endurance. He was again dismissed without a pension, on the 10th of December 1770, for refusing to have anything to do with Struensee. He lived in retirement till his death on the 25th of September 1792.

His memoirs, written in German and published in 1870, have considerable historical importance. See H. H. Langhorn, *Historische Nachricht über die dänischen Moltkes* (Kiel, 1871). (R. N. B.)

MOLTKE, ADAM WILHELM, COUNT (1785–1864), Danish statesman, son of the minister Joachim Godske Moltke (1746–1818), and grandson of Adam Gottlob Moltke, was born at Einsiedelsborg in Funen, on the 25th of August 1785. Under the influence of the agricultural reformer Christian Colbjörnsen he abandoned the legal career he had adopted and entered the administrative service of the state, to which he devoted the remainder of his life. In 1831 he succeeded Johan Sigismund Mösting (1789–1843), as minister of finance. On the death of Christian VIII. he was one of the most prominent members of the Council of State, and when the constitutional crisis came in 1848 he seemed marked out as the man who could bridge over the gap between the old era and the new. The services which Count Moltke rendered to Denmark cannot be too highly appreciated. The mere fact that a distinguished statesman who had served the last two absolute kings of Denmark now voluntarily placed himself at the head of a ministry which included the most advanced of the popular agitators, gave the new government the hall-mark of stability and trustworthiness, whilst the fact that he still retained the ministry of finance was of itself a guarantee of security during the earlier years of a troublesome and costly war. It was this, his first administration, which introduced the constitution of the 5th of June 1849, and he also presided over the third constitutional ministry which was formed in July 1851; but he resigned on the 27th of January 1852, because he could not approve of the decree which aimed at transforming Denmark into a composite, indivisible, monarchy. Moltke continued to take part in public life as a member of the Landsting, or Upper House, but henceforth kept in the background. On the 2nd of October 1855 he was elected a member of the consultative Rigsraad, a position he continued to hold till 1863. He died on the 15th of February 1864.

MOLTKE, HELMUTH CARL BERNHARD, COUNT VON (1800–1891), Prussian field marshal, for thirty years chief of the staff of the Prussian army, the greatest strategist of the latter half of the 19th century, and the creator of the modern method of directing armies in the field, was born on the 26th of October 1800, at Parchim in Mecklenburg, of a German family of ancient nobility. His father in 1805 settled in Holstein and became a Danish subject, but about the same time was impoverished by the burning of his country house and the plunder by the French of his town house in Lübeck, where his wife and children were. Young Moltke therefore grew up in straitened circumstances. At the age of nine he was sent as a boarder to Hohenfelde in Holstein, and at the age of eleven to the cadet school at Copenhagen, being destined for the Danish army and court. In 1818 he became a page to the king of Denmark and second lieutenant in a Danish infantry regiment. But at twenty-one he resolved to enter the Prussian service, in spite of the loss of seniority. He passed the necessary examination with credit, and became second lieutenant in the 8th Infantry Regiment stationed at Frankfort-on-Oder. At twenty-three, after much less than the regulation term of service, he was allowed to enter the general war school, now the war academy, where he studied the full three years and passed in 1826 a brilliant final examination. He then for a year had charge of a cadet school at Frankfort-on-Oder, after which he was for three years employed on the military survey in Silesia and Posen. In 1832 he was seconded for service on the general staff at Berlin, to which in 1833 on promotion to first lieutenant he was transferred. He was at this time regarded as a brilliant officer by his superiors, and among them by Prince William, then a lieutenant-general, afterwards king and emperor. He was well received at court and in the best society of Berlin. His tastes inclined him to literature, to historical study and to travel. In 1827 he had published a short romance, *The Two Friends*. In 1831 it was followed by an essay entitled *Holland and Belgium in their Mutual Relations, from their Separation under Philip II. to their Reunion under William I.*, in which were displayed the author's interest in the political issues of the day, and his extensive historical reading. In 1832 appeared *An Account of the Internal Circumstances and Social Conditions of Poland*, a second study of a burning question based both on reading and on personal observation of Polish life and character. In 1832 he contracted to translate Gibbon's *Decline and Fall* into German, for which he was to receive £75, his object being to earn the money to buy a horse. In eighteen months he had finished nine volumes out of twelve, but the publisher failed to produce the book and Moltke never received more than £25, so that the chief reward of his labour was the historical knowledge which he acquired. He had already found opportunities to travel in south Germany and northern Italy, and in 1835 on his promotion as captain he obtained six months' leave to travel in south-eastern Europe. After a short stay in Constantinople he was requested by the sultan to enter the Turkish service, and being duly authorized from Berlin he accepted the offer. He remained two years at Constantinople, learned Turkish and surveyed for the sultan the city of Constantinople, the Bosporus and the Dardanelles. He travelled in the sultan's retinue through Bulgaria and Rumelia, and made many other journeys on both sides of the Strait. In 1838 he was sent as adviser to the Turkish general commanding the troops in Armenia, who was to carry on a campaign against Mehemet Ali of Egypt. During the summer he made extensive reconnaissances and surveys, riding several thousand miles in the course of his journeys, navigating the dangerous rapids of the Euphrates, and visiting and mapping many districts where no European traveller had preceded him since Xenophon. In 1839 the army moved south to meet the Egyptians, but upon the approach of the enemy the general became more attentive to the prophecies of the mollahs than to the advice of the Prussian captain. Moltke resigned his post of staff officer and took charge of the artillery, which therefore, in the ensuing battle of Nezib or Nisib, was the last portion of the Turkish army to run away. The Turks were well beaten and their army dispersed to the four winds. Moltke with infinite hardship made his way back to the Black Sea, and thence to Constantinople. His patron Sultan Mahmoud was dead, so he returned to Berlin where he arrived, broken in health, in December 1839. When he left Berlin in 1834 he had already "the courtier's, soldier's, scholar's eye, tongue, sword." When he returned it was with a mind expanded by a rare experience, and with a character doubly tempered and annealed. While away, he had been a constant letter-writer to his mother and sisters, and he now revised and published his letters as *Letters on Conditions and Events in Turkey in the Years 1835 to 1839*. No other book gives so deep an insight into the character of the Turkish Empire, and no other book of travels better deserves to be regarded as a German classic. One of his sisters had married an English widower named Burt, who had settled in Holstein. Her step-daughter, Mary Burt, had read the traveller's letters, and when he came home as a wooer was quickly won. The marriage took place in 1841, when Mary was just turned sixteen. It was a very happy union, though there were no children, and Moltke's love-letters and letters to his wife are among the most valuable materials for his biography. On his return in 1840 Moltke had been appointed to the staff of the 4th army corps, stationed at Berlin; he was promoted major on his wedding day. The fruits of his Eastern travels were by no means exhausted. He published his maps of Constantinople, of the Bosporus and of the Dardanelles, and, jointly with other German travellers, a new map of Asia Minor and a memoir on the geography of that country, as well as a number of periodical essays on various factors in the Eastern Question. In 1845 appeared *The Russo-Turkish Campaign in Europe, 1828–29, described in 1845 by Baron von Moltke, Major in the Prussian Staff*, a volume which was recognized by competent judges as a masterpiece of military history and criticism. Moltke at this period was much occupied with the development of railways. He was one of the first directors of the Hamburg–Berlin railway, and in 1843 published a review article entitled *What Considerations should determine the Choice of the Course of Railways?* which reveals a mastery of the technical questions involved in the construction and working of railway lines.

---

[1] He was said to be worth 10 million rix-dollars, but proved that he had less than one million.

In 1845 Moltke was appointed personal adjutant to Prince Henry of Prussia, a Roman Catholic who lived at Rome. He thus had the opportunity of a long stay in the Eternal City, with no more than nominal duties to perform. It was a life which he and his wife much enjoyed, and he spent much of his leisure in a survey, of which the result was a splendid map of Rome, published at Berlin in 1852. In 1846 Prince Henry died, and Moltke was then appointed to the staff of the 8th army corps at Coblenz. In 1848, after a brief return to the great general staff at Berlin, he became chief of the staff of the 4th army corps, of which the headquarters were then at Magdeburg, where he remained seven years, during which he rose to lieutenant-colonel (1850), and colonel (1851). In 1855 he was appointed first adjutant to Prince Frederick William (afterwards crown prince and emperor), whom he accompanied to England on his betrothal and marriage, as well as to Paris and to St Petersburg to the coronation of Alexander II. of Russia. Prince Frederick William was in command of a regiment stationed at Breslau, and there as his adjutant Moltke remained for a year, becoming major-general in 1856. On the 23rd of October 1857, owing to the serious illness of King Frederick William IV., Prince William became prince regent. Six days later the regent selected Moltke for the then vacant post of chief of the general staff of the army. The appointment was made definitive in January 1858. Moltke's posthumously published military works disclose a remarkable activity, beginning in 1857, devoted to the adaptation of strategical and tactical methods to changes in armament and in means of communication, to the training of staff officers in accordance with the methods thus worked out, to the perfection of the arrangements for the mobilization of the army, and to the study of European politics in connexion with the plans for campaigns which might become necessary. In 1859 came the war in Italy, which occasioned the mobilization of the Prussian army, and as a consequence the reorganization of that army, by which its numerical strength was nearly doubled. The reorganization was the work not of Moltke but of the king, and of Roon, minister of war; but Moltke watched the Italian campaign closely, and wrote a history of it, published in 1862, and attributed on the title-page to the historical division of the Prussian taff, which is the clearest account of the campaign and contains he best criticism upon it. In December 1862 Moltke was asked or an opinion upon the military aspect of the quarrel with Denmark then becoming acute. He thought the difficulty vould be to bring the war to an end, as the Danish army would f possible retire to the islands, where, as the Danes had the ommand of the sea, it could not be attacked. He sketched plan for turning the flank of the Danish army before the ttack upon its position in front of Schleswig, and hoped that y this means its retreat might be intercepted. When the var began in February 1864, Moltke was not sent with the Prussian forces, but kept at Berlin. The plan was mismanaged n the execution, and the Danish army escaped to the fortresses f Düppel and Fredericia, each of which commanded a retreat cross a strait on to an island. The allies were now checked; Düppel and Fredericia were besieged by them, Düppel taken y storm, and Fredericia abandoned by the Danes without ssault; but the war showed no signs of ending, as the Danish rmy was safe in the islands of Alsen and Fünen. On the 30th f April Moltke was sent to be chief of the staff to the commander-n-chief of the allied forces, and, so soon as the armistice of May and June was over, persuaded Prince Frederick Charles to ttempt to force the passage of the Sundewitt and attack the Danes in the island of Alsen. The landing was effected on the 9th of June, and the Danes then evacuated Alsen. Moltke ext proposed a landing in Fünen, but it was unnecessary. The Danes no longer felt safe in their islands, and agreed to the German terms. Moltke's appearance on the scene had quickly ransformed the aspect of the war, and his influence with the ing had thus acquired a firm basis. Accordingly, when in 866 the quarrel with Austria came to a head, Moltke's plans vere adopted and he was almost invariably supported in their xecution. A disciple rather of Clausewitz, whose theory of war vas an effort to grasp its conditions, than of Jomini, who exounded a system of rules, Moltke regarded strategy as a practical rt of adapting means to ends, and had developed the methods of Napoleon in accordance with the altered conditions. He had een the first to realize the great defensive power of modern rearms, and had inferred from it that an enveloping attack had ecome more formidable than the attempt to pierce an enemy's ront. He had pondered the tactics of Napoleon at Bautzen, vhen the emperor preferred to bring up Ney's corps, coming rom a distance, against the flank of the allies, rather than to nite it with his own force before the battle; he had also drawn moral from the combined action of the allies at Waterloo. t the same time he had worked out the conditions of the march nd supply of an army. Only one army corps could be moved long one road in the same day; to put two or three corps on he same road meant that the rear corps could not be made use f in a battle at the front. Several corps stationed close together n a small area could not be fed for more than a day or two. Accordingly he inferred that the essence of strategy lay in rrangements for the separation of the corps for marching and heir concentration in time for battle. In order to make a large rmy manageable, it must be broken up into separate armies or roups of corps, each group under a commander authorized to egulate its movements and action subject to the instructions f the commander-in-chief as regards the direction and purpose f its operations. In the strategy of 1866 the conspicuous oints are: (1) The concentration of effort. There were two roups of enemies, the Austro-Saxon armies, 270,000; and the orth and south German armies, 120,000. The Prussian forces vere 64,000 short of the adverse total, but Moltke determined o be superior at the decisive point against the Austro-Saxons; e therefore told off 278,000 men for that portion of the struggle, nd employed only 48,000 men in Germany proper. His brilliant direction enabled the 48,000 to capture the Hanoverian rmy in less than a fortnight, and then to attack and drive sunder the south German forces. (2) In dealing with Austro-Saxony the difficulty was to have the Prussian army first ready —no easy matter, as the king would not mobilize until after the Austrians. Moltke's railway knowledge helped him to save time. Five lines of railway led from the various Prussian provinces to a series of points on the southern frontier on the curved line Zeitz-Halle-Görlitz-Schweidnitz. By employing all these railways at once, Moltke had the several army corps moved simultaneously from their peace quarters to points on this curved line. When this first move was finished the corps then marched along the curve to collect into three groups, one near Torgau (Elbe army), another at the west end of Silesia (first army, Prince Frederick Charles), the third between Landshut and Waldenburg (second army, crown prince). The first army when formed marched eastwards towards Görlitz. The small Saxon army at Dresden now had the Elbe army in its front and the first army on its right flank, and as it was outnumbered by either of them, its position was untenable, and so soon as hostilities began fell back into Bohemia, where it was joined by an Austrian corps, with which it formed an advance guard far in front of the Austrian main army concentrated near Olmütz. The Elbe army advanced to Dresden, left a garrison there, and moved to the right of Prince Frederick Charles, under whose command it now came. (3) Moltke now had two armies about 100 miles apart. The problem was how to bring them together so as to catch the Austrian army between them like the French at Waterloo between Wellington and Blücher. If, as was thought likely, the Austrians moved upon Breslau, the first and Elbe armies could continue their eastward march to co-operate with the second. But on the 15th of June Moltke learned that on the 11th of June the Austrian army had been spread out over the country between Wildenschwerdt, Olmütz and Brünn. He inferred that it could not be concentrated at Josefstadt in less than thirteen days. Accordingly he determined to bring his own two armies together by directing each of them to advance towards Gitschin. He foresaw that the march of the crown prince would probably bring him into collision with a portion of the Austrian army; but the crown prince had 100,000 men, and it was not likely that the Austrians could have a stronger force than that within reach of him. The order to advance upon Gitschin was issued on the 22nd of June, and led to one of the greatest victories on record. The Austrians marched faster than Moltke expected, and might have opposed the crown prince with four or five corps; but Benedek's attention was centred on Prince Frederick Charles, and he interposed against the crown prince's advance four corps not under a common command, so that they were beaten in detail, as were also the Saxons and the Austrian corps with them, by Prince Frederick Charles. On the 1st of July Benedek collected his already shaken forces in a defensive position in front of Königgrätz. Moltke's two armies were now within a march of one another and of the enemy. On the 3rd of July they were brought into action, the first against the Austrian front and the second against the Austrian right flank. The Austrian army was completely defeated and the campaign decided, though an advance towards Vienna was needed to bring about the peace upon Prussia's terms. Moltke was not quite satisfied with the battle of Königgrätz. He had tried to have the Elbe army brought up to the Elbe above Königgrätz so as to prevent the Austrian retreat, but its general failed to accomplish this. He also tried to prevent the first army from pushing its attack, hoping in that way to keep the Austrians in their position until retreat should be cut off by the crown prince, but he could not restrain the impetuosity of Prince Frederick Charles and of the king. During the negotiations Bismarck, who dared not risk the active intervention of France, opposed the king's wish to annex Saxony and perhaps other territory beyond what was actually taken. Moltke would not have hesitated; he was confident of beating both French and Austrians if the French should intervene, and he submitted to Bismarck his plans in case of need for the opening moves against both French and Austrians.

After the peace, the Prussian Diet voted Moltke the sum of £30,000, with which he bought the estate of Creisau, near Schweidnitz, in Silesia. In 1867 was published *The Campaign of 1866 in Germany*, a history produced under Moltke's personal supervision, and remarkable for its combination of accuracy with reticence. On the 24th of December 1868 Moltke's wife died at Berlin. Her remains were buried in a small chapel erected by Moltke as a mausoleum in the park at Creisau.

In 1870 suddenly came the war with France. The probability of such a war had occupied Moltke's attention almost continuously since 1857, and a series of memoirs is preserved in which from time to time he worked out and recorded his ideas as to the best arrangement of the Prussian or German forces for the opening of the campaign. The arrangements for the transport of the army by railway were annually revised in order to suit the changes in his plans brought about by political conditions and by the growth of the army, as well as by the improvement of the Prussian system of railways. The great successes of 1866 had strengthened Moltke's position, so that when on the 15th of July 1870 the order for the mobilization of the Prussian and south German forces was issued, his plans were adopted without dispute and five days later he was appointed "Chief of the general staff of the army at the headquarters of his Majesty the King" for the duration of the war. This gave Moltke the right to issue in the king's name, though of course not without his approval, orders which were equivalent to royal commands. Moltke's plan was to assemble the whole army to the south of Mainz, this being the one district in which an army could best secure the defence of the whole frontier. If the French should disregard the neutrality of Belgium and Luxemburg, and advance on the line from Paris to Cologne or any other point on the Lower Rhine, the German army would be able to strike at their flank, while the Rhine itself, with the fortresses of Coblenz, Cologne and Wesel, would be a serious obstacle in their front. If the French should attempt to invade south Germany, an advance of the Germans up either bank of the Rhine would threaten their communications. Moltke expected that the French would be compelled by the direction of their railways to collect the greater part of their army near Metz, and a smaller portion near Strassburg. The German forces were grouped into three armies: the first of 60,000 men, under Steinmetz, on the Moselle below Trèves; the second of 131,000 men, under Prince Frederick Charles, round Homburg, with a reserve of 60,000 men behind it; the third under the crown prince of 130,000 men, at Landau. Three army corps amounting to 100,000 men were not reckoned upon in the first instance, as it was desirable to keep a considerable force in north-eastern Germany, in case Austria should make common cause with France. If, as seemed probable, the French should take the initiative before the German armies were ready, and for that purpose should advance from Metz in the direction of Mainz, Moltke would merely put back a few miles nearer to Mainz the points of debarcation from the railway of the troops of the second army. This measure was actually adopted, though the anticipated French invasion did not take place. Moltke's plan of operations was that the three armies while advancing should make a right wheel, so that the first army on the right would reach the bank of the Moselle opposite Metz, while the second and third armies should push forward, the third army to defeat the French force near Strassburg, and the second to strike the Moselle near Pont-à-Mousson. If the French army should be found during this advance in front of the second army, it would be attacked in front by the second army and in flank by the first or the third or both. If it should be found on or north of the line from Saarburg to Lunéville, it could still be attacked from two sides by the second and third armies in co-operation. The intention of the great right wheel was to attack the principal French army in such a direction as to drive it north and cut its communications with Paris. The fortress of Metz was to be observed, and the main German forces, after defeating the chief French army, to march upon Paris. This plan was carried out in its broad outlines. The battle of Wörth was brought on prematurely, and therefore led, not to the capture of MacMahon's army, which was intended, but only to its total defeat and hasty retreat as far as Châlons. The battle of Spicheren was not intended by Moltke, who wished to keep Bazaine's army on the Saar till he could attack it with the second army in front and the first army on its left flank, while the third army was closing towards its rear. But these unintended or unexpected victories did not disconcert Moltke, who carried out his intended advance to Pont-à-Mousson, there crossed the Moselle with the first and second armies, then faced north and wheeled round, so that the effect of the battle of Gravelotte was to drive Bazaine into the fortress of Metz and cut him off from Paris. Nothing shows Moltke's insight and strength of purpose in a clearer light than his determination to attack on the 18th of August, when many strategists would have thought that, the strategical victory having been gained, a tactical victory was unnecessary. He has been blamed for the last local attack at Gravelotte, in which there was a fruitless heavy loss; but it is now known that this attack was ordered by the king, and Moltke blamed himself for not having used his influence to prevent it. During the night following the battle Moltke made his next decision. He left one army to invest Bazaine and Metz, and set out with the two others to march towards Paris, the more southerly one leading, so that when MacMahon's army should be found the main blow might be delivered from the south and MacMahon driven to the north. On the 25th of August it was found that MacMahon was moving north-east for the relief of Bazaine. The moment Moltke was satisfied of the accuracy of his information, he ordered the German columns to turn their faces north instead of west. MacMahon's right wing was attacked at Beaumont while attempting to cross the Meuse, his advance necessarily abandoned, and his army with difficulty collected at Sedan. Here the two German armies were so brought up as completely to surround the French army, which on the 1st of September was attacked and compelled to raise the white flag. After the capitulation of Sedan, Moltke resumed the advance on Paris, which was surrounded and invested. From this time his strategy is remarkable for its judicious economy of force, for he was wise enough never to attempt more than was practicable with the means at his disposal. The surrender of Metz and of Paris was a question of time, and the problem was, while maintaining the investment, to be able to ward off the attacks of the new French armies levied for the purpose of raising the siege of Paris. Metz surrendered on the 27th of October, and on the 28th of January 1871 an armistice was concluded at Paris by which the garrison became virtually prisoners and the war was ended.

On the 29th of October 1870 Moltke was created graf (coun or earl), and on the 16th of June 1871, field marshal. Afte the war he superintended the preparation of its history, which was published between 1874 and 1881 by the great general staff In 1888 he resigned his post as chief of the staff. In 186 Moltke was elected to the North German Diet, and in 1871 to the Reichstag. His speeches, dealing mostly with military questions, were regarded as models of conciseness and relevancy He died suddenly on the 24th of April 1891, and after a magnificent funeral ceremony at Berlin his remains were laid besid those of his wife in the chapel which he had erected as her tomb at Creisau.

As a strategist Moltke cannot be estimated by compariso with Frederick or Napoleon, because he had not the authorit either of a king or of a commander-in-chief. While it is doubtfu whether he can be convicted of any strategical errors, it seem beyond doubt that he never had to face a situation which place any strain on his powers, for in the campaigns of 1866 and 187 his decisions seemed to be made without the slightest effort and he was never at a loss.

He had a tall spare figure, and in his latter years his tanne features had received a set expression which was at once har and grand. He was habitually taciturn and reserved, thoug a most accomplished linguist, so that it was said of him tha he was "silent in seven languages." The stern school of hi early life had given him a rare self-control, so that no indiscree or unkind expression is known to have ever fallen from him Long before his name was on the lips of the public he was know n the army and in the staff as the "man of gold," the ideal haracter whom every one admired and who had no enemies.

MOLUCCAS, or SPICE ISLANDS, a name which in its wider ense includes all the islands of the Malay Archipelago between Celebes on the W., New Guinea on the E., Timor on the S., and he open Pacific Ocean on the N. They are thus distributed ver an area between 2° 43′ N. and 8° 23′ S. and 124° 22′ nd 135° E., and include: (1) the Moluccas proper or Ternate roup, of which Halmahera is the largest and Ternate the capital; 2) the Bachian, Obi, and Xulla groups; (3) the Amboyna group, f which Ceram (Serang) and Buru are the largest; (4) the Banda slands (the spice or nutmeg islands *par excellence*); (5) the south-astern islands, comprising Timor-Laut or Tenimber, Larat, &c.; (6) the Kei Islands and the Aru Islands, of which the former re sometimes attached to the south-eastern group; and (7) he south-western islands or the Babar, Sermata, Leti, Damar, Roma and Wetar groups. At the close of the 16th century his part of the archipelago was divided among four rulers ettled at Ternate, Tidore, Halmahera and Bachian. The orthern portion belongs to the Dutch residency of Ternate, he southern portion to that of Amboyna.

The name Moluccas is said to be derived from the Arabic or "king." Argensola (1609) uses the forms *islas Malucas, Maluco*, and *el Maluco*; Coronel (1623), *islas del Moluco*; and Camoens, *Maluco*. Since 1867, when the political unity, under governor, was dissolved, the Moluccas are often named by he Dutch the "Great East" (*Groote Oost*). Most of the islands re mountainous, with still active volcanoes. As they lie near r under the equator, the monsoons blowing over them are less egular, and the rainfall, of large volume throughout the year, s dependent on the height and direction of the chains. The vegetation of the small and narrow islands, all encompassed y the sea, is very luxuriant, and the products, principally utmegs, mace, and other spices, include also rice and sago. The inhabitants are of mixed descent. In some islands are eople of obvious Papuan blood, while in others are Polynesian r Malayan tribes. With these three main races have crossed raders and colonists, Macassars, Buginese, Javanese and Europeans.

The geology of the Moluccas is very imperfectly known. The reat chain of volcanoes which runs through Sumatra and Java is ontinued eastwards into the Moluccas, and terminates in a hook-ke curve which passes through the Damar Islands to the Banda roup. Outside this hook lies a concentric arc of non-volcanic slands, including Tenimber, the Lesser Kei Islands, Ceram and Buru; and beyond is still a third concentric arc extending from Taliabu to the Greater Kei Islands. The islands of these outer rcs consist chiefly of crystalline schists and limestones, overlaid y Jurassic, Cretaceous and Tertiary deposits. On the whole it ppears that the older rocks are found more particularly towards he interior of the curve, and the newer rocks towards the exterior. Eruptive rocks of supposed Cretaceous age are met with in these uter islands, but Tertiary and recent volcanic lavas are confined to he innermost arc. Halmahera lies outside these arcs. It appears o consist chiefly of gabbro, peridotite, serpentine and other very asic eruptive rocks, which are believed to be of Cretaceous age. Nummulitic limestone occurs in the south-east. Upon the floor of lder rock rise a number of volcanoes, some of which are now extinct while others are still active. Most of them lie near the west coast or n the islands off this coast; and they are arranged in lines which un approximately from north to south, with, generally, a slight onvexity towards the west.

See further MALAY ARCHIPELAGO, and separate articles on the principal islands and groups.

MOLY (Gr. *μῶλυ*), a mysterious plant with magical powers escribed in Homer, *Odyssey*, x. 302–306. Hermes pulls it up nd gives it to Odysseus as a protection against the arts of Circe. It is further described as "having a black root and a ower like milk, and hard for mortals to pull up." There has een much controversy as to the identification. Philippe Champault—*Phéniciens et Grecs en Italie d'après l'Odyssée* (1906), pp. 504 seq.—decides in favour of the *Peganum harmala* (of the order Rutaceae), the Syrian or African rue (Gr. *πήγανον*), from the husks of which the vegetable alkaloid harmaline ($C_{13}H_{14}N_2O$) is extracted. The flowers are white with green stripes. Victor Bérard—*Les Phéniciens et l'Odyssée*, ii. 288 seq.—relying partly on a Semitic root, prefers the *Atriplex halimus* (*atriplex*, a Lat. form of Gr. *ἀτράφαξυς*, and *ἅλιμος*, marine), order Chenopodiaceae, a herb or low shrub common on the south European coasts. These identifications are noticed by R. M. Henry in *Class. Rev.* (Dec. 1906), p. 434, who illustrates the Homeric account by passages in the Paris and Leiden magical papyri, and argues that *moly* is probably a magical name, derived perhaps from Phoenician or Egyptian sources, for a plant which cannot be certainly identified. He shows that the "difficulty of pulling up" the plant is not a merely physical one, but rather connected with the peculiar powers claimed by magicians. In Tennyson's *Lotus Eaters* the moly is coupled with the amaranth ("propt on beds of amaranth and moly").

MOLYBDENITE, a mineral consisting of molybdenum disulphide, MoS_2. It closely resembles graphite in appearance, but may readily be distinguished from this by its greater density (4·7) and by its behaviour before the blowpipe. Crystals have the form of six-sided plates or scales, but they are never sharply defined, and their reference to the hexagonal system is doubtful. They have a perfect cleavage parallel to the large surface of the plates, and the flakes are readily bent, but are not elastic. The mineral is very soft ($H=1$ to $1\frac{1}{2}$) and unctuous, and makes a bluish-grey mark on paper: it is opaque and has a bright metallic lustre. The colour is lead-grey differing slightly from that of graphite in having a bluish tinge. The name molybdenite is from the Greek *μόλυβδος*, meaning lead or lead ore, with which graphite (black-lead) and molybdenite were confused; the latter was distinguished by P. J. Hjelm, who in 1782 discovered the element molybdenum in this mineral.

Molybdenite occurs as disseminated scales in crystalline rocks—such as granite, gneiss, schist and marble—and also in quartz-veins. It has been found in small amounts at many localities, but only those which have yielded large crystals need be specially mentioned here, viz. in a pyroxene-rock at Aldfield in Pontiac county, Quebec; with native bismuth at Kingsgate in Gough county, New South Wales; with wolframite and scheelite in quartz-veins at Caldbeck Fells in Cumberland; and recently, as crystals 6 in. across, at Slangsvold near Raade in Norway.

Molybdenite has been used mainly for the preparation of molybdates for use as chemical reagents. Recently, however, it has been used in the manufacture of molybdenum steel (ferro-molybdenum), which by reason of its hardness and toughness is specially suitable for tools. (L. J. S.)

MOLYBDENUM [symbol, Mo; atomic weight, 96 ($O=16$)] a metallic chemical element. The name is derived from Gr. *μόλυβδος*, lead, and was originally employed to denote many substances containing or resembling lead; ultimately the term was applied to graphite and to molybdenum sulphide. The difference between these two latter substances was first pointed out by Cronstedt, and in 1778 C. Scheele prepared molybdic acid from the sulphide. Molybdenum occurs in nature chiefly as the minerals molybdenite (MoS_2) and wulfenite ($PbMoO_4$), and more rarely as molybdic ochre (MoO_3) and ilsemannite; it also occurs in many iron ores. The metal may be obtained by heating the trioxide with carbon in the electric furnace (H. Moissan, *Comptes rendus*, 1893, 116, p. 1225), or by the Goldschmidt method (Rosenheim and Braun, *Zeit. anorg. Chem.*, 1905, p. 311) or by dissociating the tetra- and pentachloride in a graphite crucible with an electric current below 1330° (J. N. Pring and W. Fielding, *Jour. Chem. Soc.*, 1909, 95, p. 1497). It forms a grey coloured powder of specific gravity 9·01; it is malleable, and not as hard as glass. It is rapidly oxidized on heating to a temperature of 500°–600° C., and also when fused with nitre or potassium chlorate. It is soluble in dilute nitric acid, and in concentrated sulphuric acid; in the latter case with the formation of a blue solution which on heating becomes colourless, molybdenum trioxide being formed with the liberation of sulphur dioxide.

Molybdenum combines with oxygen to form many oxides, the most important of which are: the monoxide, $MoO.n(H_2O)$, the sesquioxide, Mo_2O_3, the dioxide, MoO_2, and the trioxide, MoO_3. *Molybdenum monoxide*, $MoO.n(H_2O)$, is a black powder obtained when the dichloride is boiled with concentrated potash solution. According to W. Muthmann and W. Nagel (*Ber.*, 1898, 31, p. 2009), this oxide does not exist, the reaction leading to the formation of an hydroxide according to the equation: $Mo_3Cl_4(OH)_2 + 4KHO + 3H_2O = 3Mo(OH)_3 + 4KBr + 3H$. *Molybdenum sesquioxide*, Mo_2O_3, a black mass insoluble in acids, is formed by heating the corresponding hydroxide *in vacuo*, or by digesting the trioxide with zinc and hydrochloric acid. *Molybdenum dioxide*, MoO_2, is formed by heating sodium trimolybdate, $Na_2Mo_3O_{10}$, to redness in a current of hydrogen (L. Svanberg and H. Struve, *Jour. prak. Chem.*, 1848, 44, p. 301), or by long fusion of a mixture of ammonium molybdate, potassium carbonate, and boron trioxide (W. Muthmann, *Ann.*, 1887, 238, p. 114). It forms quadratic prisms, having a violet reflex and insoluble in boiling hydrochloric acid. *Molybdenum trioxide*, MoO_3, is prepared by oxidizing the metal or the sulphide by heating them in air, or with nitric acid. It is a white powder, which turns pale yellow on heating, and melts at a red heat. It sublimes in small rhombic tables or needles, and is slightly soluble in cold water, the solution possessing an acid reaction. Several hydrated forms of the oxide are known, and a colloidal variety may be obtained by the dialysis of a strong hydrochloric acid solution of sodium molybdate. Molybdenum trioxide, like chromium trioxide, is an acidic oxide, and forms salts known as molybdates. The normal molybdates show a tendency to pass into polymolybdates. The molybdates are also capable of combining with other oxides (such as phosphorus and arsenic pentoxides) yielding very complex salts. The ordinary *ammonium molybdate*, used as a test reagent for phosphates, is a salt of composition $(NH_4)_{10}MO_{12}O_{41}$; it has been examined physicochemically by J. Sand and F. Eisenlohr (*Abst. J.C.S.*, 1907, ii. pp. 178, 179). The molybdates may be recognized by the fact that they give a white precipitate on the addition of hydrochloric or nitric acids to their solutions, and that with reducing agents (zinc and sulphuric acid) they give generally a blue coloration which turns to a green and finally to a brown colour.

Molybdenum combines with the halogen elements in varying proportions, forming with chlorine a di-, tri-, tetra- and penta-chloride, and similar compounds with bromine and iodine. *Molybdenum dichloride* $(MoCl_2)_3$ or $Cl_4Mo_3Cl_2$ (chlormolybdenum chloride), is prepared (together with some tetrachloride) by heating the trichloride in a stream of carbon dioxide (C. W. Blomstrand, *Jour. f. prak. Chem.*, 1857, 71, p. 449; 1861, 82, p. 433). It is a yellow amorphous powder which is soluble in dilute alkalis, the solution on acidification giving an hydroxide, $Cl_4Mo_3(OH)_2$, which is soluble in nitric acid, and does not give a reaction with silver nitrate. The molecular weight determinations of W. Muthmann and W. Nagel (*Ber.*, 1898, 31, p. 2009) show the salt to possess the composition Mo_3Cl_6. *Molybdenum trichloride*, $MoCl_3$, is obtained when the pentachloride is heated to a temperature of about 250° C. in a current of hydrogen. It forms red crusts, is insoluble in cold water, but is decomposed by boiling water. It is easily soluble in hot nitric acid. *Molybdenum pentachloride*, $MoCl_5$, is obtained when molybdenum is gently heated in dry chlorine (L. P. Liechti and B. Kempe, *Ann.*, 1873, 169, p. 345). It is a dark-coloured crystalline solid which melts at 194° C. and boils at 268° C. It fumes in moist air and deliquesces gradually. It is occasionally used as a chlorine carrier. It is soluble in absolute alcohol and in ether. *Molybdenum disulphide*, MoS_2, is found as the mineral molybdenite, and may be prepared by heating the trioxide with sulphur or sulphuretted hydrogen. It is a black crystalline powder, resembling graphite in appearance. It is readily oxidized by nitric acid, and when strongly heated in a current of hydrogen is reduced to the metallic condition. *Molybdenum trisulphide*, MoS_3, is obtained by saturating a solution of an alkaline molybdate with sulphuretted hydrogen and adding a mineral acid. It is a brown powder which on heating in air loses sulphur and leaves a residue of the disulphide. A *tetrasulphide*, MoS_4, has also been described.

Many varying values have been given for the atomic weight of molybdenum. J. J. Berzelius (*Pogg. Ann.*, 1826, 8, p. 23), by converting lead molybdate into lead nitrate, obtained the value 95·2; while J. B. A. Dumas (*Ann.*, 1860, 113, p. 32), by converting the trioxide into the metal, obtained the value 95·65. K. Seubert and W. Pollard (*Zeit. anorg. Chem.*, 1895, 8, p. 434) using this second method obtained the value 96·28; whilst E. F. Smith and P. Maas (*Zeit. anorg. Chem.*, 1894, 5, p. 280), by heating pure sodium molybdate in hydrochloric acid and estimating the amount of sodium chloride formed, obtained the value 96·087.

MOLYNEUX. This historic English name came into the country from France at the time of the Norman Conquest through William de Molines (Moleyns, Molyneux), who obtained a grant of Sefton, in Lancashire, whence come the earls of Sefton to-day. His descendant Adam de Molyneux (Moleyns or Molins), who died in 1450, was bishop of Chichester and keeper of the privy seal; he was a son of Sir Richard Molyneux of Sefton, and uncle of the Sir Richard Molyneux (d. 1459), the Lancastrian and favourite of Henry VI., whose descendant Richard Molyneux (1593–1636) was created in 1628 1st Viscount Molyneux of Maryborough, a title now merged in that of Sefton (created 1771). Another Molyneux family of some importance is the Irish one, descended from Sir Thomas Molyneux (1531–1597), Irish chancellor of the exchequer, who, born at Calais, settled in Ireland in 1576. He was the great-grandfather of Sir Thomas Molyneux, Bart. (1661–1733), a well-known physician and zoologist, and of William Molyneux (1656–1698), the philosopher, astronomer and politician, the friend of Locke, and author of *Dioptrica nova* (1692), whose famous work on the legislative independence of Ireland (*The Case of Ireland*, &c. 1698) created much stir at the time. The latter's son Samuel Molyneux (1689–1728), was also a well-known astronomer.

MOMBASA, the principal seaport of British East Africa, in 4° 4′ S., 39° 43′ E., 150 m. N. of Zanzibar. Pop. about 30,000. Mombasa is built on a coralline island which nearly fills the mouth of a deep arm of the sea. The channel on either side of the island—Mombasa to the N.E., Kilindini to the S.W.—affords safe harbourage, and each leads to a deeper ramification of the sea, Mombasa Harbour to Port Tudor, Kilindini Harbour to Port Reitz. Mombasa town is on the N.E. side of the island, 2 m. from Kilindini, with which it is connected by rail and tramways. Viewed from the sea Mombasa has a picturesque appearance, the most conspicuous object being the fort, built on a coral hill 40 ft. high. Except for the main street and Government Square (close to the harbour and containing the customs-house and other official buildings), Mombasa proper presents the usual aspect of an Oriental city—a maze of narrow, irregular streets and lanes. To the south, overlooking the sea, is the European suburb. There are Anglican and Roman Catholic churches (the Roman Catholic church and mission house is one of the finest buildings in Mombasa), mission schools, Hindu, Parsee, and Mahommedan temples, and hospitals and law courts, the last named completed in 1902. Built into the façade of the courts is a stone with an inscription recording the building of a fort, dedicated to St Joseph, by the Portuguese at Kilindini in 1666. This stone was found in the ruins of Fort St Joseph. Mombasa Fort, or citadel, quadrangular in form, was built by the Portuguese in 1593–1595 (as an inscription in the interior testifies), was dedicated to the Saviour, and known as the Jesus Fort. It bears the symbol I.H.S. The fort was repaired by Seixas de Cabreira in 1635, the restoration being recorded in an inscription over the gateway. By the British authorities the fort is used as a military store and central gaol. In the public garden on the point of the town facing the sea a bronze statue of Sir William Mackinnon—to whom Mombasa owes its renaissance—has been placed. The population of the city is cosmopolitan, with three well-marked racial distinctions: the Arab (Swahili), the Indian and the European. The climate is fairly healthy, and Europeans live there with comfort.

The harbour at Mombasa is more than a mile in length but only 1200 ft. in width. It is consequently not so suitable for large ships as Kilindini ("the place of deep water"), which possesses the finest land-locked harbour on the East Coast o Africa. The entrance is about the same width as that o Mombasa, but Kilindini Harbour widens to ½ m. and is 3 m. long, the depth of water varying from 25 to 30 fathoms. Kilindini is a depot of the British navy. Port Reitz, which opens out of Kilindini Harbour westward, is 4 m. long and 1 m. broad, with excellent anchorage. At Kilindini is a pier alongside which ships 450 ft. in length and drawing 27 ft. can load and unload cargo. Here is the virtual terminus of the Uganda railway, and the offices, workshops and hospita connected therewith, also a branch customs-house. The Uganda railway crosses to the mainland on a bridge, ½ m. long, buil over the shallow channel which on the north-west separates the island from the continent. Mombasa is the outlet for the produce of a large tract of territory, including the European settlements in the highlands of the protectorate, and by means of the railway to Victoria Nyanza taps the rich regions of the Nile sources. German, British, French and Austrian mail-boats call regularly at the port, which is connected by submarine cable with Zanzibar. Trade statistics are included in those of British East Africa (*q.v.*).

Mombasa Island (named after the town) is 3 m. long by 2½ m. broad, with an area of 9 sq. m. Except at the western end, the coast of the island consists of cliffs from 40 ft. to 60 ft. high. The island contains many fertile plantations, chiefly of coco-nut palms, except on the side facing the ocean, where there is little vegetation, the coral reefs being but thinly covered with earth. There are no springs and the island is dependent for water on rain collected in tanks or drawn from wells—the latter brackish. Ruins of Arab, Portuguese and Turkish buildings are found in various parts of the island. At Ras Serani are the ruins of a chapel "Nossa Senhora das Merces," built by the Portuguese in the 17th century on the site of a Turkish fort, and afterwards turned into a fort again by the Arabs.

Mombasa takes its name from Mombasa in Oman. A Perso-Arabic settlement was made here about the 11th century. It is mentioned by Ibn Batuta in 1331 as a large place, and at the time of Vasco da Gama's visit (1498) it was the seat of considerable commerce, its inhabitants including a number of Calicut Banyans and Oriental Christians. The ruler of the city tried to entrap da Gama (or so the Portuguese navigator imagined), and with this began a series of campaigns which gave full force to its Swahili name *Mvita* (war). The principal incidents are the capture and burning of the place by Almeida (1505), Nuno da Cunha (1529), and Duarte de Menezes (1587)—this last as a revenge for its submission to the sultan of Constantinople—the revolt and flight (1631) of Yusuf ibn Ahmed (who murdered all the Portuguese in the town—over 100), and the three-years' siege by the imam of Omam 1696–98(the garrison being reduced to eleven men and two women), ending in the expulsion of the Portuguese. From the 12th of March 1728 to the 29th of November 1729 a Portuguese force from Goa again held Mombasa, when they were finally driven out by the Muscat Arabs. In December 1823 the Mazrui family, who had ruled in Mombasa from the early part of the 18th century, first as representatives of Oman, afterwards as practically independent princes, placed the city under British protection; and in February 1824 Lieut. J. J. Reitz was appointed commandant or resident at the city by Captain (afterwards Vice-Admiral) W. F. W. Owen. Reitz, after whom Port Reitz is named, died at Mombasa either in 1824 or 1825. The protectorate was repudiated by the British government, which left the place to be bombarded and captured by Seyyid Said of Oman, who made repeated attacks between 1829 and 1833, and only got possession in 1837 by treachery. Said thereafter made Zanzibar his capital, Mombasa becoming of secondary importance. A revolt against Zanzibar in 1875 was put down with British assistance. The British government in the following year vetoed a proposal by the khedive Ismail to annex Mombasa and its hinterland up to the equatorial lakes to Egypt—a project which originated with General C. G. Gordon, when that officer administered the Upper Nile provinces. In 1887 the city was handed over by the sultan of Zanzibar to the British for administration. It became the capital of the province of Seyyidie and of the East Africa protectorate. In 1907, however, the seat of the central government was removed to Nairobi (*q.v.*). Mombasa still forms, nominally, part of the sultanate of Zanzibar. The city, together with Malindi, is mentioned in *Paradise Lost.*

MOMEIN, the Burmese name of the Chinese city Têng-yueh-chow, in the S.W. of the province of Yunnan, China. It was opened to foreign trade by the Burmese Convention of 1897, but so far no advantage has been taken of the permission. It lies close to the Burmese frontier and on the old trade route from Bhamo to Yunnan, but its importance as an outpost of the British Empire is political rather than commercial. The distance from Têng-yueh to Bhamo by the usual trade route is 160 m., and is generally traversed by pack-animals in seven or eight days. In a straight line the two towns are only 80 m. apart. Near Momein and within its jurisdiction is the frontier town of Manwyne, where A. R. Margary was assassinated in January 1875.

MOMMSEN, THEODOR (1817–1903), German historian and archaeologist, was born on the 30th of November 1817 at Garding, in Schleswig. After being educated at the university of Kiel he devoted himself to the study of Roman law and antiquities. In 1843 a grant from the Danish government enabled him to undertake a journey to Italy, which was to be decisive for his future career. There he began the study of Roman inscriptions, in association with other Italian and German scholars, especially Borghesi, de Rossi and Henzen. His first work was directed to the restoration of the old Italian dialects, and the French government, which at one time proposed to undertake the task of compiling a complete collection of all extant Roman inscriptions, asked for his co-operation. When they gave up the project it was taken up by the Berlin Academy, which had recently completed the collection of Greek inscriptions edited by Boeckh. They had already made a grant to Mommsen, and in 1844 Savigny proposed that he should be appointed to carry out the great work. Many years, however, passed before the plan was finally approved. Meanwhile Mommsen continued his work in Italy: he drew up a full memorandum explaining the principles on which a *Corpus inscriptionum* should be compiled, and on which alone he could undertake the editorship. As a specimen he collected the inscriptions of Samnium, and in 1852 published those of the kingdom of Naples. These works caused him to be recognized as the first authority in this field of learning. In 1847, however, he was obliged to return to Germany: he first went to Schleswig, where during the Revolution he edited a paper in which he supported the claims of the Elbe Duchies; at the end of 1848 he was appointed professor of civil law at Leipzig. His work there was interrupted by his political opinions. During 1848, when the extreme party was in the ascendant, Mommsen supported the monarchy against the Republicans. With characteristic courage and independence, next year, when the Revolution had spent its force and Beust executed his *coup d'état*, he protested, with many of his colleagues, against this act. In consequence he was summoned before a disciplinary court, and, together with Haupt and Jahn, dismissed from his professorship.

Mommsen found an asylum in Switzerland, and became professor at Zurich: he repaid the hospitality of the Republic by writing exhaustive monographs on Roman Switzerland. His spare time was occupied with the *Roman History*, the three volumes of which appeared between 1854 and 1856. His name at once became known throughout Europe. In this work, with a true insight into the relative importance of things, he passed over with a few strong broad touches the antiquarian discussions on the origins of the city, on which previous historians had laboured so long; but in place of this he painted with astonishing vigour the great political struggle that accompanied the fall of the republic. It was, above all, his new reading of old characters which demanded attention, if not always approval: Cicero, the favourite of men of letters, was for him "a journalist in the worst sense of the word"; Pompey, the hero of Plutarch and the Moralists, was brushed aside as a mere drill-sergeant; and the book culminated in the picture of Caesar, who established absolute rule in the name of democracy, "the complete and perfect man."

The three volumes ended with the dictatorship of Caesar. The book has never been continued, for the volume on the *Roman Provinces under the Empire*, which appeared in 1884, is in reality a separate work. Mommsen was henceforward fully occupied with work of a more technical nature. In 1854 the definite offer was made to him by the Academy that he should be chief editor of a *Corpus inscriptionum*, with full control, and in order that he might carry on the work he was appointed in 1858 to a professorship at Berlin. The first volume appeared in 1861; five of the succeeding volumes he edited himself, and the whole was executed under his immediate supervision and with the co-operation of scholars whom he had himself trained.

Enormous as was the labour, this task occupied only a small part of his extraordinary intellectual energy. He found time to write two larger works, the *History of the Roman Coinage* and the *Römisches Staatsrecht*, a profound analysis of Roman constitutional law, and *Römisches Strafrecht*, on Roman criminal jurisdiction. His *Roman Provinces* already mentioned gives a singularly interesting picture of certain aspects of social life under the empire. His smaller papers amount to many hundreds in number, and there is no department of Roman life and learning, from the earliest records of the Roman law to the time of Jornandes, which he has not illuminated. As secretary to the Berlin Academy for over twenty years he took a leading part in their deliberations, and was their spokesman on great occasions. His interest in political problems of the present was as keen as in those of the past. He was one of the founders of the *Preussische Jahrbücher*, the most influential of German political periodicals. For many years he was a member of the Prussian Parliament. His political opinions were strong but ill-regulated. Intensely nationalist, he acquiesced in the annexation of his native land to Prussia, and in a public letter to the Italian nation in 1870 defended the German cause before the nation which had become to him a second fatherland; but he was of too independent a character ever to be quite at ease under Prussian government. Loving liberty, he hated its consequences; a democrat, he had and always expressed a profound contempt for the mob. Like many idealists, he was a severe critic of the faults of his own and other countries, and he added something to the increasing Chauvinism in Germany.

It was, however, above all, German scholarship which remained his first interest. There is probably no other instance in the history of scholarship in which one man has established so complete an ascendancy in a great department of learning. Equally great as antiquary, jurist, political and social historian, he lived to see the time when among students of Roman history he had pupils, followers, critics, but no rivals. He combined the power of patient and minute investigation with a singular faculty for bold generalization and the capacity for tracing out the effects of thoughts and ideas on political and social life. Partly, perhaps, owing to a philosophical and legal training, he had not the gift of clear and simple narrative, and he is more successful in discussing the connexion between events than in describing the events themselves. Though his *History* ends with the fall of the republic, his most enduring work has been that on the empire; and if he has not written the history of the empire, he has made it possible for others to do so.

Mommsen died at Charlottenburg on the 1st of November 1903. His brothers, Carl Johann Tycho (1819–1900), a great authority on Pindar and Shakespeare, and August (b. 1821), who wrote chiefly on ancient chronology and Greek festivals, were also prominent among German scholars in their day.

The *History of Rome* (including the volumes of the provinces) has been translated into English by W. P. Dickson (the *Provinces*, revised by F. Haverfield, 1909); there is a French edition of his work on *Roman Coinage*. Many of his pamphlets and articles have been collected under the title *Römische Forschungen*. Of his other works, the more important are the *Roman Chronology to the Time of Caesar* (1858), a work written in conjunction with his brother August; his editions of the *Monumentum Ancyranum* and of the *Digest* in the *Corpus juris civilis*, and of the *Chronica* of Cassiodorus in *Monumenta Germaniae historica*, the *Auctores antiquissimi* section of which was under his supervision. A great part of his work is to be found in the German learned publications such as *Hermes*, *Rheinisches Museum*, &c. His *Reden und Aufsätze* and *Gesammelte Schriften*, i. ii., were published after his death. A full list of his works is given by Zangemeister, *Mommsen als Schriftsteller* (1887; continued by Jacobs, 1905). See also monographs by C. Bardt (1903) and Gradenwitz (1904, in the *Zeitschrift der Savigny-Stiftung für Rechtsgeschichte*), and O. Hirschfeld, *Gedächtnisrede auf Theodor Mommsen* (1904).

MOMORDICA, in botany, a genus of annual or perennial climbing herbs belonging to the natural order Cucurbitaceae, natives of the tropics, especially Africa, and known in cultivation chiefly as hothouse plants. They are grown for their ornamental fleshy fruits, which are oblong to cylindrical in shape, orange to red in colour, prickly or warted externally, and burst when ripe, generally with elastic force, into irregular valves. *M. Balsamina*, known as balsam apple, is a very pretty annual, well adapted for trellises, &c., in warm outside situations.

MOMUS, in Greek mythology, the son of Νύξ (Night), the personification of censoriousness. He is frequently mentioned in Lucian as the lampooner of the gods. It is said that Pallas, Hephaestus, and Poseidon entered into a competition as to which of them could create the most useful thing. Hephaestus made a man, Poseidon an ox, Pallas a house. Momus, being called upon to pronounce an opinion as to the merits of these productions, expressed dissatisfaction with all: with the man, because a window ought to have been made in his breast, through which his heart could be seen; with the ox, because its horns were in the wrong place; with the house, because it ought to have been portable, so as to be easily moved to avoid unpleasant neighbours. Momus is reported to have burst with chagrin at being unable to find any but the most trifling defects in Aphrodite. He is represented sometimes as a young, sometimes as an old man, wearing a mask, and carrying a fool's bauble.

Hesiod, *Theogony*, 214; Lucian, *Hermotimus*, 20, and especially *Deorum Concilium*; Philostratus, *Epistolae*, 37.

MONA, the name used by classical writers, and in particular by Tacitus, to denote Anglesey (*q.v.*). This island was raided by the Roman general Suetonius about A.D. 60 and conquered by Agricola about A.D. 79. The Romans probably mined coppe there, but no trace has yet been found of any Roman military post, and the villages of the inhabitants which have been recently excavated show only mediocre traces of Roman civilization. The name Mona seems also to have been occasionally used, perhaps from ignorance, for the other large island lying betwee England and Ireland, Man. The ancient name of this latte was probably not unlike that of Mona, but is not accuratel known to us (? Monapia, Manavia). (F. J. H.)

MONACO, a territory of south-eastern France, the smallest o the sovereign principalities of Europe. Area about 8 sq. m., the length being 2¼ m. and the width varying from 165 to 1100 yds. Pop. (1900), 15,180. Monaco is situated on the coast of the Mediterranean, 9 m. east of Nice, and is bounded on all sides by the French department of Alpes-Maritimes. It includes the towns of Monaco (3292), Condamine (6218) and Monte Carl (3794). The principality at one time included Mentone an Roccabruna, now known as Roquebrune, which towns, however were ceded to France in 1861 for a sum of four million francs The town of Monaco occupies the level summit of a rocky headland, rising about 200 ft. from the shore, and still defende by ramparts. Though largely modernized, the palace is an interesting specimen of Renaissance architecture; the "cathedral" (Romanesque-Byzantine style), and the oceanographical museum may also be mentioned. For this museum a fine building appropriately decorated, was opened in March 1910 by the princ of Monaco. It stands on the edge of the cliff rising from the se at the gardens of St Martin, and was designed to house th collections made by the prince during twenty-five years o oceanographical research, and others. Behind the rock, betwee Mont Tête de Chien and Mont de la Justice, the high grounds ris towards La Turbie, the village on the hill which takes its nam from the *tropaea* with which Augustus marked the boundar between Gaul and Italy. On the north lies the bay of Monac along the lower ground on the west of the bay stretches the healt and bathing resort of Condamine, with orange-gardens, manufactures of perfumes and liqueurs, and the chapel of Ste Dévot the patron saint of Monaco; to the north of the bay on the rock slopes of the Spélugues (speluncae) are grouped the variou buildings of the Casino of Monte Carlo with the elaborate garden and the numerous villas and hotels which it has called int existence. Adjoining the Casino terrace and overlooking th sea is the pigeon-shooting ground, the competitions on which ar celebrated.

There appear to have been gambling-tables at Monte Carl the year 1856, but it was in 1861 that François Blanc, seeing is tenancy at Homburg coming to an end, with no hope of enewal, obtained a concession for fifty years from Charles III. his concession passed into the hands of a joint-stock company, hich in 1898 obtained an extension to 1947, in return for a ayment to the prince of £400,000 in 1899 and of £600,000 in 913, together with an increase of the annual tribute of £50,000 £70,000 in 1907, £80,000 in 1917, £90,000 in 1927, and £100,000 1937. None of the inhabitants of Monaco have access to the bles; and their interest in the maintenance of the *status quo* secured by their complete exemption from taxation and the rge prices paid for their lands. The ruler of the principality, rince Albert, born 1848, succeeded his father, Prince Charles II., in 1889. He married in 1869 Lady Mary Douglas Hamilton, y whom in 1870 he had a son, Prince Louis: that marriage was, owever, annulled in 1880, and subsequently Prince Albert arried Alice, dowager-duchess of Richelieu, from whom he was ivorced in 1902. The prince is absolute ruler, as there is no arliament in the principality. He is advised by a small council state, the members of which are appointed by himself. The aire and other municipal authorities are also appointed by the rince. A governor-general presides over the administration. he judicial system is the same as that of France, there being a ourt of first instance and a juge de paix. By arrangement, wo Paris judges form a court of appeal. Monaco is the seat of a oman Catholic bishop.

A temple of Heracles seems to have been built on the Monaco eadland by the Phoenicians at a very early date, and the same od was afterwards worshipped there by the Greeks under the urname of Μόνοικος, whence the name Monaco. Monoeci ortus or Portus Herculis is frequently mentioned by the later atin writers. From the 10th century the place was associated ith the Grimaldi, a powerful Genoese family who held high ffices under the republic and the emperors; but not till a much ter date did it become their permanent possession and residence. the beginning of the 14th century it was notorious for its iracies. Charles I. (a man of considerable mark, who, after oing great service by sea and land to Philip of Valois in his nglish wars, was severely wounded at Crecy) purchased entone and Roccabruna, and bought up the claims of the pinola to Monaco. The princes of Monaco continued true to rance till 1524, when Augustin Grimaldi threw in his lot with harles V. Honoré I., Augustin's successor, was made marquis Campagna and count of Canosa, and people as well as rulers ere accorded various important privileges. The right to xact toll from vessels passing the port continued to be exercised ll the close of the 18th century. Honoré II. in 1641 threw off he supremacy of Spain and placed himself under the protec-orate of France; he was compensated for the loss of Canosa, &c., ith the duchy and peerage of Valentinois and various lesser rdships; and "duke of Valentinois" long continued to be the tle of the heir-apparent of the principality. In 1731 Antoine, s great-grandson, was succeeded by his daughter Louise ippolyte; she had married Jacques Goyon, count of Matignon nd Thorigny, who took the name of Grimaldi and succeeded is wife. The National Convention annexed the principality France in 1793; restored to the Goyon Grimaldis by the reaty of Paris in 1814, it was placed by that of Vienna under the rotection of Sardinia. The Sardinian government took the pportunity of disturbances that occurred in 1848 to annex entone and Roccabruna, which were occupied by a Sardinian arrison till 1859. With the transference of Nice to France in 860 the principality passed again under French protection.

See H. Métivier, *Monaco et ses princes*, La Flèche (1862).

MONAD (Gr. μονάς, unit, from μόνος, alone), a philosophic rm which now has currency solely in its connexion with the hilosophy of Leibnitz. In the earlier Greek philosophy the rm meant unity as opposed to duality or plurality; at a later me it meant an individual, or, with the Atomists, an atom. It as first used in a sense approximate to that of Leibnitz by runo, who meant by it a primary spiritual element as opposed the material atom. Leibnitz, however, seems to have borrowed the term not directly from Bruno, but from a contemporary, Van Helmont the younger. Leibnitz's view of things is that the world consists of monads which are immaterial centres of force, each possessing a certain grade of mentality, self-contained and representing the whole universe in miniature, and all combined together by a pre-established harmony. Material things, according to Leibnitz, are in their ultimate nature composed of monads, each soul is a monad, and God is the *monas monadum*. Thus monadism, or monadology, is a kind of spiritual atomism. The theory has been revived in recent years by C. B. Renouvier.

MONADNOCK, a term derived from Mount Monadnock in New Hampshire, U.S.A., to denote the "isolated remnants of hard rock which remain distinctly above their surroundings in the late stages of an erosion cycle" (T. C. Chamberlin, R. D. Salisbury). Examples are frequently found where a hard pipe of igneous rock surrounded by softer rock is gradually exposed by the washing away of the softer rock and becomes a conspicuous feature of the landscape, forming a volcanic "neck," and finally, in the later stages of erosion, a stump. The Peak Downs, Queensland, furnish many examples, and Mato Tepee, Wyoming, is a remarkably conspicuous instance of this type of formation.

MONAGHAN, a county of Ireland in the province of Ulster, bounded E. by Armagh, S.E. by Louth, S. by Meath, S.W. by Cavan, W. by Fermanagh, and N. by Tyrone. The area is 319,741 acres, or about 496 sq. m. The north-western part of the country is included in the great central plain of Ireland; but to the south and east the surface is irregular, although none of the hills is of great elevation. The principal range is that of Slievebeagh, a rugged and barren tract extending into the county Fermanagh, its highest summit being 1254 ft. above sea-level. The principal rivers are the Finn, which rises near the centre of the county and passes into Fermanagh, and the Blackwater, which forms the boundary with Tyrone. The Ulster Canal passes the towns of Monaghan and Clones, affording communication between Lough Neagh and Lough Erne. In geological structure the county drops from the Upper Carboniferous outlier of Slievebeagh in the north-west to a Carboniferous Limestone area towards Monaghan town; but south of this a tumbled Silurian area stretches across the Cavan and Armagh borders. At Carrickmacross, an outlier of Carboniferous Limestone, Coal Measures (with poor seams of coal) and Trias is encountered. Gypsum has been quarried in the Trias, and lead ore was formerly mined in many places in the Silurian area. The Triassic clay furnishes excellent bricks. Eskers or glacial ridges occur at several places. The limestone is not only abundant and good, but from the position of the rocks it can be obtained at small expense in working. Freestone and slates are quarried in considerable quantities. The soil in the more level portions of the county is fertile where it rests on limestone, and there is also a mixed soil of deep clay, which is capable of high cultivation; but in the hilly regions a strong retentive clay prevails, which could be made productive only by careful draining and culture. Spade husbandry generally prevails. The proportion of tillage to pasturage is roughly as 1 to 1½. Oats, potatoes and turnips are the principal crops, but the quantity grown decreases. The number of cattle, sheep, pigs, goats and poultry, on the other hand, increases or is well maintained. Linen is the only manufacture of consequence, but the cultivation of flax has almost died out. The Belfast and Clones line of the Great Northern railway crosses the county from north-east to west, passing the town of Monaghan, and the Dundalk and Clones line of the same company runs from south-east to west, with branches to Carrickmacross and to Cootehill (county Cavan).

The population (86,206 in 1891; 74,611 in 1901) decreases as rapidly as any county population in Ireland, and emigration is very heavy. The total includes about 73% of Roman Catholics, and about 12% each of Protestant Episcopalians and of Presbyterians. The principal towns are Monaghan (the county town, pop. 2932), Clones (2068), Carrickmacross (1874), Castleblayney (1576) and Ballybay (1208). The county includes five baronies. Assizes are held at Monaghan, and quarter sessions at Carrickmacross, Castleblayney, Clones and Monaghan. The two county members sit for the north and south divisions respectively. The county is in the Protestant and Roman Catholic dioceses of Clogher.

The district now called the county Monaghan was included in the district of Uriel or Orgial, and long known as Macmahon's country. It was made shire ground under its present name by Sir John Perrot in the reign of Elizabeth. At Clones there is a round tower in good preservation, but very rude in its masonry, another at Inishkeen is in ruins. Near Clones there are two large raths. Although there are several Danish forts there are no medieval castles of importance The only monastic structure of which any vestiges remain is the abbey of Clones, which was also the seat of a bishopric. The abbey dates from the 6th century, but was rebuilt in the 14th century after destruction by fire.

MONAGHAN, a market town and the county town of county Monaghan, Ireland, on the Ulster Canal and the Belfast and Clones line of the Great Northern railway, by which it is 52 m. S.W. by W. of Dublin. Pop (1901), 2932. There is a modern Roman Catholic cathedral (1862–1892) for the diocese of Clogher, a convent of the Sisters of St Louis, and a Protestant church (1836), and the public and county buildings include court-house, gaol, workhouse, asylum, hospital and barracks. Educational establishments include a national model school and the college of St Macartan, preparatory for the Roman Catholic priesthood. The town takes its name (Muinechan, the town of monks) from an early monastery. It was incorporated by James I., but was little more than a hamlet until the close of the 18th century. Rossmore Park, the fine demesne of Lord Rossmore, is the most noteworthy of several neighbouring residences. The town is governed by an urban district council.

MONA MONKEY, a West African representative of the group of monkeys generally known as guenons, and scientifically as *Cercopithecus*. The mona (*C. mona*) typifies a sub-genus of the same name (*Mona*) characterized, among other features, by the presence of a black band running from the angle of each eye to the ear. In the mona itself the general colour of the upper parts is black, with a pair of oval white spots near the root of the tail, while a band across the forehead and the whole under surface are likewise white. (See PRIMATES.)

MONARCHIANISM, a theological term designating the view taken by those Christians who, within the Church, towards the end of the 2nd century and during the 3rd, opposed the doctrine of an independent personal subsistence of the Logos. During the middle of the 2nd century a number of varying christological views began to germinate, growing for a time side by side. They fall into two great classes: (*a*) Christ was a man in whom the Spirit of God had dwelt; (*b*) Christ was the Divine Spirit who had assumed flesh. Each class based its position on Scripture, but the latter (which prevailed) had the advantage of being able easily to combine with cosmological and theological propositions current in the religious philosophy of the time. The opposition to it arose out of a fear that it threatened monotheism. The representatives of the extreme monotheistic view, which while regarding Christ as Redeemer, clung tenaciously to the numerical unity of the Deity, were called Monarchians, a term brought into general use by Tertullian It has to be remembered (1) that the movement originated within the pale of the Church, and had a great deal in common with that which it opposed; (2) that it was ante-Catholic rather than anti-Catholic, *e.g.* the Canon of the New Testament had not yet been established. It is usual to speak of two kinds of monarchianism—the dynamistic and the modalistic, though the distinction cannot be carried through without some straining of the texts. By monarchians of the former class Christ was held to be a mere man, miraculously conceived indeed, but constituted the Son of God simply by the infinitely high degree in which he had been filled with Divine wisdom and power. This view was represented in Asia Minor about the year 170 by the anti-Montanistic Alogi, so called by Epiphanius on account of their rejection of the Fourth Gospel it was also taught at Rome about the end of the 2nd century b Theodotus of Byzantium, a currier, who was excommunicate by Bishop Victor, and at a later date by Artemon, excommunicated by Zephyrinus About the year 260 it was again propounded within the Church by Paul of Samosata (*q.v.*), who hel that, by his unique excellency, the man Jesus gradually rose t the Divine dignity, so as to be worthy of the name of God Modalistic monarchianism, conceiving that the whole fullnes of the Godhead dwelt in Christ, took exception to the "subordinatianism" of some Church writers, and maintained that th names Father and Son were only two different designations o the same subject, the one God, who "with reference to the relations in which He had previously stood to the world is called th Father, but in reference to His appearance in humanity is calle the Son." It was first taught, in the interests of the "monarchia" of God, by Praxeas, a confessor from Asia Minor, i Rome about 190, and was opposed by Tertullian in his well known controversial tract. The same view—the "patripassian as it was also called, because it implied that God the Father ha suffered on the cross—obtained fresh support in Rome about 21 from certain disciples of Noetus of Smyrna, who received modified support from Bishop Callistus. It was on this accoun that Hippolytus, the champion of hypostasian subordinatianism along with his adherents, withdrew from the obedience o Callistus, and formed a separate community. In Carthag Praxeas for a time had some success, but was forced by Tertullian not only to desist but to retract. A new and conciliator phase of patripassianism was expounded at a somewhat late date by Beryllus of Bostra, who, while holding the divinity o Christ not to be *ἰδία*, or proper to Himself, but *πατρική* (belongin to the Father), yet recognized in His personality a new *πρόσωπο* or form of manifestation on the part of God. Beryllus, howeve was convinced of the wrongness of this view by Origen (*q.v.* and recanted at the synod which had been called together i 244 to discuss it. (For the subsequent history of modalisti monarchianism see SABELLIUS.)

See the Histories of Dogma by A. Harnack, F. Loofs, R. Seeberg also R. L. Ottley, *The Doctrine of the Incarnation.*

MONARCHY (Fr. *monarchie*, from Lat. *monarchia*, G *μοναρχία*, rule of one, *μόνος*, alone, *ἀρχή*, rule), strictly, th undivided sovereignty or rule of a single person. Hence th term is applied to states in which the supreme authority vested in a single person, the monarch, who in his own righ is the permanent head of the state. The character of tr monarchy is well defined in the well-known lines of Cowp (*Verses supposed to be written by Alexander Selkirk*):

> "I am monarch of all I survey,
> My right there is none to dispute."

The word "monarchy" has, however, outlived this origin meaning, and is now used, when used at all, somewhat loosel of states ruled over by hereditary sovereigns, as distinct fro republics with elected presidents; or for the "monarchic principle," as opposed to the republican, involved in this di tinction.

The old idea of monarchy, viz. that of the prince as represen ing within the limits of his dominions the monarchy of God ov all things, culminated in the 17th century in the doctrine of t divine right of kings, and was defined in the famous dictum Louis XIV.: *L'état c'est moi!* The conception of monarchy w derived through Christianity from the theocracies of the East; was the underlying principle of the medieval empire and al of the medieval papacy, the rule of the popes during the peri of its greatest development being sometimes called "the pap monarchy." The monarchical principle was shaken to i foundations by the English revolution of 1688; it was shatter by the French revolution of 1789; and though it survives as political force, more or less strongly, in most European countrie "monarchists," in the strict sense of the word, are everywhere small and dwindling minority. To express the change phras were invented which have come into general use, thou involving a certain contradiction in terms, viz. "limited" constitutional monarchy," as opposed to "absolute" or autocratic monarchy."

Finally, a distinction is drawn between "elective" and hereditary" monarchies. Of the former class the most nspicuous was the Holy Roman Empire; but in Europe all onarchies were, within certain limits, originally elective; and, ter the introduction of Christianity, the essential condition the assumption of sovereign power was not so much kinship ith the reigning family as the "sacring" by the divine thority of the Church. The purely hereditary principle ıs of comparatively late growth, the outcome of obvious nvenience, exalted under the influence of various forces into religious or quasi-religious dogma. (See also GOVERNMENT d SOVEREIGNTY.)

MONASSIR (MONASIR), an African tribe of Semitic stock, ring in the Nile valley (Berber mudiria) between Birti (their adquarters) and Dar Robatab. They are a prosperous, dentary tribe, claim kinship with the Ababda, and speak abic, but are of very mixed blood. Next to Birti their ief settlement is at Salamat. Both places are on the left nk of the Nile. It was by Monassir tribesmen that Colonel D. H. Stewart, Gordon's comrade at Khartum, was murred in 1884.

MONASTICISM (Gr. *μοναστικός*, living alone, *μόνος*), a system living which owes its origin to those tendencies of the human ul which are summed up in the terms "asceticism" and mysticism." Mysticism may broadly be described as the fort to give effect to the craving for a union of the soul with the eity already in this life; and asceticism as the effort to give fect to the hankering after an ever-progressive purification of e soul and an atoning for sin by renunciation and self-denial things lawful. These two tendencies may well be said to be neral instincts of humanity; because, though not always lled into activity, they are always liable to be evoked, and in ages and among all races they frequently have asserted themlves. (See ASCETICISM and MYSTICISM.) Indeed the history of ligion shows that they are among the most deep-rooted and despread instincts of the human soul; and monasticism is e attempt to develop and regulate their exercise. Thus onasticism is not a creation of Christianity; it is much der, and before the Christian era a highly organized onasticism existed in India. (See the articles on BRAHMANISM; UDDHISM; and LHASA.)

1. *Pre-Christian Monasticism.*—Greek asceticism and mystism seem never to have produced a monastic system; but among e Jews, both in Judaea and in Alexandria, this development ok place. In Judaea the Essenes before the time of Christ ed a fully organized monastic life (see Schürer, *Jewish People*, § 30); and the same is true in regard to the Therapeutae in e neighbourhood of Alexandria (the authenticity of Philo's *e Vita contemplativa*, which describes their manner of life, is ain recognized by scholars).

A general sketch of pre-Christian asceticism and monasticism, th indication of the chief authorities, is given in O. Zöckler's *skese und Mönchtum* (1897), pp. 32–135. This account is epitoized by J. O. Hannay, *Spirit and Origin of Christian Monasticism* 903), app. i: the view now common among scholars is there aintained, that these pre-Christian realizations of the monastic ea had little, and indeed no, influence on the rise and development Christian monasticism.

2. *Beginnings of Christian Monasticism.*—The practice of ceticism asserted itself at an early date in Christian life: men d women abstained from marriage, from flesh meat, from the e of intoxicating drink, and devoted themselves to prayer, ligious exercises and works of charity (S. Schiwietz, *Das orgenländische Mönchtum*, 1904, pt. i.; J. O. Hannay, *op. cit.* s. 2, 3). This they did in their homes, without withdrawing om their families or avocations. In time, however, the tenncy to withdraw from society and give oneself up wholly to e practice of religious and ascetical exercises set in; and at any te in Egypt, at the middle of the 3rd century, it was the custom r such ascetics to live in solitary retirement in the neighbourod of the towns and villages. This was the manner of life which St Anthony (*q.v.*) began to lead, *c.* 270; but after fifteen years he withdrew to a deserted fort on the east bank of the Nile, opposite the Fayum. Here he enclosed himself and led a life cut off from all intercourse with man. There are reasons for doubting that Anthony was the first Christian hermit: probably there is some historical foundation for the tradition that one of those who fled to the desert in the Decian persecution continued to dwell in a cave by the shore of the Red Sea, unknown to men, till visited by St Anthony long years afterwards (see E. C. Butler, *Lausiac History of Palladius*, 1898, pt. i. p. 230). But this was a single case which does not affect the fixed tradition of monastic Egypt in the 4th century that Anthony was the father of Christian monachism.

During twenty years Anthony lived a life of seclusion, never coming forth from his fort, never seeing the face of man. But his fame went abroad and a number of would-be disciples came and took up their abode in the caves and among the rocks that surrounded his retreat, and called on him to guide them in the path of life they had chosen. In response to these appeals Anthony came forth and set himself to organize the life of the multitude of ascetics that had grown up around him. This act, which took place in the first years of the 4th century, must be regarded as the inauguration of Christian monachism.

3. *St Anthony's Monachism.*—The form of monastic life directly derived from St Anthony was the type that prevailed in middle and northern Egypt up to the middle of the 5th century. The chief authorities for the study of this type of monastic life are the *Vita Antonii* (probably by Athanasius), the *Historia monachorum* (ed. E. Preuschen), the *Historia lausiaca* of Palladius (ed. E. C. Butler)—these works are to be found in Latin in Rosweyd's *Vitae Patrum* (*Migne, Patrol Lat.* LXXIII., LXXIV.)—and the writings of Cassian (English translation by Gibson in "Nicene and Post-Nicene Library"). A generation ago all this literature was in disrepute; but it has been revindicated, and its substantially historical character is now recognized on all hands (see E. C. Butler, *op. cit.* pt. ii. § 1).

Antonian monachism grew out of the purely eremitical life, and it retained many of the characteristic features inherited from its origin. The party of travellers whose journey in 394 is narrated in the *Historia monachorum* found at the chief towns along the Nile from Lycopolis (Assiut or Siut) to Alexandria, and in the deserts that fringed the river, monastic habitations, sometimes of hermits, sometimes of several monks living together but rather the life of hermits than of cenobites. It is at the great monastic settlements of Nitria and Scete that we are best able to study this kind of Egyptian monasticism. Here in one portion of the desert, named Cellia, the monks lived a purely eremitical life; but in Nitria (the Wadi Natron) they lived either alone, or two or three together, or in communities, as they preferred. The system was largely voluntary; there was no organized community life, no living according to rule, as it is now understood. In short the life continued to be semi-eremitical. (See Butler, *op. cit.* pt. i. p. 233; Hannay, *op. cit.* chs. 4, 5; Schiwietz, *op. cit.* pt. ii. §§ 1–11.)

4. *St Pachomius's Monachism.*—Very different was the type of monastic life that prevailed in the more southerly parts of Egypt. Here, at Tabennisi near Dendera, about 315–320, St Pachomius (*q.v.*) established the first Christian cenobium, or monastery properly so called. (On St Pachomius and his monastic institute see P. Ladeuze, *Cénobitisme Pakhomien* (1898); Schiwietz, *op. cit.* pt. ii. §§ 12–16; E. C. Butler, *op. cit.* pt. i. p. 234, pt. ii. notes 48, 49, 54, 59). Before his death in 346 Pachomius had established nine monasteries of men and one of women, and after his death other foundations continued to be made in all parts of Egypt, but especially in the south, and in Abyssinia. Palladius tells us that *c.* 410 the Pachomian or Tabennesiot monks numbered some seven thousand. The life was fully cenobitical, regulated in all details by minute rules, and with prayer and meals in common. As contrasted with the Antonian ideal, the special feature was the highly organized system of work, whereby the monastery was a sort of agricultural and industrial colony. The work was an integral part

of the life, and was undertaken for its own sake and not merely for an occupation, as among the Antonian monks. This marks a distinctly new departure in the monastic ideal.

In another respect too St Pachomius broke new ground: not only did he inaugurate Christian cenobitical life, but he also created the first "Religious Order." The abbot of the head monastery was the superior-general of the whole institute; he nominated the superiors of the other monasteries; he was visitor and held periodical visitations at all of them; he exercised universal supervision, control and authority; and every year a general chapter was held at the head house. This is a curious anticipation of the highly organized and centralized forms of government in religious orders, not met with again till Cluny, Citeaux, and the Mendicant orders in the later middle ages.

A passing reference should be made to the Coptic abbot Shenout, who governed on similar lines the great "White Monastery," whereof the ruins still survive near Akhmim; the main interest of Shenout's institute lies in the fact that it continued purely Coptic, without any infiltration of Greek ideas or influence. (See J. Leipoldt, *Schenute von Atripe*, 1903.)

Egyptian monachism began to wane towards the end of the 5th century, and since the Mahommedan occupation it has ever been declining. Accounts of its present condition may be found in R. Curzon's *Monasteries of the Levant* (1837), or in A. J. Butler's *Ancient Coptic Churches* (1884). Hardly half a dozen monasteries survive, inhabited by small and ever dwindling communities.

5. *Oriental Monachism.*—The monastic institute was imported early in the 4th century from Egypt into Syria and the Oriental lands. Here it had a great vogue, and under the influence of the innate Asiatic love of asceticism it tended to assume the form of strange austerities, of a kind not found in Egyptian monachism in its best period. The most celebrated was the life of the Stylites or pillar hermits (see SIMEON STYLITES). Monastic life here tended to revert to the eremitical form, and to this day Syrian and Armenian monks are to be found dwelling in caverns and desert places, and given up wholly to the practice of austerity and contemplation (see E. C. Butler, *Lausiac History of Palladius*, pt. i. p. 239, where the chief authorities are indicated). Before the close of the 4th century monachism spread into Persia, Babylonia and Arabia.

6. *Basilian and Greek Monachism.*—Though Eustathius of Sebaste was the first to introduce the monastic life within the confines of what may be called Greek Christianity in Asia Minor (*c.* 340), it was St Basil who adapted it to Greek and European ideas and needs. His monastic legislation is explained and the history of his institute sketched in the article BASILIAN MONKS. Here it will suffice to say that he followed the Pachomian rather than the Antonian model, setting himself definitely against the practice of the eremitical life and of excessive asceticism, and inculcating the necessity and superiority of labour. The lines laid down by St Basil have continued ever since to be the lines in which Greek and Slavonic monasticism has rested, the new multitudinous modifications of the monastic ideal, developed in such abundance in the Latin Church, having no counterpart in the Greek. But the element of work has decreased, and Greek and Slavonic monks give themselves up for the most part to devotional contemplation.

7. *Early Western Monachism.*—The knowledge of the monastic life was carried to western Europe by St Athanasius, who in 340 went to Rome accompanied by two monks. The *Vita Antonii* was at an early date translated into Latin and propagated in the West, and the practice of monastic asceticism after the Egyptian model became common in Rome and throughout Italy, and before long spread to Gaul and to northern Africa. A *résumé* of the chief facts will be found in E. C. Butler, *op. cit.* pt. i. p. 245; see also Hannay, *op. cit.* ch. 7. The monastic ideals prevalent were those of the Antonian monachism, with its hankering after the eremitical life and the practice of extreme bodily austerities. But climatic conditions and racial temperament rendered the Oriental manner of monasticism unattainable, as a rule, in the West. Hence it came to pass that by the end of the 5th century the monastic institute in western Europe, and especially in Italy, was in a disorganized condition, sinking under the weight of traditions inherited from the East. It was St Benedict who effected a permanently working adaptation of the monastic ideal and life to the requirements and conditions of the western races.

8. *St Benedict's Monachism.*—St Benedict (*c.* 500) effected his purpose by a twofold break with the past: he eliminated from the idea of the monastic life the element of Oriental asceticism and extreme bodily austerity; and he put down the tendency, so marked in Egypt and the East, for the monks to vie with one another in ascetical practices, commanding all to live according to the rule. The life was to be self-denying and hard, but not one of any great austerity (for details see BENEDICT OF NURSIA; and E. C. Butler, *op. cit.* pt. i. pp. 237 and 251). The individual monk was sunk in the community whose corporate life he had to live. St Benedict's rule was a new creation in monastic history; and as it rapidly supplanted all other monastic rules in western Europe, and was for several centuries the only form of monasticism in Latin Christianity (outside of Ireland), it is necessary to speak in some little detail of its spirit and inner character.[1] It has to be emphasized at the outset that the monasteries in which the Benedictine rule was the basis of the life did not form a body or group apart within the great "monastic order," which embraced all monasteries of whatever rule; nor had Benedictine monks any special work or object beyond that common to all monks—viz. the sanctifying of their souls by living a community life in accordance with the Gospel counsels. St Benedict defines his monastery as "a school of the service of the lord" (*Reg.*, *Prol.*). The great act of service is the public common celebration of the canonical office, the "work of God" he calls it, to which "nothing is to be preferred" (*Reg.* c. 43). The rest of the day is filled up with a round of work and reading. Work, and in St Benedict's time it was predominantly field work, took an even more recognized and integral place in the life than was the case under St Pachomius or St Basil, occupying notably more time than the church services. St Benedict introduced too into the monastic life the idea of law and order, of rule binding on the abbot no less than on the monks; thus he reduced almost to a vanishing point the element of arbitrariness, or mere dependence on the abbot's will and whim, found in the earlier rules. Lastly, he introduced the idea of stability, whereby monk and community were bound to each other for life, the normal thing for the Benedictine being to live and die in the monastery of his profession: thus the power hitherto enjoyed by monks, of wandering from monastery to monastery, was cut away, and the Benedictine community was made into a family whose members were bound to one another by bonds that could not be severed at will.

9. *Western Monachism in the Early Middle Ages.*—It is easy to understand that a form of monastic life thus emptied of distinctively Oriental features and adapted to the needs of the West by a great religious genius like St Benedict, should soon have distanced all competitors and have become the only monastic rule in western Europe. The steps in the propagation of the Benedictine rule are traced in the article BENEDICTINES. The only serious rival was the Irish rule of Columban; and here it will be in place to say a word on Irish monasticism, which, in its birthplace, stood aloof to the end from the general movement The beginnings of Celtic monachism are obscure, but it seems to have been closely connected with the tribal system.[2] When however, Irish monachism emerges into the full light of history it was in its manifestations closely akin to the Egyptian, or even to the Syrian type: there was the same love of the eremitical life, the same craving after bodily austerities of an extraordinary kind, the same individualistic piety. The Irish monks were great missioners in the north of England and the northern and

---

[1] This topic is dealt with by F. A. Gasquet, *Sketch of Monastic Constitutional History* (pp. viii.–xxii.), the Introduction to 2nd edition of the translation of Montalembert's *Monks of the West* (1895).

[2] See Willis Bund, *Celtic Church in Wales* (1897); H. Zimmer, art "Keltische Kirche" in Herzog-Hauck, *Realencyklopädie* (3rd ed.) translated into English by Kuno Meyer (1902).

central parts of Europe, and in the course of the 7th century the Irish rule of St Columban and the Roman rule of St Benedict met in the monasteries in central Europe that had been founded by Columban and his Irish monks. The Benedictine rule supplanted the Irish so inevitably that the personnel ceased to be Irish, that even in St Columban's own monastery of Luxeuil his rule was no longer observed, and by Charlemagne's time all remembrance of any other monastic rule than the Benedictine had died out.

During the 7th and 8th centuries the Benedictine houses were the chief instrument in the christianizing, civilizing and educating of the Teutonic races. In spite of the frequent pillage and destruction of monasteries by Northmen, Saracens, Arabs and other invaders; in spite of the existence of even widespread local abuses, St Benedict's institute went on progressing and consolidating; and on the whole it may be said that throughout the early middle ages the general run of Benedictine houses continued to perform with substantial fidelity the religious and social functions for which they were created.

10. *Offshoots and Modifications of Benedictine Monachism: the Rise of "Orders."*—Up to the beginning of the 10th century we do not meet in the West such a thing as an "order"—an organized corporate body composed of several houses, diffused through various lands, with centralized government and objects and methods of its own. As stated above, St Pachomius's monasteries formed an order—a curious anticipation of what six centuries later was to become the vogue in Western monasticism. The Benedictine houses never coalesced in this manner; even when, later on, a system of national congregations was introduced, they were but loose federations of autonomous abbeys; so that to this day, though the convenient expression "Benedictine order" is frequently used, the Benedictines do not form an order in the proper sense of the word. But with the 10th century we reach the period of orders, and it is on this line that all subsequent developments in Western monasticism have run.

The first order was that of Cluny, founded in 910; in rule and manner of life it continued purely Benedictine, and it wielded extraordinary power and religious influence up to the middle of the 12th century. (See CLUNY.)

The chief offshoot from the Benedictine institute were the Cistercians (*c.* 100); their ground idea was a return to the letter of St Benedict's rule, and a reproduction, as close as could be, of the exterior conditions of life as they existed in St Benedict's own monastery; consequently field work held a prominent place in the Cistercian ideal. This ideal it has not been possible permanently to maintain in the great body of the order, but only in limited circles, as Trappists (*q.v.*). But for a century (1125–1225) Citeaux supplanted Cluny as the spiritual centre of western Europe. The Cistercians were an organized, centralized order in the full sense of the word. (See CISTERCIANS.)

Towards the end of the 10th century and during the 11th a strong tendency set in to revert to the eremitical life, probably owing to the example of the Greek monks, who at this time entered Sicily and south Italy in great numbers. This tendency produced the orders of the Camaldulians or Camaldolese (*c.* 975) in Italy, and in France the Grandmontines (1076) and Carthusians (1084), all leading practically eremitical lives, and assembling ordinarily only for the church services. The Vallombrosians (1038) near Florence maintained a cenobitical life, but eliminated every element of Benedictine life that was not devoted to pure contemplation. At Fontevrault (founded in 1095) the special feature was the system of "double monasteries" *i.e.* neighbouring, but rigorously separated, monasteries of men and of women—the government being in the hands of the abbesses.

In all these lesser orders may be discerned the tendency of a return to the elements of Eastern monasticism discarded by St Benedict—to the eremitical life; to the purely contemplative life with little or no factor of work; to the undertaking of rigorous bodily austerities and penances—it was at this time that the practice of self-inflicted scourgings as a penitential exercise was introduced. All this was a reaction from St Benedict's reconstruction of the monastic life—a reaction which in the matter of austerities and individualistic piety has made itself increasingly felt in the later manifestations of the monastic ideal in the West.

11. *New Kinds of Religious Orders.*—Up to this point we have met only with monasticism proper; and if the term were taken strictly, the remainder of this article would be concerned only with the later history of the institutes already spoken of; for neither canons regular, friars, nor regular clerks, are in the strict sense monks. But it is usual, and it will be convenient here, to use the term monasticism in a broader sense, as equivalent to the technical "religious life," and as embracing the various forms that have come into being so prolifically in the Latin Church at all periods since the middle of the 11th century.

The first of these new forms was that of the canons regular or Augustinian canons (*q.v.*) who about the year 1060 arose out of the older semi-monastic canonical institute, and lived according to the so-called "Rule of St Augustine." The essential difference between monks and regular canons may be explained as follows: monks, whether hermits or cenobites, are men who live a certain kind of life for its own sake, for the purpose of leading a Christian life according to the Gospel's counsel and thus serving God and saving their own souls; external works, either temporal or spiritual, are accidental; clericature or ordination is an addition, an accession, and no part of their object, and, as a matter of fact, till well on in the middle ages it was not usual for monks to be priests; in a word, the life they lead is their object, and they do not adopt it in order the better to compass some other end. But canons regular were in virtue of their origin essentially clerics, and their common life, monastery, rule, and the rest, were something additional grafted on to their proper clerical state. The difference manifested itself in one external point: Augustinian canons frequently and freely themselves served the parish churches in the patronage of their houses; Benedictine monks did so, speaking broadly, hardly at all, and their doing so was forbidden by law, both ecclesiastical and civil. In other respects the life of canons regular in their monasteries, and the external policy and organization among their houses, differed little from what prevailed among the Black Benedictines; their superiors were usually provosts or priors, but sometimes abbots. As contrasted with the friars they are counted among the monastic orders. Alongside of the local federations or congregations of houses of Augustinian canons were formed the Premonstratensian order (1120) (*q.v.*), and the English "double order" of St Gilbert of Sempringham (1148) (*q.v.*), both orders, in the full sense of the word, composed of Augustinian canons.

Two special kinds of orders arose out of the religious wars waged by Christendom against the Mahommedans in the Holy Land and in Spain: (1) the Military orders: the Knights Hospitallers of St John and the Knights Templars, both at the beginning of the 12th century, and the Teutonic Knights at its close; (2) the orders of Ransom, whose object was to free Christian prisoners and slaves from captivity under the Mahommedans, the members being bound by vow even to offer themselves in exchange; such orders were the Trinitarians (*q.v.*) founded in 1198, and the order of Our Lady of Ransom (de Mercede), founded by St Peter Nolasco in 1223; both were under the Augustinian rule.

At the beginning of the 13th century arose the series of great Mendicant orders. Their nature and work and the needs that called them into being are explained in the article MENDICANT MOVEMENT, and in the separate articles on ST FRANCIS OF ASSISI and FRANCISCANS (1210), ST DOMINIC and DOMINICANS (1215), CARMELITES (1245), AUGUSTINIAN HERMITS (1256)—these were the four great orders of Mendicant friars—to them were added, in 1487, the Servites (*q.v.*) founded in 1233.

It will be in place here to explain the difference between friars, monks, and canons regular. The distinction between the two last has already been brought out; but they agree in this that the individual monk and canon alike belongs to his house of profession and not to any greater or wider corporation. They are bound by place and the unit is the individual community. Thus among monks and canons regular each monastery has its own fixed community, which is in a real sense a family; and the monk or canon, no matter where he may be, looks on his monastery as his "home," like the ancestral home of a great family. With the friars this is all changed: the friar does not belong to any particular house, but to the province or order, so that there is no reason, beyond the command of his superiors, why he should be living in one house rather than another. In the monk attachment to his own one monastery is a virtue; in the friar detachment is the ideal. The monk, or the canon, normally exercises his influence on the world in and through his community, not as an individual but as a member of a corporate body. The friar's sphere of work is normally outside his convent, and he works and influences directly and as an individual. Lastly, in regard to the object aimed at there was an important difference, for the professed object of the friars was to be clerical helpers of the parochial clergy in meeting the specifically religious needs of the time. Already, in St Francis's lifetime, his friars had grown into an order dedicated to spiritual ministrations among the poor, the sick, the ignorant, the outcasts of the great cities; while by the very conception of their institute the Dominicans were dedicated to the special work of preaching, especially to heretics and heathens. Here, too, should be mentioned St Francis's other great creation, the Tertiaries (*q.v.*), or devout men and women living in the world, who while continuing their family life and their ordinary avocations, followed a certain rule of life, giving themselves up to more than ordinary prayer and the pursuit of good works, and abstaining from amusements of a worldly kind.

12. *The Religious Orders in the Later Middle Ages.*—The 13th century was the heyday of monasticism in the West; the Mendicant orders were in their first fervour and enthusiasm; the great abbeys of Benedictines, Cistercians and Augustinian canons reflected the results of the religious reform and revival associated with Hildebrand's name, and maintained themselves at a high and dignified level in things religious and secular; and under the Benedictine rule were formed the new congregations or orders of Silvestrines (1231), Celestines (*c.* 1260) and Olivetans (1319), which are described under their several headings. But towards the end of the century a period of decline set in, which ran its course in increasing volume throughout the 14th century. A great wave of secularity rolled over the Church, engulfing the religious orders with the rest; love waxed cold, fervour languished, learning declined, discipline was relaxed, bitter rivalries broke out, especially between Franciscans and Dominicans. The great schism was reflected in the Mendicant orders which were divided into two obediences, to the destruction of discipline. The great wealth of the old monastic orders exposed them, especially in France and Italy, to the vicious system of commendation, whereby a bishop, an ecclesiastic, or even a layman was appointed "commendatory abbot" of a monastery, merely for the purpose of drawing the revenues (see ABBOT); the monasteries were often deprived even of necessary maintenance, the communities dwindled, and regular observance became impossible. There is reason to believe that in England a relatively good level was maintained throughout, thanks in great measure to the fact that the kings resolutely refused to allow the introduction of commendation—Wolsey was the first and last commendatory abbot in England. In the German lands, the lowest level was touched, and the writings of the Augustinian canon Johann Busch, and of the Benedictine abbot Trithemius reveal a state of things in the first half of the 15th century that urgently called for reform. The first move in this direction was made in the Netherlands and north Germany under the influence of Gerhard Groot (*q.v.*), and issued in the formation of the Windesheim congregation of Augustinian canons and the secular congregation of Brothers of Common Life (*q.v.*) founded *c.* 1384, both of which became centres of religious revival. During the first half of the 15th century numerous and effective efforts at reform were initiated in all the orders without exception, and in every part of Europe. These movements, promoted by the councils of Constance and Basel, partook of the spirit of the time and were characterized by an extreme austerity of life and a certain hardness of spirit, and a sort of police regulation easily understandable at a time of reaction from grave abuses. At this time arose the Hieronymites (*q.v.*) founded in 1375, under the Augustinian rule, the Observants (1415) among the Franciscans (*q.v.*), and the Minims (founded *c.* 1460 by St Francis of Paola, *q.v.*), whose programme was to outdo the Minors or Franciscans. These various reform movements among the orders were widely but not universally successful; and so the Reformation found religious houses in an unsatisfactory state in sufficient numbers to afford the reformers one of their chief handles against the old religion. The Reformation and the religious wars that followed in its wake destroyed the monasteries and religious orders of all kinds in northern Europe and crippled them in central Europe.

13. *The Modern Orders.*—During the Reformation period there sprang up, to meet the needs of the time, a new kind of religious order, called Regular Clerks. These are religious orders in the full sense of the word, as the members take the solemn religious vows. Regular clerks are by their institute clerics and priests, and they are devoted to some particular work or works as their own special object—as education, the preaching of missions and retreats, or the going on missions to the heathen. They carry still further the tendencies that differentiate the friars from the monks; and in particular, in order to be more free in devoting themselves to their special works, the orders of regular clerks have commonly given up the choral celebration of the canonical office, which had been maintained by the friars.

Of regular clerks by far the most important are the Jesuits (*q.v.*), founded in 1540; there are also the Theatines (founded 1524 by St Cajetan and Caraffa, afterwards Paul IV.); the Barnabites (founded 1530, by St Antonio Zaccaria) and others (see Max Heimbucher, *Orden u. Kongregationen* (1897), II., §§ 108–114). Strictly speaking the "religious congregations" should be distinguished from the orders of regular clerks, the difference being that in the former the vows, though taken for life, are only "simple vows" and more easily dispensable by authority; but the character and work of the two institutes is very similar. The chief of these congregations are the Passionists (founded by St John of the Cross, 1725) and the Redemptorists (founded by St Alfonsus Liguori, 1749), both dedicated to giving missions and retreats. The Christian Brothers, devoted to primary education, founded by St Jean Baptiste de la Salle in 1679, are not in orders (Heimbucher, *op. cit.* §§ 115–118).

Besides the religious congregations there are a number of "secular congregations," composed of secular priests living together under temporary vows and free to leave at will; the following deserve mention: Oblates of St Charles (founded by St Charles Borromeo, 1578); Oratorians (founded by St Philip Neri, *c.* 1570); the French Oratory (founded by Cardinal Berulle, 1613), a similar but distinct institution, which produced a number of scholars of the highest distinction—Thomassin, Morin, Marlebranche, Richard Simon, Juénin, Lebrun, Masillon, and others; Lazarists (founded by St Vincent de Paul, 1624); Sulpicians (founded by M. Olier, 1642), and a vast number of others, including several for the mission to the heathen (see Heimbucher *op. cit.* §§ 124–140).

During the period under review, from the Reformation to the French Revolution, the old orders went on alongside of the new, and many notable revivals and congregations arose among them: the most noteworthy were the Capuchins (*q.v.*) among the Franciscans (1528); the Discalced Carmelites (*q.v.*) of St Teresa and St John of the Cross (1562); the Trappists (*q.v.*) among the Cistercians (1663); and, most famous of all, the Maurists (*q.v.*) among the Benedictines of France (1621).

14. *The Religious Orders in Recent Times.*—At the end of the 18th century and the opening of the 19th the religious orders received a succession of blows in those countries in which they had survived the Reformation from which they have only

in the present generation recovered. The Jesuits were suppressed by Pope Clement XIV. in 1773, and restored by Pius VII. in 1814. As the result of the ecclesiastical policy of the emperor Joseph II. nearly all religious houses of all kinds were suppressed throughout the Austrian dominions (1780). The French Revolution swept them out of France and caused the secularization of the great majority in central Europe and Italy. In Portugal and Spain they were dissolved in 1834–1835; in Italy in 1866; in the Prussian dominions in 1871. The last half of the 19th century, and more especially the last quarter, witnessed a remarkable revival of vitality and growth in most of the older orders in nearly every country of western Europe, and besides, an extraordinary number of new congregations, devoted to works of every sort, were founded in the 19th century: Heimbucher (*op. cit.*, §§ 118, 134–140) numbers no fewer than seventy of these new congregations of men. In the new countries, especially in the United States and Australia, but also in South Africa, orders and congregations of all kinds are most thriving. The chief set-back has come again in France, where, by the Association Laws of 1903, the religious orders have nearly all been suppressed and expelled and their property confiscated.

15. *The Nuns.*—In the foregoing sketch nothing has been said concerning the nuns; and yet in all ages women, hardly less than men, have played their part in monasticism. In the earliest Christian times the veiled virgins formed a grade or order apart, more formally separated from the community than were the male ascetics. There is reason for believing that there were organized convents for women before there were any for men; for when St Anthony left the world in 270 to embrace the ascetic life, the *Vita* says he placed his sister in a nunnery (*παρθενών*). We learn from Palladius that by the end of the 4th century nunneries were numerous all over Egypt, and they existed also in Palestine, in Italy and in Africa—in fact throughout the Christian world. It is a curious coincidence that the sister of each of the three great cenobitical founders, Pachomius, Basil and Benedict, was a nun and ruled a community of nuns according to an adaptation of her brother's rule for monks. In the West the Benedictine nuns played a great part in the Christian settlement of north-western Europe. As the various monastic and mendicant orders arose, a female branch was in most cases formed alongside of the order; and so we find canonesses, and hermitesses, and Dominicanesses, and Franciscan nuns [or Clares (*q.v.*)]—requisite information will be found in the respective articles. Then there were the "double orders" of Sempringham (see St Gilbert) and Fontevrault, in which the nuns were the predominant, or even the dominant, element. Of the modern orders of men only a few include nuns. But on the other there are a vast number of purely female orders and congregations. The great majority of these modern congregations of women follow the Augustinian rule, supplemented by special constitutions or by-laws; such are the Brigittines, the Ursulines and the Visitation nuns: others follow the rule of the third order of the Franciscans or other Mendicants (see Tertiaries). In early times nuns could go out of their enclosure on occasion; but in the later middle ages, up to the council of Trent, the tendency was to keep them more and more strictly confined within their convent precincts. In 1609 an English lady, Mary Ward, founded at Munich the "Institute of Mary," the nuns of which were not bound to enclosure. This new departure, or rather, return to old ideas, encountered vehement opposition and difficulties that nearly wrecked it; but it has survived, and has been the pioneer in the extraordinary development of institutes of women devoted to external good works of every kind. St Vincent of Paul soon followed; in 1633 he established the Sisters of Charity, bound only by yearly vows, and wholly given up to works of charity—chiefly nursing in hospitals and in the homes of the poor, and primary education in poor schools.

As women are debarred from exercising the spiritual functions of the ministry, it follows that nuns have to devote themselves either to a more purely contemplative life, or else to a more wholly active one, than is usual among the orders of men, who commonly, in virtue of their priesthood, have been able to find a mixed form of life between the two extremes. The nuns belonging to the older orders tend to the contemplative idea, and they still find recruits in sufficient numbers, in spite of the modern rush to the active congregations. These latter exist in wondrous number and variety, exercising every imaginable form of good work—education, both primary and secondary; the care of hospitals, orphanages, penitentiaries, prisons; of asylums for the blind, the deaf and dumb, the insane; of refuges for the aged poor and the destitute.

See the works of Helyot and Heimbucher, referred to below under "Literature"; also Lina Eckenstein, *Woman under Monasticism* (1896); and for information on the various orders of women, J. N. Murphy, *Terra incognita* (1873); and F. M. Steele, *Convents of Great Britain and Ireland* (1902).

16. *Conclusion.*—Few phenomena are more striking than the change that has come over educated Protestant opinion in its estimate of monasticism. The older Protestantism uncompromisingly judged the monastic ideal and life to be both unchristian and unnatural, an absolute perversion deserving nothing but condemnation. But now the view of the critico-historical school of Protestant thought, of which Dr Adolf Harnack is so representative a spokesman, is that the preservation of spiritual religion in Catholic Christianity, both Eastern and Western, has been mainly, if not wholly, due to monasticism (see Harnack's early tractate *Das Mönchtum*, translated under the title *Monasticism*, by E. E. Kellett, 1901; also the lectures on Greek and Roman Catholicism in *Das Wesen des Christentums*, translated by Bailey Saunders, 1902; the first-named work is the most suggestive general *aperçu* of the whole subject—though written from a frankly hostile standpoint, it is in large measure a panegyric).

The views of the new Protestantism concerning monasticism are probably no less excessive than those of the old. The truth probably lies somewhere between them. It may perhaps be agreed that not the least of the services rendered to the Christian people at large by monasticism is this: Into every life the spirit of renunciation must enter; in most lives there are crises in which the path of mere duty can be followed only in virtue of a great renunciation; if we are able to make these ordinary and necessary renunciations, it is in some measure owing to the fact that the path has been made easier for us by those who (like the author of the *Imitation of Christ*) have shown the example, and thereby been able to formulate the theory, of renunciation in a supreme degree.

Literature.—The literature on monasticism is immense. The chief repertory for information on the historical side is Helyot's *Histoire des ordres religieux* (8 vols., 1714; 2nd ed. 1792; digested in dictionary form by Migne, 1860). This information has been condensed and brought up to date by Max Heimbucher, *Orden und Kongregationen* (2 vols., 1896–1897; a 2nd ed. in 3 vols., 1907)—this most useful handbook is equipped throughout with an excellent and well chosen bibliography. Otto Zöckler's *Askese und Mönchtum* (1897), also covers the whole ground, and is written more from the point of view of theory. The inner spirit and working of the older monasticism is well portrayed in F.A. Gasquet's *English Monastic Life* (1904); more popular accounts are given in H. J. Feasy's *Monasticism* (1898), and F. M. Steele's *Monasteries and Religious Houses of Great Britain and Ireland* (1903). The rules of the various orders are collected in Brockie's edition of Holsten's *Codex regularum* (6 vols., 1759). The article *Mönchtum* in Herzog-Hauck *Realencyklopädie* (3rd ed.), and in Wetzer und Welte *Kirchenlexicon* (2nd ed.) go over the same general ground as the present article, in the earlier portion entering into greater detail as to facts, but in the later dealing much more summarily. The relevant separate articles in these two great dictionaries, Protestant and Catholic respectively, will supply adequate information and ample references on most points. The *Catholic Dictionary* contains useful articles on most of the subjects here touched on; and an extensive *Catholic Encyclopaedia* is in course of preparation at the Catholic University of Washington. The habits and dress of the various orders may be seen in Helyot's *Histoire*, which abounds in plates, coloured, in the ed. of 1792. There are plates representing members of the chief orders in Dugdale's *Monasticon*, and in the books of Gasquet and Steele mentioned above; also (coloured) in Tuker and Malleson, *Handbook to Christian Rome*, pt. iii. (1900). (E. C. B.)

MONASTIR, or Bitolia, the second city of Macedonia, and the capital of the vilayet of Monastir in European Turkey, on the Salonica-Monastir railway, 400 m. W. of Constantinople. Pop. (1905), about 60,000. Monastir is situated at an altitude of 2019 ft. on the eastern versant of the richly wooded mountains which culminate in the Peristeri (8300 ft.) and sever Lake Prespa from the valley of the Kara-Su or Tzerna. A tributary of this river, the Dragor or Drahor, traverses Monastir through a rocky channel which is rarely filled except after a thaw or heavy rain. The city possesses many mosques, churches and schools, baths and a military hospital. It is the seat of numerous consulates, an American Protestant mission, and a Lazarist mission. The annual value of its trade is about £400,000. Grain, flour, cloth, hides and bones are exported, and a large amount of gold and silver ornaments is manufactured, though this industry tends to decline.

The military advantages of its position at the meeting-place of roads from Salonica, Durazzo, Uskub, and Adrianople led the Turks, about 1820, to make Monastir the headquarters of an army corps. Since then the general and commercial importance of the city has greatly increased, and in 1898 it was made the see of a Bulgarian bishop. The ancient diocese of its Greek archbishop is known as Pelagonia, from the old name of the Kara-Su Plain. Monastir itself has been identified with the ancient Heraclea Lyncestis on the Via Egnatia; its modern name is derived from the monastery of Bukova (" the beeches ") near the southern outskirts of the city.

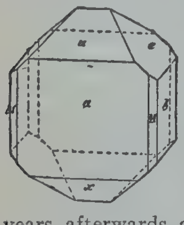
MONAZITE, a mineral consisting of anhydrous phosphate of the cerium metals (Ce, La, Di)PO_4, together with small and variable amounts of thorium (ThO_2, 1–10%) and yttrium. It is of considerable commercial importance as a source of thoria for the manufacture of the Welsbach and other mantles for incandescent gas-lighting: the cerium is used to a limited extent in pharmacy.

The following analyses are of monazite from: (I.) Burke county, North Carolina; (II.) Arendal, Norway; (III.) Emmaville, Gough county, New South Wales.

	I.	II.	III.
Phosphorus pentoxide (P_2O_5)	29·28	27·55	25·09
Cerium oxide (Ce_2O_3)	31·38	29·20	36·64
Lanthanum oxide (La_2O_3) Didymium oxide (Di_2O_3)	30·88	26·26	30·21
Yttrium oxide (Yt_2O_3)	—	3·82	—
Thorium oxide (ThO_2)	6·49	9·57	1·23
Silica (SiO_2)	1·40	1·86	3·21
Alumina (Al_2O_3)	—	—	3·11
Iron oxide (Fe_2O_3)	—	1·13	—
Lime (CaO)	—	0·69	—
Water (H_2O)	0·20	0·52	—
	99·63	100·60	99·49
Specific gravity	5·10	5·15	5·001

Thoria and silica being often present in the molecular ratio 1 : 1, it has been suggested that they exist as thorite ($ThSiO_4$) as a mechanical impurity in the monazite.

Crystals of monazite belong to the monoclinic system, and are usually flattened parallel to the ortho-pinacoid (*a* in the figure). The large (up to 5 in. in length) reddish-brown, dull and opaque crystals from Norway and the Urals are simple in form, whilst the small, translucent, honey-yellow crystals from the Alps are bounded by numerous bright faces. Crystals of the latter habit were described in 1823 from Dauphiné under the name turnerite, and owing to their rarity were not until many years afterwards analysed chemically and proved to be identical with monazite. Monazite from the Urals was described by A. Breithaupt in 1829, and named by him from Gr. *μονάζειν*, to be solitary, because of the rarity of the singly occurring crystals. The hardness is 5½, and the specific gravity 5·1–5·2. Light which has traversed a crystal or grain of monazite exhibits a characteristic absorption spectrum, and this affords a ready means of detecting the mineral.



As minute idiomorphic crystals monazite is of wide distribution in granites and gneisses, being present in very small amounts as an accessory constituent of these rocks. By powdering the rock and washing away the lighter minerals in a stream of water the heavy minerals (zircon, anatase, rutile, magnetite, garnet, monazite, xenotime, &c.) may be collected. This separation has been effected naturally by the weathering and disintegration of the rocks and the accumulation of the heavier minerals in the beds of streams. Under these conditions monazite has been found as rounded water-worn grains in the alluvial gold-washings of the Urals, Finland, Siberia, the United States, Brazil, Colombia, New South Wales, &c., and in tin-gravels in Swaziland, South Africa. Larger crystals of monazite are found embedded in pegmatite veins in the Ilmen Mountains (southern Urals); at Arendal and other places in southern Norway, where it is collected in the feldspar quarries to the extent of about one ton per annum; and in the mica mines at Villeneuve in Quebec, where masses of monazite weighing 20 ℔ have been found. The small crystals of the " turnerite " habit occur implanted, often with anatase and rutile, on the crystallized quartz and albite, which line crevices in the crystalline schists of the French, Swiss and Tirolese Alps; similar crystals with the same associations occur very exceptionally in the clay-slate at Tintagel in Cornwall. Microscopic crystals of monazite (cryptolite, from *κρυπτός*, concealed) have been observed embedded in the crystallized apatite of Arendal in Norway.

The deposits worked commercially are the monazite-bearing sands of North Carolina and Brazil, and to a smaller extent those of South Carolina. In North Carolina it occurs over a wide area in the streams rising in the South Mountains, an eastern outlier of the Blue Ridge. The rocks of the district are granitic biotite-gneiss and hornblende-gneiss, and are intersected by veins of auriferous quartz. The percentage of monazite in the river-gravels varies from very small amounts up to 1 or 2%. The heavy minerals contained in the gravels are collected in the same manner as in washing for gold (which is often also present); magnetite is separated with a magnet; but other minerals, such as zircon, rutile, garnet, corundum, &c., cannot be separated by mechanical means. The product is a fine-grained yellowish sand containing 65–85% of monazite and 3–9% of thoria. In Brazil it occurs in river-gravels and also in the sand on the sea-beaches; an extensive accumulation of very rich monazite sand occurs on the seashore near Alcobaça in Bahia, and this has been shipped as ballast in the natural state.

See H. B. C. Nitze, " Monazite " (*16th Annual Report of the United States Geological Survey*, pt. iv. (1895), pp. 667–693). (L. J. S.)

MONBODDO, JAMES BURNETT, Lord (1714–1799), Scottish judge and anthropologist, was born in 1714 at Monboddo in Kincardineshire. He studied at Aberdeen, and, after passing his law examinations in Edinburgh, he quickly took a leading position at the Scottish bar, being made a Lord of Session in 1767 with the title of Lord Monboddo. Many of his eccentricities, both of conduct and opinion, appear less remarkable to us than they did to his contemporaries; moreover, he seems to have heightened the impression of them by his humorous sallies in their defence. He may have had other reasons than the practice of the ancients for dining late and performing his journeys on horseback instead of in a carriage. He is remembered more particularly for his writings on human origins. In his *Antient Metaphysics* (1779–1799), Monboddo conceived man as gradually elevating himself from an animal condition, in which his mind is immersed in matter, to a state in which mind acts independently of body. In his equally voluminous work, *The Origin and Progress of Language* (1773), he brought man under the same species as the orang-outang. He traced the gradual elevation of man to the social state, which he conceived as a natural process determined by " the necessities of human life." He looked on language (which is not " natural " to man in the sense of being necessary to his self-preservation) as a consequence of his social state. His views about the origin of society and language and the faculties by which man is distinguished from the brutes have many curious points of contact with Darwinism and neo-Kantianism. His idea of studying man as one of the animals, and of collecting facts about savage tribes to throw light on the problems of civilization, bring him into contact with the one, and his intimate knowledge of Greek philosophy with the other. In both respects Monboddo was far in advance of his neighbours. His studied abstinence from fine writing—from " the rhetorical and poetical style fashionable among writers of the present day "—on such subjects as he handled confirmed the idea of his contemporaries that he was only an eccentric concocter of supremely absurd paradoxes. He died on the 26th of May 1799.

Boswell's *Life of Johnson* gives an account of the lexicographer's visit to Burnett at Monboddo, and is full of references to the natural contemporary view of a man who thought that the human race could be descended from monkeys.

MONCEY, BON ADRIEN JEANNOT DE, Duke of Conegliano (1754–1842), marshal of France, was the son of a lawyer of Besançon, where he was born on the 31st of July 1754. In his boyhood he twice enlisted in the French army, but his father procured his discharge on both occasions. His desire was at last gratified in 1778, when he received a commission. He was a captain when, in 1791, he embraced the principles of the French Revolution. Moncey won great distinction in the campaigns of 1793 and 1794 on the Spanish frontier (see French Revolutionary Wars), rising from the command of a battalion to the command in chief of the Army of the Western Pyrénées in a few months, and his successful operations were largely instrumental in compelling the Spanish government to make peace. After this he was employed in the highest commands until 1799, when the government, suspecting him of Royalist views, dismissed him. But the *coup d'état of* 18. Brumaire brought him back to the active list, and in Napoleon's Italian campaign of 1800 he led a corps from Switzerland into Italy, surmounting all the difficulties of bringing horses and guns over the then formidable pass of St Gothard. In 1801 Napoleon made him inspector-general of gendarmerie, and on the assumption of the imperial title created him a marshal of France. In 1805 Moncey received the grand cordon of the legion of honour, and in 1808 the title of duke of Conegliano. In the latter year, the first of the Peninsular War, Moncey was sent to Spain in command of an army corps. He signalized himself by his victorious advance on Valencia, the effect of which was, however, destroyed by the disaster to Dupont at Baylen, and took a leading part in the emperor's campaign on the Ebro and in the second siege of Saragossa in 1809. He refused to serve in the invasion of Russia, and therefore had no share in the campaign of the *grande armée* in 1812 and 1813. When, however, France was invaded (1814) Marshal Moncey reappeared in the field and fought the last battle for Paris on the heights of Montmartre and at the barrier of Clichy. He remained neutral during the Hundred Days, feeling himself bound to Louis XVIII. by his engagements as a peer of France, but after Waterloo he was punished for refusing to take part in the court-martial on Ney by imprisonment and the loss of his marshalate. He was reinstated in 1816, and re-entered the chamber of peers three years later. His last active service was as commander of an army corps in the short war with Spain, 1823. In 1833 he became governor of the Invalides. He died on the 20th of April 1842.

MONCHIQUE, a town of southern Portugal, in the district of Faro (formerly the province of Algarve); 13 m. S. of Saboia station on the Lisbon-Faro railway, and 12 m. N. of Villa Nova on the Atlantic. Pop. (1900), 7345. Monchique is one of the principal Portuguese health-resorts, finely situated among the wooded heights of the Serra de Monchique, which rise on the west to 2963 ft. There are hot sulphur springs, with baths and a sanatorium 4 m. south. Wheat, millet, rye, beans, oranges, wine, olive oil and chestnuts are the chief products, and there is a woollen factory.

MONCTON, a city and port of entry in Westmoreland county, New Brunswick, Canada, 89 m. by rail N.E. of St John, at the head of navigation on the Petitcodiac river, the seat of the workshops and general offices of the Inter-Colonial railway and the eastern terminus of the new Grand Trunk Pacific railway. Pop. (1901), 9026. It has large stove factories, engine and boiler works, and is a flourishing manufacturing town. The workshops of the railway and great part of the town were swept away by fire in February 1906, but have been rebuilt on a larger and more modern scale.

MOND, LUDWIG (1839–1909), British chemist, was born at Cassel in Germany on the 7th of March 1839. After studying at Marburg under Hermann Kolbe and at Heidelberg under Robert Bunsen, he came to England in 1862 and obtained a position in a chemical works at Widnes, where he elaborated the practical application of a method he had devised for recovering the sulphur lost as calcium sulphide in the black ash waste of the Leblanc alkali process. He became a naturalized British subject in 1867. In 1873 he entered into partnership with Sir John Tomlinson Brunner (b. 1842–   ), whom he had met when he was at Widnes, and thus founded the great chemical manufacturing firm of Brunner, Mond & Co. They began to make alkali by the ammonia-soda process, under licence from the Belgian chemist, Ernest Solvay, but at first the venture threatened to prove a failure. Gradually, however, the technical difficulties were overcome and success assured, largely as a result of improved methods worked out by Mond for the recovery of the ammonia. About 1879 he began experiments in the economical utilization of fuel, and his efforts led him to the system of making producer-gas, known by his name (see Gas: II. *For Fuel and Power*). Later, while attempting to utilize the gas for the production of electricity by means of a Grove gas battery, he noticed that the carbon monoxide contained in it combined with nickel. The resulting compound, nickel carbonyl, which was described to the Chemical Society in 1890, is both formed and decomposed within a very moderate range of temperature, and on this fact he based a successful process for the extraction of nickel from its ores. A liberal contributor to the purposes of scientific research, Mond founded in 1896 the Davy-Faraday Research Laboratory in connexion with the Royal Institution. On his death, which occurred in London on the 11th of December 1909, he bequeathed a large part of his collection of pictures to the nation.

MONDAY (in O.E. *Monandaeg*, the moon's day, a translation of the Late Lat. *Lunae dies*, from which the French *lundi* is taken), the second day of the week (see Calendar). The day has been humorously canonized as St Monday, the festival of cobblers, who seldom work on Mondays, and were supposed not to know exactly on which day St Crispin's (their patron saint) festival fell, save that it should be a Monday, and thus celebrated each Monday in the year as a holiday so as to be certain to honour the day. In some parts of Yorkshire any holiday is called Cobblers' Monday. Collop Monday, in the north of England, is the Monday before Shrove Tuesday, so called in allusion to the dish of fried eggs and bacon, and slices of salted, dried meat, called collops, taken on that day preparatory to the Lenten fast. Plough Monday in England is the Monday after Twelfth Day, the first Monday after Epiphany, in allusion to the fact that in medieval times the ploughmen had their fête-day and went around the villages begging plough-money. The lord mayor of London holds a Grand Court of Wardmote at the Guildhall on Plough Monday of each year, to receive returns from the wards of the election of common councilmen and to hear petitions against such returns.

MONDOÑEDO, a city of northern Spain, in the province of Lugo, 27 m. N.N.E. of the city of Lugo, on the river Masma. Pop. (1900), 10,590. Mondoñedo occupies a sheltered valley among the northern outliers of the Cantabrian Mountains. The principal buildings are the cathedral, a Corinthian structure of the 17th century, an ex-convent of Franciscan friars of Alcantara, which is used for a theatre and a public school, and the civil hospital. The industries include lace-making, linen-weaving, and leather manufacture.

According to local tradition, the bishopric of Dumium, near Braga, was transferred to San Martin de Mondoñedo (10 m. from Mondoñedo) in the 8th century; it was brought to Mondoñedo itself in the beginning of the 12th century. After having been for nearly a century and a half in the hands of the Moors, Mondoñedo was recaptured by Ordoño I. in 858; and the Christian possession was made permanent by Alphonso III. in 870. It was taken by surprise by the French in 1809.

MONDOVÌ, a town and episcopal see of the province of Cuneo, Piedmont, Italy, 17 m. by rail E. of Cuneo. Pop. (1901), 5379 (town); 18,982 (commune). The lower town is 1283 ft.

above sea-level, the upper 1834 ft. There is a school of the industrial arts and handicrafts, and majolica, paper, and silk cocoons are produced. The upper town contains the hexagonal piazza, a citadel, erected in 1573 by Emanuel Philibert, the cathedral of S. Donatus, a spacious episcopal palace, and higher up is a tower, the Belvedere, with a fine view. At the foot of the hill along the banks of the Ellero (a tributary of the Po) lie the industrial and commercial suburbs of Breo, Borgatto, Pian della Valle and Carassone, with their potteries, tanneries, paper-mills, marble-works, &c. The mansion of Count San Quintino in Pian della Valle was the seat of the printing-press which from 1472 issued books with the imprint Mons Regalis.

Mondovì—Mons Vici, Mons Regalis, Monteregale—did not take its rise till about A.D. 1000. The bishopric dates from 1388. About 2 m. to the east is the sanctuary of Vico, a church designed by Ascanio Vittozzi in 1596 and crowned by a famous dome (1730–1748), which has been declared a national monument. In the square before it is a monument (1891) to Charles Emmanuel I. of Savoy.

See L. Melano Rossi, *The Sanctuario of the Madonna di Vico* (London, 1907).

MONET, CLAUDE (1840–), French painter, was born in Paris on the 14th of November 1840. His youth was passed at Hâvre, where his father had settled in 1845. Until he was fifteen years old he led a somewhat irregular life, learning little at school, and spending all his time in decorating his books with drawings and caricatures which gave him notoriety in Hâvre. At the same time he became acquainted with Boudin, a clever sea-painter, under whose guidance he learned to love and to understand nature. At the age of twenty he became a soldier, and spent two years of his military time with the regiment of the Chasseurs d'Afrique in the desert. Falling ill with fever, he was sent home, and entered the studio of Gleyre. This classical painter tried in vain to keep him to conventional art and away from truth and nature, and Monet left his studio, where he had become acquainted with two other "impressionistic" painters—Sisley and Renoir. At that time he also knew Manet (*q.v.*), and in 1869 he joined the group of Cézanne, Degas, Duranty, Sisley, and became a *plein air* painter. During the war of 1870 he withdrew to England, and on his return was introduced by Daubigny to a dealer, M. Durand-Ruel, in whose galleries almost all his works have been exhibited. In 1872 he exhibited views of Argenteuil, near Paris; in 1874 a series entitled "Cathedrals," showing the cathedral of Rouen under different lights. He afterwards painted views of Vétheuil (1875, see Plate), Pourville and cliffs of Etretat (1881), of Bordighera (1886), of the Creuse (1889), Le Meules (1891), and some further views of cathedrals (1894). In December 1900 he exhibited some pictures called "Le Bassin des Nymphéas," and was engaged at the beginning of 1901 in painting views of London. Several of Monet's paintings, bequeathed by M. Caillebotte, are in the Luxembourg Museum, Paris. (See IMPRESSIONISM.)

MONETARY CONFERENCES (INTERNATIONAL). These assemblies were one of the features of the latter half of the 19th century, due to the decided tendency towards securing reforms by concerted international action. The disorganized state of the European currencies, which became more serious in consequence of the great expansion in trade and industry, came into notice through the great gold discoveries and their effect on the relations between the two precious metals. Both by its situation and its currency system, France was the country that was first led to aim at the establishment of a currency union, in which French ideas and influences would be predominant. A preliminary step was the formation of the Latin union, whereby the currencies of France, Italy, Belgium and Switzerland were—in respect to their gold and silver coins—assimilated. In 1867 the Paris Exhibition furnished the occasion for summoning a monetary conference, to which the principal countries of the world sent representatives. The guiding spirit of this assembly was the eminent economist, De Parieu, who had originated the Latin Union. By his advice a scheme was approved recommending the adoption of the single gold standard, the use of the decimal system, and the co-ordination of the various currencies with the French system. Difficulties as to the mode of bringing these principles into practical operation were discussed, and full liberty had to be given to the several nations to carry out the proposals in the way that seemed best. The result proved that the obstacles were insurmountable, *e.g.* the British government could not obtain the assent of a Royal Commission to the assimilation of the sovereign to the 25-franc piece; and the course of political events soon completely altered the relative position of the leading countries, even in their monetary relations. Germany and the United States reformed their currencies, without reference to any international considerations.

The meeting of the next international conference took place under very different conditions. A great fall in the value of silver as measured in gold, in progress from 1873, had affected the relations of silver-using countries, and disturbed the level of prices. Indian interests as well as those of American producers of silver suffered, while the management of all double-standard currencies became a task of increasing difficulty. The government of the United States invited the representatives of the leading powers to meet in Paris for the purpose of considering (1) the desirability of retaining the unrestricted use of silver for coinage, (2) the adoption of international bimetallism (*q.v.*), by the acceptance of a ratio to be fixed by agreement. Eleven nations sent delegates, Germany being the only great power unrepresented. After somewhat protracted discussion and the presentation of a large number of documents the European states accepted the American proposition "that it is necessary to maintain in the world the monetary functions of silver"; but declined to bind the discretion of particular states as to the methods to be employed. They further declared it impossible to enter into an agreement for a common ratio. The conference, therefore, separated without any result being obtained.

In consequence of the continuing fall in the value of silver, which stimulated the bimetallic agitation, a third conference was convened by the joint action of France and the United States; it also met in Paris, and was more influential than its predecessor, since Germany sent representatives, as did Spain, Portugal, Denmark and India. The characteristic of this conference was the greater strength of the support given to the bimetallic proposal by France and the United States, together with the opposition of the delegates of the smaller European countries, and the refusal of Germany to promise any co-operation. The inevitable consequence of this situation was the adjournment of the conference to obtain fresh instructions, which, however, were never furnished.

After several abortive attempts the fourth (and last) of the conferences of this class was brought together at Brussels in November 1892 on the initiative of the United States. A full representation of the powers attended, but delay arose from the absence of definite proposals by the American government. These, when they were presented, proved to be only a reaffirmation of the bimetallic policy, and showed no advance. The conference, therefore, proceeded to consider the plans of Levy, Baron de Rothschild and Sotbeer for the more extended use of silver. Such devices, being merely alleviations, failed to gain any effective support. Appeals to England and Germany to grant some concessions likewise failed. Thus, like its Paris forerunners, the Brussels conference adjourned, but never resumed its sittings.

After 1892 the currency problem passed into a new stage, in which action was national rather than international. The method of procedure by conference was for the time abandoned.

The proceedings of the several conferences have been issued by the governments taking part in them. Those of the United States are the most convenient for English and American readers. See also H. B. Russell, *International Monetary Conferences* (New York, 1898). (C. F. B.)

MONEY. 1. *Definition and Functions.*—The difficult question as to the best definition of money has been complicated by the efforts of writers so to define the term as to give support to their particular theories. It is hard to frame a precise account which will hold good of the many objects that have served for monetary use. From denoting coined metal, money has come to include anything that performs the money work: though there has been considerable hesitation in extending the term to those forms of credit that are in modern societies the chief instrument of exchange. It is therefore best to avoid a formal definition; and, instead, to bring out the character of money by describing the functions that it performs in the social system. The most important is, clearly, that of facilitating exchange. It is not necessary to dwell on the great importance of this office. The slightest consideration of industrial organization shows that it is based on the division of employments; but the earliest economic writers saw plainly that division of employments was only possible through the agency of a medium of exchange. They recognized that the result of increasing specialization of labour was to establish a state of things in which each individual produced little or nothing for the direct satisfaction of his own wants, and had therefore to live by exchanging his product for the products of others. They saw, further, that this only became feasible by the existence of an article that all would be willing to accept for their special products; as otherwise the difficulty of bringing together persons with reciprocal wants would prove an insurmountable obstacle to that development of exchange, which alone made division of labour possible. A *second* function hardly inferior in importance to the one just mentioned is that of affording a ready means for estimating the comparative values of different commodities. Without some common object as a standard of comparison this would be practically impossible. "If a tailor had only coats and wanted to buy bread or a horse, it would be very troublesome to ascertain how much bread he ought to obtain for a coat or how many coats he should give for a horse"; and as the number of commodities concerned increased the problem would become harder, "for each commodity would have to be quoted in terms of every other commodity." There is, indeed, a good deal to be said for the view that the conception of general exchange value could never have been formed without the previous existence of money; it has certainly support from the evidence of competent observers respecting the methods of exchange followed by savage communities. The selection of some particular article as the criterion makes the comparison of values easy. "The chosen commodity becomes a *common denominator*, or *common measure of value* in terms of which we estimate the value of all other goods," and in this way money, which in its primary function renders exchange possible by acting as an intermediate term in each transfer, also makes exchanges easier by making them definite. Still another function of money comes into being with the progress of society. One of the most distinctive features of advancing civilization is the increasing tendency of people to trust each other. There is thus a continuous increase in relations arising from contract, as can be seen by examining the development of any legal system. Now, a contract implies something to be done in the future, and for estimating the value of that future act a standard is required; and here money which has already acted as a *medium of exchange* and as a *measure of value* at a given time, performs a *third* function, by affording an approximate means of estimating the present value of the future act; in this respect it may be regarded as a *standard of value*, or as some prefer to say, of *deferred payments.* Nor does this exhaust the list of services that money renders. In the earlier stages of economic life it acts as a *store of value*; for in no other way could a large body of wealth be concentrated. Though this is no longer needed by individuals, even at the present day the great banks find that their reserves must take the form of a monetary store. Again, money in its various forms has been the great agency for transmitting values from place to place. Its international function in this respect still continues. The balance of debt between countries is ultimately settled by the passage of bullion from the debtor to the creditor nation. But, though money has these powers, it is nevertheless correct to say that its essential functions are three in number, *i.e.* it supplies: (1) the common medium by which exchanges are made possible; (2) the common measure by which the comparative values of those exchanges are estimated; (3) the standard by which future obligations are determined.

2. *The Value of Money, its Determining Causes. The Quantity of Money required by a Country.*—The value of money is in principle only a special case of the general problem of value; but owing to its peculiar position the medium of exchange has in this respect become surrounded by difficulties that need to be removed. The very phrase "value of money" is employed in two senses, which on the surface seem to have no connexion with each other, and are the cause of much confusion to those who have not looked into the matter. In mercantile phraseology the value of money means the interest charged for the use of loanable capital. When the market rate of interest is high, money is said to be dear; when it is low, money is regarded as cheap. Without entering into the reasons for this use of the term, it is sufficient to state the other and for our present purpose more correct meaning of the phrase. As the value of a thing is what it will exchange for; so "the value of money is what money will exchange for, or its purchasing power. If prices are low, money will buy much of other things, and is of high value; if prices are high, it will buy little of other things, and is of low value. The value of money is inversely as general prices, falling as they rise and rising as they fall." Now the *proximate* condition under which value is determined is admittedly the establishment of an equation between demand and supply. In the case of money, however, some explanation as to the nature of both these elements in the problem becomes necessary. In what forms is the supply of, and the demand for, money exhibited? The supply of a commodity is the quantity of it which is offered for sale. But in what shape does the sale of money take place? Plainly, by being offered for goods. The supply of money is the quantity of it which people are wanting to lay out, *i.e.* all the money in circulation at the time. Demand, in like manner, means the quantity of a commodity desired, or, according to another mode of expression, the amount of purchasing power offered for it. Taking the latter as the more convenient for the case of money, we can say that the demand for it consists in all goods offered for sale. The position of money as the medium of exchange introduces a further novel feature; for the market in its case is world-wide and the demand is unceasing; money is consequently in a constant state of supply and demand. It thus appears that the factors determining the value of money at a given time are: (1) the amount of money in circulation, and (2) the amount of goods on sale. Closer examination reveals other influencing conditions. The mere quantity of money is not the only element on the supply side. The varying circulation of the monetary units must be taken into account. Some coins do not make a single purchase in a year, while others change hands in transactions hundreds of times. By averaging, we may estimate the effect of the rapidity with which money does its work, or, to employ a technical term, the "efficiency of money." Similarly, the amount of sales rather than the quantity of commodities is the determining element on the demand side. Thus, if the influence of credit be omitted, it is true to say that the value of money varies inversely as its quantity multiplied by its efficiency, the amount of transactions being assumed to be constant. Some additional explanation is required before this formula can be accepted as an expression of the whole truth on the subject. It must be noticed that it is not commodities only that are exchanged for money. Services of all kinds constitute a large portion of the demand for the circulating medium, while the payment of interest on the many kinds of obligations makes a further call on it. The potent influence of credit must also be recognized. The latter force is indeed the chief agency to be considered in dealing with the variations of prices; though so far as it is based on deposits of metallic money it may be regarded as a form of increased monetary efficiency, and therefore as coming within the formula given above. In its wider aspect, credit acts as a substitute for ordinary money, and may be interpreted as equivalent to a system of perfected barter, or, better, as a new currency development. An interesting but paradoxical conclusion should be noticed: it is that increased

trade and expanding business are causes which operate not to raise, but to lower prices; for by enlarging the work that money has to do they raise its value, *i.e* provided that other things remain the same. Another more obvious deduction is that a large addition to the stock of money does not necessarily raise prices, since money is only effective when brought into circulation.

The chief topic of dispute in respect to the theory of money-value has been concerned with the question as to the ultimate regulating influence. The value of freely produced commodities is—according to economic theory—determined by "cost of production," or, where the article is produced at different costs, by the cost of production under the most unfavourable circumstances. As demand varies with price, it follows that an adjustment of value takes place through the interaction of cost and demand, the latter indicating the influence of the utility of the commodity on the quantity required. In applying the theory to the special case of money, the first consideration is the fact that gold and silver, the principal money materials, are the products of mines, and are produced at different costs, so that their values depend on the portions raised at greatest cost. We thus obtain the proposition that has figured in so many text-books; viz. that "the value of money depends on its cost of production." The theory of normal value, however, involves certain assumptions, which are significant in this connexion. Competition is conceived as absolutely free; it is assumed that there are accurate *data* for computing costs, and that the determination of value by cost is effective only "in the long run." It is recognized, also, that cost operates on value through its power in regulating supply. "The latent influence," says Mill, "by which the value of things are made to conform in the long run to the cost of production is the variation that would otherwise take place in the supply of the commodity." From such considerations it follows that the influence of cost on the value of money is not so predominant as a rigid interpretation of the theory of value seems to suggest.

In earlier times it has been a common proceeding on the part of governments to restrict or stimulate both mining for the precious metals and the business of coining. At all times the working of gold and silver mines has been rather a hazardous speculation than a legitimate business. "When any person undertakes to work a new mine in Peru," says Adam Smith, "he is universally looked upon as a man destined to bankruptcy and ruin, and is upon that account shunned and avoided by everybody. Mining, it seems, is considered there in the same light as here, as a lottery in which the prizes do not compensate the blanks." The modern capitalistic organization of gold mining has not done much to alter this condition. As regards the adjustment of supply to meet an altered cost of production the difficulties are, if possible, greater. The actual supply of money is so large, when compared with the annual production of the precious metals, that a change in output can operate but slowly on its value. The total stoppage of fresh supplies from the mines would not be sensibly felt for some years; and though increased production is more rapid in its operation, it takes some time to produce a decided effect. Hence the conclusion is reached that "the effects of all changes in the conditions of production of the precious metals are at first, and continue to be for many years, questions of quantity only, with little reference to cost of production." This is the position which is usually known as that of the "quantity" theory; though very different degrees of doctrine are comprised under the general title. With due qualification and comment it may be taken as the prevalent theory. At all events it is beyond dispute that the cost of production is not for short periods the controlling force which governs the value of money; while even for long periods its influence is very hard to ascertain, in consequence of the speculative nature of the industries of gold and silver mining. Another peculiar feature of the problem of money value arises from the fact that it is only through an actual change in the supply of money that its value can be altered. With other commodities the knowledge that they can be produced at lower cost will bring about a reduction in their value. In the case of money, this does not hold. There must be an adjustment of the amount, or of the efficiency, of the money stock, since, as explained above, it is in a constant state of supply and demand. Its value is established in the very process of carrying on exchanges, and that process is influenced by the available supply. In regard to another form of money the effect of the amount in existence is still more decisive. This is paper money, not immediately redeemable in coin. In this case the idea of cost is manifestly inapplicable; the quantity in circulation is evidently, as proved by abundant experience, the ruling influence on value. In fact, the "quantity" theory receives its simplest illustration in the case of inconvertible paper. The truth that the theory is but an instance of the action of supply and demand is equally shown by this prominent class of instances. Where metallic coinage is artifically limited the same principle holds good. The value of such currencies plainly depends on the conditions of supply and demand.

The immense growth of credit and its embodiment in instruments that can be used as substitutes for money has led to the promulgation of a view respecting the value of money which may be called the "credit" theory. According to the upholders of this doctrine, the actual amount of metallic money has but a trifling effect on the range of prices, and therefore on the value of money. What is really important is the volume of credit instruments in circulation. It is on their amount that price movements depend. Gold has become only the small change of the wholesale markets, and its quantity is comparatively unimportant as a determinant of prices. The theory has some connexion with the view of "money" as consisting in the loanable capital of the market, taking shape in the cheques that transfer liabilities. Thus the rate of interest comes to form a factor in the creation of "money," and the mercantile use of the phrase "value of money" receives a justification. Like the pure "cost" theory of money value, the "credit" theory gives too one-sided a view of the facts. In particular, it fails to recognize the ultimate dependence of all kinds of credit on the stock of money in the full sense, *i.e.* on metallic legal-tender money. The truths adumbrated in the theory are better expressed in the statement of the quantity theory in its developed form, as set forth above. It is necessary to take into account the varying quantities of the precious metals, the modes of use in respect to them; the influence of cost of production, and the way in which credit expedients replace standard money. A complete theory must include all these elements, while not unduly emphasizing any one of them.

At the beginning of statistical inquiry much attention was given to the question: What quantity of money does a country require for the proper working of its industrial system? Petty and Locke were ready to give definite answers; but modern inquirers decline making any quantitative statement, and content themselves with indicating the conditions to be considered. Amongst these are: Population, amount of transactions, the efficiency of money, the development of credit, and the height to which banking organization has attained. Other elements in the problem are the disposition towards hoarding, and the employment of some form of barter in transactions. The contrast between India and the United States in monetary and industrial habits supplies an effective series of illustrations on this matter. The conclusion is obvious that economic progress is accompanied by a more sparing use of money. The most important aspect of the question in modern times is in relation to the division of money between countries. Regarded from this point of view, the quantity of money that a country needs is that which will keep its prices in due level with those of the countries with which it has commercial relations. For, this is the condition of equilibrium; there would otherwise be an excess of either exports or imports, involving a transfer of money to adjust the balance. It may be added that the organization works automatically, since fluctuations in the stock of money are corrected by the action of trade. The best estimates place the gold circulation of the United Kingdom at somewhat under £100,000,000, the token currency at about £15,000,000, and the note circulation as nearly £43,000,000. The French use of metallic money is much larger; probably over £200,000,000, and the note circulation is also over £200,000,000.

3. *Early Forms of Currency.*—Up to the present we have considered money as being fully established and properly adapted to fulfil its various functions. We have now to trace the steps by which a suitable system of currency was evolved from a state of barter. It is important for a right understanding of the question to grasp the fact that exchanges took place originally between groups, and not between individuals. The slow growth of exchanges is thus explained, as each group produced most of the articles necessary for itself, and such acts of barter as took

place were rather reciprocal presents than mercantile exchanges. Such is actually the case among modern savages. "It is instructive to see trade in its lowest form among such tribes as the Australians. The tough greenstone valuable for making hatchets is carried hundreds of miles by natives, who receive from other tribes in return the prized products of their districts, such as red ochre to paint their bodies with; they have even got so far as to let peaceful traders pass unharmed through tribes at war, so that trains of youths might be met, each lad with a slab of sandstone on his head to be carried to his distant home and shaped into a seed-crusher. When strangers visit a tribe they are received at a friendly gathering or corrobboree, and presents are given on both sides. No doubt there is a general sense that the gifts are to be fair exchanges, and if either side is not satisfied there will be grumbling and quarrelling; but in this roughest kind of barter we do not yet find that clear notion of a unit of value which is the great step in trading." This vivid description of E. B. Tylor's enables us to realize the way in which money came into existence. When any commodity becomes an object of desire, not merely from its use to the persons desiring it, but from their wanting it as being readily exchangeable for other things, then that article may be regarded as rudimentary money. Thus the greenstone and ochre are on their way to being promoted to the position of currency, and the idea of a "unit of value" is all that is needed to complete the invention. "This higher stage is found among the Indians of British Columbia, whose strings of haiqua-shells worn as ornamental borders to their dresses serve them also as currency to trade with—a string of ordinary quality being reckoned as worth one beaver's skin." Such shells are in reality money, inasmuch as they discharge its functions.

On a review of existing savage tribes and ancient races of more or less civilization we are surprised at the great variety of objects which have been used to supply the need of a circulating medium. Skins, for instance, seem to be one of the earliest forms of money. They have been found among the Indians of Alaska performing this service, while accounts of leather money seem to show that their use was formerly more general. As the hunting stage gives place to the pastoral, and animals become domesticated, the animal itself, instead of its skin, becomes the principal form of currency. There is a great mass of evidence to show that, in the most distant regions and at very different times, cattle formed a currency for pastoral and early agricultural nations. Alike among existing barbarous tribes, and in the survivals discovered among classical nations, sheep and oxen both appear as units of value. Thus we find that at Rome, and through the Italian tribes generally, "oxen and sheep formed the oldest medium of exchange, ten sheep being reckoned equivalent to one ox. The recognition of these objects as universal legal representatives of value, or, in other words, as money, may be traced back to the epoch of a purely pastoral economy." The Icelandic law bears witness to a similar state of things; while the various fines in the different Teutonic codes are estimated in cattle. The Latin word *pecunia* (*pecus*) is an evidence of the earliest Roman money being composed of cattle. The English *fee* and the famous term *feudal*, according to its most probable etymology, are derived from the same root. In a well-known passage of the *Iliad* (vi. 235-6) the value of two different sets of armour is estimated in terms of oxen. The Irish law tracts bear evidence as to the use of cattle as one of the measures of value in early Irish civilization. Similarly, oxen from the principal wealth and the circulating medium among the Zulus and Kaffirs. On the testimony of an eye-witness we are assured that, "as cattle constitute the sole wealth of the people, so they are their only medium of such transactions as involve exchange, payment or reward." So also we find that cattle-rents are paid by the pastoral Indian tribes to the United States government. From the prominence of slavery in early societies it is reasonable to suppose that slaves would be adopted as a medium of exchange, and one of the measures of value in the Irish law tracts, *cumhal*, is said to have originally meant a female slave. They are at present applied to this purpose in Central Africa, and also in New Guinea. On passing to the agricultural stage a greater number of objects are found capable of being applied to currency purposes. Among these are corn—used even at present in Norway—maize, olive oil, coco-nuts and tea. The most remarkable instance of an agricultural product being used as currency is to be found in the case of tobacco, which was adopted as legal tender by the English colonists in North America. Another class of articles used for money consists of ornaments, which among all uncivilized tribes serve this purpose. The haiqua-shells mentioned before are an instance, cowries in India, whales' teeth among the Fijians, red feathers among some South Sea Island tribes, and finally, any attractive kinds of stone which can be easily worked. Mineral products, so far as they do not come under the preceding head, furnish another class. Thus salt was used in Abyssinia and Mexico; while the metals—a phenomenon which will require a more careful examination—have succeeded in finally driving all their inferior competitors out of the field, and have become the sole substances for money.

4. *The Metals as Money. Reasons for their Adoption. Superiority of Silver and Gold.*—The employment of metals as money material can be traced far back in the history of civilization; but as it is impossible to determine the exact order of their appearance in this capacity, it will be convenient to take them in the order of their value, beginning with the lowest. Iron—to judge from the statement of Aristotle—was widely used as currency. One remarkable instance is the Spartan money, which was clearly a survival of a form that had died out among the other Greek states; though it has often been attributed to ascetic policy. In conjunction with copper, iron formed one of the constituents of early Chinese currency, and at a later time was used as a subsidiary coinage in Japan. Iron spikes are used as money in Central Africa, while Adam Smith notes the employment of nails for the same purpose in Scotland. Lead has served as money, *e.g.* in Burma. The use of copper as money has been more extensive than is the case in respect to the metals just mentioned. It, as stated, was used in China along with iron—an early instance of bimetallism—and it figured in the first Hebrew coins. It was the sole Roman coinage down to 269 B.C. and it has lingered on to a comparatively recent date in the backward European currencies. It even survives as a part of the token coinage of the present. Tin has not been a favourite material for money: the richness of the Cornish mines accounts for its use by some British kings. Silver holds a more prominent place than any of the preceding metals. Down to the close of the 18th century it was the chief form of money, and often looked on as forming the necessary standard substance. It was the principal Greek money material, and was introduced at Rome in 269 B.C. The currencies of medieval Europe had silver as their leading constituent; while down almost to the present day Eastern countries seemed to prefer silver to gold.

The pre-eminence of gold as money is now beyond dispute; there, is, however, some difficulty in discovering its earliest employment. It is, perhaps, to be found in "the pictures of the ancient Egyptians weighing in scales heaps of rings of gold and silver." According to W. Ridgeway's ingenious theory gold comes into use as a currency in due equation to the older cattle-unit, the ox. It was certainly employed by the great Eastern monarchs; its further development will be considered later on. Metals of modern discovery—such as nickel and platinum—are only used by the fancy of a few governments, though the former makes a good token coinage.

The preceding examination of the varied materials of currency, metallic and non-metallic, suggests some conclusions respecting the course of monetary evolution, viz.: (1) that the metals tend to supersede all other forms of money among progressive communities; and (2) that the more valuable metals displace the less valuable ones. The explanation of these movements is found in the qualities that are specially desirable in the articles used for money. There has been a long process of selection and elimination in the course of monetary history.

First, it is plain that nothing can serve as money which has not the attributes of wealth; *i.e.* unless it is useful, transferable and limited in supply. As these conditions are essential to the existence of value, the instrument for measuring and transferring values must possess them. A second requisite of great effect is the amount of value in proportion to weight or mass. High value in small bulk gives the quality of portability, want of which has been a fatal obstacle to the continued use of many early forms of money. Skins, corn and tobacco were defective in this quality, and so were iron and copper. Sheep and oxen, though technically described as "self-moving," are expensive to transport from place to place. That the material of money shall be the same throughout, so that one unit shall be equal in value to another, is a further desideratum, which is as decidedly lacking in cattle-currency as it is prominent in the metals. It is, further, desirable that the substance used as money shall be capable of being divided without loss of value, and, if needed, of being reunited. Most of the articles used in primitive societies—such as eggs, skins and cattle—fail in this quality. Money should also be durable, a requirement which leads to the exclusion of all animal and most vegetable substances from the class of suitable currency materials. To be easily recognized is another very desirable quality in money, and moreover to be recognized as of a given value. Articles otherwise well fitted for money-use, *e.g.* precious stones, suffer through the difficulty of estimating their value. Finally, it results from the function of money as a standard of value that it should alter in its own value as little as possible. Complete fixity of value is from the nature of things unattainable; but the nearest approximation that can be secured is desirable. In early societies this quality is not of great importance; for future obligations are few and inconsiderable. With the growth of industry and commerce and the expansion of the system of contracts, covering a distant future, the evil effects of a shifting standard of value attract attention, and lead to the suggestion of ingenious devices to correct fluctuations. These belong to the later history of money and currency movements. It is enough for the ordinary purposes of money that it shall not alter within short periods, which is a characteristic of the more valuable metals, and particularly of silver and gold, while in contrast such an article as corn changes considerably in value from year to year.

From the foregoing examination of the requisites desirable in the material of money it is easy to deduce the empirical laws which the history of money discloses, since metals, as compared with non-metallic substances, evidently possess those requisites in a great degree. They are all durable, homogeneous, divisible and recognizable, and in virtue of these superior advantages they are the only substances now used for money by advanced nations. Nor is the case different when the decision has to be made between the different metals. Iron has been rejected because of its low value and its liability to rust, lead from its extreme softness, and tin from its tendency to break. All these metals, as well as copper, are unsuitable from their low value, which hinders their speedy transmission so as to adjust inequalities of local prices.

The elimination of the cheaper metals leaves silver and gold as the only suitable materials for forming the principal currency. Of late years there has been a very decided movement towards the adoption of the latter as the sole monetary standard, silver being regarded as suitable only for a subsidiary coinage. The special features of gold and silver which render them the most suitable materials for currency may here be noted. "The value of these metals changes only by slow degrees; they are readily divisible into any number of parts which may be reunited by means of fusion without loss; they do not deteriorate by being kept; their firm and compact texture makes them difficult to wear; their cost of production, especially of gold, is so considerable that they possess great value in small bulk, and can of course be transported with comparative facility; and their identity is perfect." The possession by both these metals of all the qualities needed in money is more briefly but forcibly put by Cantillon when he says that "gold and silver alone are of small volume, of equal goodness, easy of transport, divisible without loss, easily guarded, beautiful and brilliant and durable almost to eternity." This view has even been pushed to an extreme form in the proposition of Turgot, that they became universal money by the nature and force of things, independently of all convention and law, from which the deduction has been drawn that to proscribe silver by law from being used as money is a violation of the nature of things.

5. *The Introduction and Development of Coinage. The State and Money.*—The earliest metallic currencies passed by weight; they were, in fact, commodities, though used in a special way. The Hebrew records, as well as the Greek writers, bear witness to the prevalence of this primitive system. Thus, Aristotle, after explaining the circumstances that led to the invention of money, points out how it was at first defined simply by size and weight, although finally men went further and set a stamp on every coin to relieve them from the trouble of weighing it." (*Pol.* i. 9, 8.) Coinage systems have had a long period of growth, in which two distinct stages can be noted. In the first only the quality or fineness of the metal is denoted by the stamp, no attempt being made to fix the weight. The stamp, so to speak, acts as a kind of *hall-mark*. The cubes of gold employed by the Chinese may have been the earliest coins. Modern authorities accept the view of Herodotus that gold and silver coins were first used by the Lydians; the same author mentions that the first Greek coinage was at Aegina by Pheidon of Argos. In order to complete the invention it became necessary to certify the weight of metal in the coin as well as its fineness. A further result was the establishment of a regular shape for the purpose of preventing any tampering with the coin after its manufacture. Though various experiments in form were made, by the production of hexagonal and octagonal coins, the universally accepted shape came to be that of a flat circle, each side of which is stamped, as also in many cases the edge. The great number of the Greek city states afforded ample opportunities for experiment and competition, and rapid progress in the direction of securing good currencies was made. The improvement in the Greek coinages may be regarded as the consequence, and in some degree a cause, of their growing commerce. From Greece the art of coining was introduced into Italy by the Hellenic settlers and traders, and became one of the essential features of a civilized society. Progress, however, did not stop with the establishment of the institution of coined money. A number of practical questions had to be decided respecting the best way of overcoming the difficulties that certain technical problems presented. In spite of early experience, it has at times been suggested that the circular form might be replaced by some other, *e.g.* the square or oblong. Practice has confirmed the wisdom of the old-established shape. Another question was in respect to the limits of size that were most suitable for coins. Here the lower limit is prescribed by the convenience of the users. Coins that are easily lost, or picked up with trouble, such as the British threepenny piece and the American gold dollar, ought not to be issued. The determination of the upper limit presents greater difficulties. Very large pieces are hard to coin, and they give facilities for improper treatment by drilling holes and filling them up with cheaper metal, or even for the entire removal of the interior, the faces being preserved. The attractive appearance of large gold coins is no compensation for this danger. The English sovereign and, in silver, the half-crown seem to come near the upper limit of safe issue. The comparative wear of coins of different sizes must be considered. A long series of experiments, supported by ordinary experience, goes to show that the smaller coins wear more rapidly. The English mint in 1833 estimated the loss per cent. per annum at 2s. 6d. on half-crowns, 4s. on shillings, and 7s. 6d. on sixpences. There are accordingly reasons for adopting a medium size in preference to large or small coins. The actual coins issued have, of course, to be adapted to the requirements of the particular community. Even prejudices must be taken into due account. The designs employed in connexion with coinage have proved a fruitful field for the student of Numismatics (*q.v.*). From the monetary standpoint the aim of the design is to prevent either counterfeiting or the abstraction of any portion of the metal. For the former purpose careful execution in designing and the use of powerful machinery are the really effective safeguards. The latter is best obviated by protecting the edges by the process of milling, to which a raised inscription has sometimes been added. Great advances have been made in the organization of the modern Mint (*q.v.*) by the use of new appliances and scientific methods. The question of the proper alloy in coins has received a great deal of attention. As gold and silver are both by nature soft, some other metal, such as copper or tin, has to be added, in order to secure the necessary hardness. The English gold coins have an alloy of one-twelfth; the silver coins one of three-fortieths. Far more general is the alloy of one-tenth, which is probably due to the sentiment in favour of a decimal system; but at any rate is simple for calculations. There does not appear to be any strong technical reason for preferring either of these alloys to the other. The French mint authorities are in favour of their one-tenth; while the English ones adhere to the alloy of one-twelfth. There is agreement only on the point that a very small amount of alloy, *e.g.* that of one in seventy-two, as used in the Austrian ducat, does not give the requisite hardness.

A question of far more importance, both politically and economically, is that of the issue of money, and the power of the state in regard to it. In the ruder societies, where money was not sharply distinguished from commodities, no difficulty presented itself. Skins, shells or cattle were money—so to speak—by the force of things; and the same condition persisted as long as crude metals were employed. But with the introduction of coinage the idea of a regulating authority came into being. The necessity of enforcing contracts and the parallel system of penalties made it incumbent on the ruler and judges to provide due standards of payment. The combined effect of these influences was reinforced by the establishment of the rudimentary forms of state revenue, which made it a matter of interest to the ruler to provide a good medium of payment. Accordingly, with the origin of the organized state we find the coinage as a special prerogative of the king, though private persons often exercised the privilege of coining. The very large number of the autonomous cities of Greece, which possessed the right of issuing money, was the cause of the competition between different currencies, each having legal tender power only within its own city. In its practical outcome this "free coinage" system proved beneficial, for it compelled the maintenance of the true standard in order to gain wider circulation. With the establishment of larger states the control over the issue of money grew more stringent. In the later Roman Empire the right of coining was reserved to the emperor exclusively. After the fall of the empire the traditions of prerogative passed on to the medieval kings, a right carefully guarded by the English sovereigns. In France and Germany the principal nobles claimed this seignorial right, but in the modern state the regulation money has been definitely vested in the supreme authority, *i.e.* the sovereign.

One reason for the close connexion of money with the state is the fact that there is one attribute of currency which comes within the area of work specially allotted to the public authority. Money ought to have the power finally to close a transaction, *i.e.* to say it should be "legal tender." This "liberating power," as the French call it, might be regarded as one of the money functions. Those who look on money as a purely legal institution naturally take this view; it seems, however, better to take the economic conditions as the really fundamental ones. It is only on account of their economic effects that legal regulations require consideration. These effects are, indeed, very far-reaching. By prescribing the standard and amount of penalties, by their power of selecting the substances to be used as money, and by their frequent interferences with existing currencies, the governments of the world have guided—as well as very often disturbed—the normal course of development. What Aristotle regarded as the "unnatural" character of money is mainly attributable to state intervention. But it is important to remember that the sphere of governmental action in respect to money is limited. A currency system is never an arbitrary creation; it must grow slowly out of the habits and customs of the community, and must subserve its economic needs. No sudden change at the caprice of the state is likely to continue. Further, it is clear that no government can determine the results of its interference; these will depend on the existing conditions and will conform to economic law. Monetary history is rich in examples of the failure of legal enactment to direct the course of events, and of the disasters that have followed on the ill-advised measures of public authority.

One result of the close connexion of the state with the business of coining has been the establishment of regulations in reference to the expense of the process. As coins are manufactured articles it seems evident that a charge sufficient to cover the cost may rightly be imposed. Such a charge is described by the term Seigniorage (*q.v.*). It has in many cases been so fixed as to bring in a large profit to the government; but then it amounts to a depreciation of the currency; for the levy of a charge on coining is the same as the substraction of so much metal from the coins issued. English policy is peculiar in its adoption of gratuitous coinage of gold, an anomaly due in its origin to the prejudices of the mercantile doctrines, but defended on the ground of the convenience to trade from the equivalence of gold bullion and coin. The heavy seigniorage on the silver coins—at present over 60%—is a source of considerable profit; in some years exceeding £800,000. All other countries levy moderate charges on their gold coinages, and make profit on their silver issues, though in different ways. As it has become the duty of the state to maintain the currency in a sound condition, it has to deal with the question of its expense. This is composed of several elements, viz. (1) the cost of manufacture, just mentioned; (2) the loss through the wear which money undergoes in the work of circulating; and (3) the interest on the capital sunk in the monetary stock. A country with a metallic circulation of £100,000,000 incurs a loss of the interest which that amount of capital would produce by investment, *i.e.* at 4% £4,000,000. The expense is amply justified by the services that a good currency renders; but, at the same time, it proves the desirability of any economies that do not detract from efficiency. The great economizing agency is the use of representative money and the various forms of credit, in which so much of the latest advances consist.

6. *Representative Money; its Introduction and Development. The Mode in which Credit is used as Money.*—Economy in the employment of the precious metals is naturally suggested by ordinary experience; but the way in which states have profited by the expedient of depreciation affords a special inducement to follow what is practically the same course, and issue paper documents in place of the more costly metallic medium. In theory, as Ricardo explained, a paper currency is one in which the whole value has been appropriated as seigniorage. The cost of keeping a stock of valuable money is obviated, and the new instrument of exchange is supported by state authority. Here the action of economic conditions is instructively illustrated; for though a government can set up a paper currency, it is not within its power to prescribe its value. The quantity theory (§ 2) is confirmed by the inevitable decline in value when issue passes a definite point. The only effective mode of preventing depreciation is by limiting the amount of paper money to that of the metallic money previously in circulation. The easiest way to accomplish this is to leave the use of the paper currency optional by making it convertible into coin at the will of the holder. The amount of the circulation is thus automatically fixed by the action of the community. An evident disadvantage is the necessity of keeping an adequate reserve of coin to meet actual and prospective demands. For ideal security the whole amount of paper issue should be covered by an equal value of metal. In practice the reserve may be much smaller; but so far as it is required, it means a deduction from the gain of issue. The temptation to reduce the reserve to an inadequate amount and then to escape the difficulty by resorting to the expedient of refusing to pay coin for notes, *i.e.* making the notes inconvertible, has proved too strong for nearly all governments at times of pressure. The history of state dealings with paper money may broadly be described as a history of inconvertibility. Hard-bought experience has only now forced on the notice of governments the loss that follows from a disturbance of the standard used in ordinary payments. They are evident to all careful observers, and may be concisely summarized as consisting in: (1) the injustice to creditors through being paid in a much lower standard than that in which they lent; (2) the disturbance to trade, both domestic and foreign, by the fluctuations in the value of money; (3) the pressure on the working classes from the slower rise of money wages, in contrast with the quicker movement of the prices of commodities, resulting in a fall of *real* wages; and (4) the check to dealings in relation with the international money market, due to the risk of exchange fluctuations. The only gains are the temporary stimulus to certain branches of trade, and the advantage to the state by contracting a forced loan without paying interest.

The origination of paper money by state direction is the easiest to consider and explain. It does not follow that it is the most important or the earliest kind of representative currency. As W. Bagehot has pointed out, the real origin of economic institutions is often very different from the apparent one. In truth, representative money seems to have grown up out of the elementary contrivances of early credit. A claim could be expressed and transferred by a document, which might be used for facilitating exchanges. The rigid formalism of early law hindered the extensive use of this convenient machinery. It was not till the institution of *banking* that the coining of credit was made easy. Thus the bank-note comes into use, resting, not on the fiat of the state, but on the repute of the issuer. At this stage the history of the two distinct forms of representative money becomes mixed, owing to the control exercised over banks by government and to the fact that banking companies were in many cases the agents by which what was virtually state money was issued. There is, however, the fundamental difference that bank money finds its way into use through the ordinary system of granting credit; while government money is used in the purchase of commodities and the hire of services. The former, therefore, returns in a short time; the latter remains in circulation and displaces metallic currency. In the long controversy over the Bank Charter Act 1844 this distinction was brought into prominence. Since that date the extraordinary development of deposit banking in both Great Britain and the United States has furnished these countries with by far the most flexible form of currency yet known in the cheques that transfer claims on the capital held by the banking institutions. The confusion so often shown regarding the relation of credit to money is connected with this latest progress. When it is remembered that in its origin money is only an instrument to facilitate exchange—we might even say to render it possible—it follows that from its earliest to its latest form the ruling influence is the need of society for the best mechanism of exchange.

7. *Production and Consumption of the Precious Metals in their Economic Aspects.*—In considering various monetary questions it is essential to have some acquaintance with the economic

aspects of the production of gold and silver. The first point to which attention may be directed is the field over which production extends. At one time or other these two metals have been found in every continent. Asia Minor in early times possessed its goldfields, or rather auriferous sands. Ceylon also undoubtedly contained gold-mines. China and India both produced silver to a considerable extent. Egyptian remains show that gold was commonly known in that country, probably procured from Nubia and Abyssinia. On the opposite side of Africa, too, the name of Gold Coast shows that that metal was thence exported. The mines of Laurium in Attica were a source of supply to the Athenians, and were worked as a state monopoly. At an earlier date the Babylonian and Assyrian empires had each accumulated large stores of gold. The Phoenician importations of gold from the Red Sea coasts (Ophir) are known from Scripture. The Persian kings from the time of Darius levied tribute on all their provinces—in gold from India, in silver from the remaining districts, the larger part of which was stored up in the royal treasuries. This tendency of despotic rulers to accumulate treasure had all through ancient history important effects on the economic structure of society. At present it is quite natural to assume that the materials of money are distributed by means of international trade, and tend to keep at an equal level all the world over—an assumption which is in general well grounded, though an important exception exists. Ancient history presents a widely different set of forces in operation. Gold and silver were produced by slaves under the pressure of fear, and were drawn towards the ruling parts of the great empires; in a word, war, not commerce, was the distributing agency. From this condition of affairs it is easy to see that, whatever may be the reasons for assigning to cost of production a potent influence over the value of money in modern times (and grounds have been already advanced for the belief that its influence has been exaggerated), no such reasons then existed. The production of the precious metals was carried on in similar manner to the great buildings and other works of those periods, on non-economic grounds, and therefore produced quite different effects. The whole history of the Persian monarchy to its overthrow by Alexander (330 B.C.) shows that the hoarded mass of the precious metals continued constantly to increase. On the capture of Persepolis by the Grecian army an enormous treasure was found there, some estimates placing it as high as 120,000 talents of gold and silver (£27,600,000). All the temples, too, were receptacles for the precious metals, so that the stock accumulated at about 300 B.C. must have been very great. The only causes which tended to diminish the store were the losses arising from wars, when the various treasuries were liable to be plundered and their contents dispersed. There was therefore a more unequal distribution of the material of money than at present. The growth of the Roman dominion led to important results, since under their rule the Spanish mines were developed and became a leading source of supply. The great masses of treasure set towards Rome, so that it became the monetary centre of the world. The overthrow of the republican government and the peace which followed also affected the conditions of production. The inefficiency of the Roman administration made it advantageous to let out the mines to farmers, who worked them in a wasteful and improvident manner, while the supply of slaves was reduced, thus depriving the lessees of their principal agency for carrying on production. The result was a continuous decline in the store of money. W. Jacob has made an attempt to estimate the amount at the death of Augustus (A.D. 14), and arrives at the conclusion that it was £358,000,000. (*Precious Metals*, i. 225.) Without placing much value on this necessarily conjectural estimate, it is safe to assume that this period marked the highest point of accumulation.

The succeeding centuries exhibit a steady decline, though it is of course impossible to attach any value to even the most carefully guarded numerical estimates. The phenomenon which has since so often attracted notice—the drain of the precious metals to the East—began at this time, and was a subject of complaint by the Roman writers, while the stock of gold and silver being thrown into general circulation suffered from abrasion, and was more likely to be lost than when stored up in the royal treasure-houses and temples. These causes tended to depress the scale of prices, while the barbarian invasions produced a strong effect on the supply by drawing off the mining population and damaging the various erections used for working the mines. The conjectural estimate is that about A.D. 800 the total supply had been reduced to £33,000,000 (or about one-eleventh of what it had been at the death of Augustus). A new period in the history of gold and silver production may be fixed at this date. The Moors, now firmly established in Spain, began to reopen the mines in that country which had been allowed to fall into disuse. Other European mines also were opened, notably those of Saxony and the Harz Mountains, as well as the Austrian mines—the chief medieval sources of supply. The international system of currency, based on the pound of silver as a unit, which was introduced by Charlemagne, must have tended to economize the wear of the metals. We may therefore conclude that from this date (A.D. 800) the supply was sufficient to counteract the loss by wear and exportation, and accordingly regard the metallic supply as fixed in amount until the next change in the conditions of production, which was the result of the discovery of America. Though 1492 is the date of the first landing, yet for some time no important additions were made to the supply of money. The conquest of Mexico (1519) gave opportunities of working the silver-mines of that country, while the first mines of Chile and Peru were almost simultaneously discovered, and in 1545 those of Potosi were laid open. From this latter date we may regard the American supply as an influential factor in causing a continuous increase in the stock of money. The annual addition to the store of money has been estimated as £2,100,000 for the period from 1545 to 1600. At this date the Brazilian supply began. The course of distribution of these fresh masses of the precious metals deserves some notice. The flow of the new supplies was first towards Spain and Portugal, whence they passed to the larger commercial centres of the other European countries, the effect being that prices were raised in and about the chief towns, while the value of money in the country districts remained unaltered. The additions to the supply of both gold and silver during the two centuries 1600–1800 continued to be very considerable; but, if Adam Smith's view be correct, the full effect on prices was produced by 1640, and the increased amount of money was from that time counterbalanced by the wider extension of trade. At the commencement of the 19th century the annual production of gold had been estimated as being from £2,500,000 to £3,000,000. The year 1809 seems to mark an epoch in the production of these metals, since the outbreak of the revolts of the various Spanish dependencies in South America tended to check the usual supply from those countries, and a marked increase in the value of money was the consequence. During the period 1809–1849 the value of gold and silver rose to about two and a half times its former level, notwithstanding fresh discoveries in Asiatic Russia, which became considerable from 1823. The annual yield in 1849 was estimated at £8,000,000. The next important date for our present purpose is the year 1848, when the Californian mines were opened, while in 1851 the Australian discoveries took place. By these events an enormous mass of gold was added to the world's supply. The most careful estimates fix the addition during the years 1851–1871 at £500,000,000, or an amount nearly equal to the former stock in existence. The problems raised by this phenomenon have received careful study. The main features of interest may be briefly summed up. (1) The additional supply was almost entirely of *gold*, thus tending to produce a distinction between the two principal monetary metals and an alteration in the currency of bimetallic countries. Under this influence France, from being a silver-using, became a gold-using country. (2) The contemporaneous development of the continental railway systems, and the partial adoption of free trade, with the consequent facilities for freer circulation of commodities, led to the course of distribution being different from that of the 16th century. The more backward districts were the principal gainers, and a more general equalization of prices combined with a slight elevation in value was the outcome. (3) The increased supply of gold rendered a general currency reform possible, and made the use of a gold monometallic standard appear feasible. The movements for currency reform, as will be seen, all arose after these discoveries. (4) The change in the value of money, which may for the period 1849–1869 be fixed at 20 %, enabled a general increase of wages to be carried out, thus improving the condition of the classes living on manual labour. It may be added that the difficulty of tracing the effects of this great addition to the money stock is a most striking proof of the complexity of modern economic development. (5) The last point to be noticed is the very small influence exercised on the value of silver by the new gold. The gold price of silver in London rose only from 59¾d. per oz. to 62½d. per oz.—*i.e.* between 4 and 5%. Hardly had the gold discoveries of 1848–1851 ceased to produce a decided effect when new silver mines of unusual fertility came into working. During the period immediately succeeding the gold discoveries the production of silver remained at an annual amount of from £8,000,000 to £9,000,000. This amount suddenly, about 1870, increased to £15,000,000, and remained at that amount for the next five years. More than half of the supply came from new mines opened in Nevada. This increased supply was accompanied by a marked depreciation in the gold price of silver, though the prices of commodities in countries having a silver standard did not rise. The disturbances resulting from the combined effect of the new silver and the diminution in the annual output of gold which began about 1870 and continued for nearly twenty years were the cause of much controversy and led to the propounding of novel monetary theories. *Bimetallism* came into prominence; and the modes of relieving trade depression caused by the fall in prices were keenly discussed. Before any monetary adjustment took place the situation again changed in consequence of a renewal of the Australian gold production, soon followed by the great gold discoveries in South Africa. The annual output of gold, which had fallen below £20,000,000, in 1884 rose rapidly to £60,000,000, and in 1908 reached the prodigious figure of over £80,000,000, with the prospect of still larger yields in the near future. By this change the difficulties that had led to the agitations for "free silver" in the United States, and for "international bimetallism" in Europe and in India were removed, showing the close connexion between the production of the precious metals and the economic, especially the monetary, policy of all periods.

The modes of consumption of the precious metals—under which their use is included—are of equal importance with those of their production. Classed roughly, they come under three heads, viz. (1) their use as merchandise, (2) their use as money, (3) the "drain" to the East. With regard to the first, though precise data are not available, it may be said with some confidence that the demand for personal use tends, after society has made some progress, to decline in strength. The desire for adornment is not a keen one with most civilized persons; and, so far as it exists, is gratified in other ways than by using silver or gold. For purposes of manufacture their use is large and increasing. The second head is that with which we are principally concerned. It is evidently connected with the need for metallic currency; and this again depends on the level of prices and the monetary organization, including in the latter the banking system. Currency requirements still form the largest part of the demand for the precious metals. Under the third head a remarkable exception to the tendency towards the equal diffusion of the precious metals is presented. For nearly two thousand years the movement of silver from west to east has been noticed. Humboldt has made the ingenious remark that the course of these metals is in the opposite direction to that of civilization, and history supports his view. During the middle ages the chief Eastern products used in Europe were luxuries, such as silk and spices, and silver was sent from Europe to pay for them. Eastern trade increased, owing to the discovery of the passage round the Cape of Good Hope, and the flow of silver became greater. Special circumstances have from time to time influenced the movement. Thus, the new supplies of gold in the middle of the last century caused by their action on the bi-metallic currencies of Europe an acceleration in the flow, the amount exported between 1851–1862 reaching £110,000,000. To this drain of silver a more recent one of gold has been added. India takes year by year a considerable amount of gold bars, which may in the future have a monetary use, but up to the present appear to be hoarded or used for ornament. With the complete reconstruction of Eastern currencies that now seems probable there may come a decided change in the character of the demand. Another influencing condition is also undergoing change; the tendency to fix prices on a customary basis is bound to yield to the pressure of competition. The inevitable result will be to make the price level alter with each influx of money, and thus to limit the demand for bullion through the action of the exchanges.

One of the technical features of the production of the precious metals should be noted, in consequence of its economic effect. Gold has more frequently been found near the surface; silver is usually obtained by deep mining. It follows that the amount of the former metal produced depends more on accidental circumstances, in contrast to that of silver, which is affected by the standard of mining skill. The mines of Nevada were exceptional in their possessing both metals and in nearly equal value. The gold-mines of South Africa have come to be worked at deep levels and therefore are technically in the same class as silver ones. In fact, there is a pronounced tendency all the world over towards the system of capitalistic working.

8. *Review of the History of Some Important Currencies.*—Monetary theory requires to be elucidated by the constant reference to history; just as in turn the history of currency has to be interpreted by the aid of general principles. Each country has its peculiar problems, which call for special treatment; though at the same time there is no way of avoiding the operation of those economic conditions and forces that are to be found in all countries. The first decisive fact that emerges from the vast material presented by the history of money is the tendency at most periods towards deterioration. In the time of purely metallic currency debasement is the most serious danger; when representative money has come into being extravagant issues of paper are chosen as the readiest way of evading the limits of a sound currency. It is perhaps too extreme to say that monetary history is altogether made up of accounts of debasements and over-issues. The truth is better expressed in the proposition that there has been a constant struggle between the influences that make for deterioration and those that give support to the maintenance of a good currency condition. There is also the cheering circumstance that in spite of much popular ignorance there has on the whole been a steady improvement in the treatment of monetary systems. Expert knowledge has more effect in the later than in the earlier periods. The crude expedients of the Tudors would not be tolerated in modern England. There is much fuller recognition of the danger of over-issue in paper money; and this is accompanied by greater care in the treatment of credit institutions in their relation to the modern *media* of circulation. It is also noteworthy that mere popular agitation has lost a great deal of its power, as shown in the failure of both the "soft money" and the "free silver" movements in the United States. On the other hand the tendency to accept scientific methods is illustrated in the treatment of the Indian currency question.

Greek Currencies.—As already noticed the political conditions of Greek life supplied a varied field for monetary experiments. Unfortunately the details are very incompletely known, and the subject of Hellenic money has not been sufficiently studied from the economic side. Certain broad facts are prominent. The Athenian use of silver as the standard substance, coupled with the later employment of gold to serve for an extra or commercial currency, is a characteristic feature. The alteration of the standard by Solon appears in the light of an exceptional revolutionary expedient. It amounted to the creation of a new standard unit—the Attic—which was imitated by other states, *e.g.* Corinth. Only one doubtful instance of debasement can be found in the subsequent history of Athens. This honesty in respect to the monetary standard seems on the whole to have prevailed in the Greek states. Some despots, as Dionysius, issued adulterated coins, but these were isolated cases. The use of gold and silver in an amalgam, known as electrum, was an admissible device; it, however, had the evil effect of suggesting the use of poorer alloys.

Roman Money.—The history of money in Rome is rather different. Beginning with copper, the currency was changed into a double standard one by the introduction of silver (269 B.C.). Gold came in for commercial use with the extension of the Roman dominions, and copper was reduced to a token coinage. In the stress of the Punic Wars debasement was one of the financial devices of the magistrates. The conquest of the Greek territories brought about the regulation of their currencies. Silver was prescribed as the money substance. The establishment of the empire led to the definite concentration of the right of coining in the sovereign; though concessions were made in various localities, where the smaller coinages were allowed to continue. But the principal interest of the money of the Roman Empire is due to the remarkable way in which it illustrates the tendency of despotic and bureaucratic rule to lower the condition of good administration. A long course of debasement is the characteristic aspect of the currency system. "Under the empire," we are told, "the history of the silver coinage is one of melancholy debasement. The most extensive frauds in connexion with money were perpetrated by the Romans." The gold *aureus*, which in the time of Augustus was one forty-fifth of a pound, was under Constantine only one seventy-second of a pound. The alloy in the silver coins gradually rose to three-fourths of the weight. Plated coins came into extensive use. The practice of debasement was in accordance with the theories of the jurists, who seem to have regarded money as simply the creature of the state, *i.e.* the personal ruler.

Medieval Money.—After the overthrow of the Western Empire, though the invaders were in the condition of what has been called "natural economy," the state in which money has not come into being, they soon were disposed to carry on the Roman tradition, and their rulers adopted some form of silver currency. With the temporary revival of the empire under Charlemagne there comes the effort to found a general standard money on the basis of the silver pound. From this new starting-point it is possible to trace the course of some of the leading currency systems of Europe. For purposes of illustration it will be sufficient to sketch the movements in England and France, which are typical of the general course of monetary development. The systems of these countries are moreover remarkable (1) in the contrasts that they present to each other, and (2) in the widespread influence that they have exercised on the monetary arrangements of other nations.

English Monetary History.—The English currency begins with the pound of silver (troy weight) as the standard unit, subdivided into 20 shillings, each containing 12 pennies. The only coin at first in use was the silver penny. This system, in force before the Conquest, is the direct descendant of the Carlovingian system, and it continued without change until about 1276, when a slight depreciation was introduced by coining the pound into 243 pennies, instead of the original 240. This was the first of a series of changes, generally in the direction of lowering the weight of the coin. Two periods are remarkable for the operation of this tendency, viz. (1) the reign of Edward I., when the silver was debased by 20% in the period 1344–1351; and (2) the close of the reign of Henry VIII. and that of Edward VI., 1543–1552. In this short space of ten years the expedient of degrading the quality of the coinage by bringing the alloy up to three-fourths of the mass was practised for the only time in English history. The substitution of the pound troy for the Tower pound in 1527 was accompanied by a lowering in weight which far exceeded the gain from the higher weight of the new pound (5760 instead of 5400 grains). The reformation of the silver coinage under Elizabeth (1560), and its definite settlement in 1601 on the basis of coining 62 shillings from the pound troy also deserve mention. Turning to the gold currency, we find some gold pennies issued in 1257, probably in imitation of the issue of the Italian cities, which were due to the opening of eastern trade and the example of the Greek Empire, which had always retained its gold currency. The regular series of English gold coins begins in 1343, when Edward III. ordered the coinage of florins—the title is significant—at 50 to the Tower pound. The "noble" soon followed. The "sovereign" was first issued in 1489. But gold was treated as a commercial money, to be used as subsidiary to the standard silver. Its value was therefore varied from time to time to meet the difficulty that local bimetallism is certain to cause, in consequence of the undervaluing of one or other metal. During the 17th century the most noticeable monetary events are: the proposals for depreciation, of which the most remarkable was that of W. Lowndes (1652–1724), for lowering the standard by some 25%; the introduction of the guinea as the leading gold coin, and the frequent readjustment of the values of the two metals by proclamation. The great recoinage of 1696, carried out on the principles advocated by Locke, reformed the silver currency. In the 18th century the establishment of the guinea at 21s. by Newton's advice made the adoption of gold as the standard inevitable, since it was overvalued in an appreciable degree. The position of gold as the practical standard is clearly recognized by Adam Smith (1776) and is regarded as settled by Ricardo (1809). The full legal establishment of the present metallic currency took place in 1816, when the guinea made way for the present pound or "sovereign," and silver was formally reduced to the level of a token coinage, being slightly lowered by the coinage of the pound of silver into 66 shillings. Thus, by a course of development extending over 700 years, the English currency has been transformed from a crude silver standard system into one resting on gold, but employing both silver and representative money for the greater part of the actual work.

French Money: its Development.—Though the monetary system of Charlemagne soon disappeared in Germany and Italy, it continued in the part of his empire that became France. The extreme confusion of the time of his successors enabled the feudal lords to claim the right of coinage. No less than 150 seigneurs are said to have exercised this power at the accession of the first Capet. With the growth of the royal authority the freedom of private coining was restricted, in order to reserve to the Crown the profitable right of seigniorage. Unfortunately the legitimate profit from this source was not sufficient to satisfy the wants of the royal treasury. Therefore French monetary history is marked by a long series of debasements, extending from the time of Philip I. to that of Louis XV. (1060–1774). In sharp contrast to English policy the tampering with the currency was persistent, so that Louis IX. was looked on as quite exceptional. "In later days his management of the royal mint was always appealed to as the equitable standard for the observance of his successors." Yet in his time the livre had been debased to less than one-fourth of its primitive level. The Hundred Years' War presented the occasion for still further degradation. At the accession of Louis XI. (1461) the livre had been brought down to one-fifteenth of its original value. The 16th century is equally an age of depreciation, no less than nineteen occurring between 1497 and 1602. Again, in contrast to the English system, the absolute monarchy continued the process of debasing the standard under Louis XIV., and the livre was only one-half what it had been under Henri IV. At the Revolution the decline had proceeded so far that the livre had been reduced to one seventy-eighth of its primitive value. The new spirit of reform produced an entire change. The franc was substituted for the livre at the equation: 80 francs, 81 livres. In fact, until the establishment of constitutional government the French people had to depend on popular violence to procure any temporary reform in their currency. Since the Revolution the course of development has been essentially orderly and regular. All through the time of the *ancien régime* silver was the principal money and the standard, as the use of the word "argent" as a synonym for money shows. Just as England got a gold currency by overvaluing gold, so did France get a silver one by overvaluing silver. Indeed, it may be said that the different ratios chosen by the two countries necessarily caused a reciprocal drain, affording a good example of the action of local bimetallic systems with different ratios between the two metals. A further result from the comparison of the systems of England and France is the greater maturity of the former. England gained an honest currency before France; she led the way in the adoption of the gold standard, while in her treatment of representative money she has held as decided a priority. The difference in economic conditions in the nations in part explains the contrast. There is no doubt that in both cases a high degree of development has been reached. Finally, it should be remarked, that as England has worked out in practice the system of "composite legal tender," so has France, with its monetary allies, been the first to show effectively the operation of the "limping standard" (*étalon boiteux*). Each nation has thus supplied a type, which recent monetary changes give evidence of having been used as the pattern for other less advanced countries.

9. *Some General Questions respecting the Constitution of Money.*—The consideration of the history of currency systems naturally suggests the general problems that the more advanced countries have had to encounter. Of these, some may be described as *formal*, *i.e.* they relate to the arrangement and the definition of coinage and standards. Others are in essence issues of principle involving the most complicated theoretical doctrines, on which there is even yet sharp differences of opinion between competent students of economics. In some instances an intermediate class may be found, *e.g.* the question of subdivision of the coins does raise some difficult matters of application; though it clearly belongs of right to the group of formal questions. But the distinction is a valid one. Whether a country should adopt the "gold standard" or prefer a "bimetallic" standard is obviously very different from the elementary points about units and the different classes of coins. We will therefore begin by noticing some of the characteristics that are found in all modern currencies and some of which are implied in the idea of money. Thus it is true that every currency system must be based on a *standard unit of value* which consists of a "fixed quantity of some concrete substance defined by reference to the units of weight or space." The English unit, for example, is the *pound*, which consists of a definite quantity of gold (123·27447 grs. standard fineness) while the French unit is the *franc* (composed of 5 grammes of silver nine-tenths fine). It is not necessary, though it is usually the case, that there shall be a coin corresponding to the standard unit, all that is needed is that the current coins shall be multiples or submultiples of the unit, or at the least easily reducible to it. The Portuguese *rei* is too small to be coined, and the pound of silver that formed the unit of the

early English and French currencies was too large. Quite distinct from both the actual coins and the unit of value is the *money of account*, though in practice it is usually identical with one of them. In Russia in early times the *rouble* was an imaginary money of account not coined, while the copper *copeck* was the unit of value. Connected with the distinction between the coins and the unit is the highly important one between *standard* and *token* money, the former being of full power for discharging debts, and in the case of most systems only of equal value to the metal out of which it is made, while the latter is rated at a nominal value higher than that of its material. The silver and copper coinage in England and the smaller coins in the Latin union are only tokens; in the case of English silver coins, the cost value is less than 40% of the nominal one. The French tokens are made of inferior fineness (835 per 1000) to the full tender silver. Two restrictions are applied to token issues: (1) they are only legally available to discharge small debts—in England silver is limited to the payment of 40s.; (2) they can be coined only by the permission of the state. Thus in England the Bank of England is the state agent for the silver coinage. The limitations are evidently required to prevent the expulsion of standard money, and to avoid the flooding of the circulation with coinage that is not needed for the purpose of the limited exchanges to which it is confined. Intermediate between standard and token currency are those forms of coinage that are free from the first limitation, but restricted by the second. They have this further point of resemblance to tokens in that their nominal value is higher than that of their material—the French 5-franc pieces and the Indian *rupees* are prominent examples. Similarly, the analogy between representative money and token money is deserving of attention, and suggests the desirability of the latter being regarded as in some respects a fiduciary issue, for which the issuing authority incurs responsibility.

A class of considerations already referred to (§ 5) requires explicit notice here, viz. the influence of popular sentiment on the character and forms of a country's currency. The fact that money has to circulate amongst all classes of society makes it indispensable that it should be suited to the wants and even the prejudices of the users. Many curious instances of preferences for particular coins or special forms of paper money can be given. The Austrian Maria Theresa dollar of 1780 is a favourite on the African coasts and has been frequently reissued for use there. Reasons of convenience and of security combine with sentiment; as in the determined rejection of the U.S. "greenbacks" by the inhabitants of California during the inconvertibility of that currency. Recognition of the desires and tastes of the community is almost essential in carrying out any monetary reform. It is only by building on the habits and customs that have become established that improvements in the monetary system can be effectively completed. Not only is this careful observance of the disposition of the mass of society expedient; there is still greater need for taking account of the methods and interests of those sections of the business world that deal specially with money. A currency change that was bitterly opposed by the banking interest would certainly be difficult to introduce in either England or the United States; traders have great influence as to the forms of money that they will accept and facilitate the use of. In another aspect the study of the interest of dealers in the arrangement of the monetary system presents itself. One of the features that caused much surprise in the infancy of economic study was the disappearance of good coins from the circulation, while inferior ones remained in use indefinitely. To the first observers there seemed to be something perverse in the preference apparently shown towards debased or worn coins. In business transactions inferior articles are taken only at a lower price. The explanation is easily understood, when furnished; it consists in stating the difference between a commodity which is sought for its use, and money which is taken as merely a medium of exchange. Provided that coin is not too bad for further circulation it will be accepted without difficulty. Still less will there be any trouble if the difference is only in the relative value of two metals, such as silver and gold. The great majority of any population will give and take money without particularly observing it. It is enough if the coin conforms to the usual type. There exists, however, in all mercantile communities a class of dealers in money, who make a profit by selecting the best coins for exportation, or if two metals are in concurrent use, the coins of that metal which is undervalued in the proportion fixed. In the case of inconvertible paper issues the withdrawal is also for the purpose of hoarding to secure the profit expected when there is a high premium on bullion. The action of self-interest under these conditions produces an effect which has been briefly formulated in the statement "that bad money tends to drive out good money." The proposition has been styled "Gresham's Law" (*q.v.*). Abundant illustrations of its working are available. The establishment of the English *gold* currency and the French *silver* one in the 18th century, already mentioned (§ 8), is an effective one. Quite as good is the transition of France from the silver to the gold currency form after the great gold discoveries of the middle of the 19th century. In truth it may be said that most of the monetary transitions have been due to the operation of the force indicated in Gresham's Law. The importance of the law lies in the warning that it gives against the attempt to reform a degraded currency by the issue of better money. Such "operations of the mint are," in Adam Smith's judgment, "somewhat like the web of Penelope." The caution holds equally in respect to the reform of a depreciated paper currency or to an effort to force an undervalued metal into circulation. The success of so many monetary reforms in the last forty years has been in great measure due to the better appreciation of the working of the principle. Its aid can also be obtained by setting up the suitable conditions; while it can be counteracted through the use of the principle of limitation, so clearly expounded by Ricardo. Some of the constituent parts of the French and American currencies rest altogether on the maintenance of an overvalued coinage, along with one of higher value by the limitation of the quantity of the former to the amount that can be employed without expelling the remaining part of the circulating medium from monetary use.

Another part of the structure of any currency is the scale on which its accounts, and by consequence the degrees of its coins, are arranged. The pound, the shilling, and the penny in the older English system represented so many grades in the subdivision of value. All other currencies have the same need for divisions. The simplest scale would be what is called the "binary"; in which each coin is the half of the next higher, and double the one immediately below it. Most actual systems have series of coins on the binary scale. The penny, the halfpenny, the farthing; the 4s. piece, the florin, the shilling, the sixpence, the threepenny; at a higher level the sovereign, the half-sovereign, the crown, the half-crown, are English examples. The Latin and Scandinavian unions, as also Germany and the United States, have several binary coinage series. But no country adopts a purely binary scale. England in part retains the old "duodecimal" division in the relation of the shilling and the penny. Nearly all civilized nations have come to accept the system of *Decimal Coinage* (*q.v.*), though in their actual currencies they admit certain divergences from the strict decimal system. The convenience of having the monetary scale of accounts in accordance with the arithmetical scale will probably secure the ultimate victory of the decimal system everywhere, in spite of the objections to it on the ground of its having only two factors—2 and 5—as against the larger number of the duodecimal scale (2, 3, 4 and 6). The immense trouble involved in altering accounts and the difficulty of overcoming the hostility to change felt by the ordinary members of the community are the obstacles that prevent the adoption of the decimal system in England.

Connected with the composition of a currency and the scale on which it is based is the question of its relation to other currencies. From a very early time the conception of a money that should not be confined by a political limit appears to have existed. In fact until the state took over the control of money its more important forms had a wide diffusion. The talent, equated to the ox, is a prominent instance. Even when the city-state provided its particular coinage we can still perceive the circulation of the better coinages outside their legal area. The effect on the Greek currencies has been noted above (§ 8). Under the Roman hegemony and the empire that arose out of it there was the equivalent of an international currency in the wide circulation of the coinages adopted from the conquered states. Such coins as the drachma and the denarius were of general use in the then civilized world. In later times the Carolingian silver currency for a short period supplied an international medium, which vanished in the confusion of the middle ages. Owing to the rise of national governments money became a national distinction peculiar to each state. It is only in the last sixty years that the idea of international money has been revived in a practical form. Unfortunately the revival was speedily checked by the reaction in favour of nationalism that followed the Franco-German War (1870–71) and by the controversies as to the proper standard. (See BIMETALLISM and MONETARY CONFERENCES for further discussion of this topic.)

10. *Typical Currency Systems: their Evolution and Governing Principles.*—At first sight it appears that the systems of currency are almost infinite in their variety. They have grown up in different nations under the influence of local conditions and reflect the customs of the particular society. But, underlying these superficial differences, there are certain general principles that permit of a grouping into a small number of clearly marked types. The classification, though resting on logical grounds, is very largely in conformity with the course of historical development.

Better forms have come into being as social progress has become more pronounced; and further improvement may be expected in the future. The condition of things when money is coming into being is characterized by the weighing or measuring of the substances used for aiding the course of exchanges. It has therefore been called the system of "currency by weight." In strictness, it is better regarded as the stage before the introduction of real money; and thus outside the field of currency systems proper. The simplest system of currency seems to be that in which the state coins ingots of different metals and allows them to circulate without assigning any ratio for their respective values. Such an inconvenient form is not likely to be of long continuance; but it has sometimes arisen at a later time through the introduction of foreign coinages. Holland at the end of the 16th century, Turkey down to the present day may be given as countries approaching this state. The title of "currency by tale" is Jevons's apt denomination for such a currency system. The next form in logical order is that in which a single metal is definitely appointed as the sole standard money. In early ages this is the most natural arrangement, and it has, therefore, been widely adopted. Silver has been the metal generally used in this way; as the instances previously given (§ 8) prove. The title of "single legal tender" system is the obvious one for this form. With the growth of transactions a difficulty soon presents itself. If the chosen metal is not of high value it is cumbrous for making large payments; if on the other hand its value is high, it is unsuitable for use in small transactions. Hence there almost inevitably follows the use of other metals, which are better suited for certain particular uses. Thus silver is at once too heavy and too light. To pay £1000 in silver at its present value would take 800 ℔ troy, while a silver penny would be under the convenient limit of size. Partly for these reasons, but also to a large extent through the persistence of currency by tale, we find that along with the standard money other kinds are brought into or retained in use. Copper long survives beside silver; and gold is employed for the more important commercial transactions. Public convenience leads to the valuation of these subsidiary forms of money, and in this easy manner another currency system—that of "multiple legal tender"—comes into being. Though, theoretically, several substances might be valued for use as money, in practice some kind of bimetallism is used, and generally gold and silver are the constituents of the system. Thus for over three centuries England had a currency in which the values of gold and silver were fixed from time to time by royal proclamation. France and the United States, as well as many other countries, have had long experience of national bimetallism. The great problem in such a form of currency has always been that of keeping the two metals in effective circulation. As the values of the precious metals fluctuate, the principle of Gresham's Law is exemplified by the expulsion of the undervalued one. Each change in the conditions of production or in the ratios fixed by other countries tends to disturb the balance and is harassing to trade. Local or national bimetallism comes to be unsustainable, and is replaced by other currency types. The most remarkable is that known as the "composite legal tender" system. Its object is to combine any advantages of multiple legal tender with the maintenance of the single standard principle. One metal is selected as the standard and is legal tender to any amount; other metals are utilized for the purpose of token currency. Thus in the system of the United Kingdom gold is the only standard coinage; but silver and copper are employed for the lower coins and for smaller payments. The establishment of this ingenious arrangement is rather the outcome of the circumstances that governed the English monetary situation in the 18th century than any refined considerations of theory; but its justification on grounds of principle is furnished in Lord Liverpool's *Coins of the Realm* (1805). The extent to which the system has been copied by other nations and the stability of the English currency are strong confirmations of its merits as a solution of currency difficulties. Though the composite legal tender system has been a decided success, it does not follow that it supplies the only mode of dealing with the troubles that attend on the use of the local double standard. Other methods have been evolved from the monetary experiences of France and India, which take distinct forms according to the special features of the case. There is the currency system known as the "limping standard," the essence of which is the concurrent use of two metals, one being overvalued and coined only by state authority. The quantity of this favoured metal is necessarily limited in amount, to avoid depreciation or the ejection of the other metal from the circulation. It, however, has the position of money in the fullest sense, in that it is legal tender for any amount. The 5-franc pieces issued by the Latin union are the best known specimen of such coinage. In this case also the origin of the system was not theoretical, it was the result of the fall in the value of silver and the fear entertained by the French government that gold would be displaced by the cheaper metal. The temporary expedient of limiting the coinage of standard silver has developed into the maintenance during more than thirty-five years of the limping standard, which derives its name from the shortness of one limb of the currency body. Equally suggestive for monetary theory is another phase or system, usually described as the "gold-exchange standard" system, in which the ordinary currency is of a metal coined only by the state, and so limited as to keep it in a prescribed value ratio to another metal (gold) which does not circulate, but acts as the *standard* of value. This variation on the limping standard has been produced by the effort of the Indian government to meet the embarrassment caused by the continuous fall in the gold value of silver. Under the pressure of failing revenue and of persons suffering from the rupee depreciation in gold, the limitation on silver coinage was first enacted (1893); to be followed some years later (1899) by the establishment of gold as the standard, with a definite parity assigned for the state silver issues. The success of the Indian experiment—for such it avowedly was—has led to its imitation by the American administration in the Philippine Islands and by Mexico. It may be looked on as the natural product of the condition in which the single legal tender system is proving unfit, while the material for the composite legal tender system is wanting. The employment and theoretic explanation of these methods of currency adjustment mark the greatest advance made in monetary science and practice in recent years. Whether the limping, or the gold-exchange standards will be permanent forms is difficult to determine; but they are beyond doubt of much importance in meeting the risks of a period of transition. In any case they are entitled to recognition as distinct forms of currency organization, resting on a scientific basis.

The types presented by purely metallic currencies can be considered by themselves for the purpose of theoretical exposition. In actual working they are now affected by the existence of representative money. The state issues paper money which may be either convertible or inconvertible, or if it refrains from so doing, the banks take up the task and supply a medium of exchange in the form of notes, or by a later development through providing for the use of cheques by their customers. An inconvertible paper currency has some pronounced affinities with overvalued metal; a duly regulated issue of this kind is quite on the lines of the gold-exchange system, and the difficulties of the two forms are very similar. But, just as the cruder systems of metallic money have gradually given way to the higher ones, so it may be said that the grosser forms of mismanagement in representative money are being removed, notwithstanding the recurrence of such monetary crises as that of 1907 in the United States. The great instance of government paper money is the United States notes, known, as "greenbacks," which are fixed at the amount of $346,681,016. The most prominent case of bank issue of notes is that of the Bank of France, with somewhat over £200,000,000 in circulation. Examples of the cheque currency are more difficult to state in quantitative shape; as the constituent parts are continually being created and cancelled, but the clearing-house returns give some idea of its extent in England. The figure for 1909 was

£13,525,446,000. It seems highly probable that the next stage in improvement will be the extension of currency based on credit, after the Anglo-American pattern, to the other commercial countries of the world. But this movement can only be slow, it will not affect Eastern countries. For a long time they will remain in the metallic currency stage, with the moderate use of a guaranteed note circulation.

There are several plans which have been advocated as superior to any of the systems actually in use. Most of these schemes are undeserving of notice; a few, however, claim attention on the ground of theoretical or practical importance. The most conspicuous is that known as "international bimetallism," which was designed to obviate the evils said to result from the demonetization of silver and the overflow of the established ratio between the precious metals. Its central idea was the creation of a monetary league, composed, if not of all, at least of the leading states (the larger the number the better), the members being bound to coin any amount of gold and silver at an agreed ratio. By such an agreement an adequate field for the use of both metals would be provided, and fluctuations in the relative value of silver and gold would be completely prevented. The expulsion of the cheaper metal would be impossible, owing to the absence of any place to which it could be driven. Variations in the production of the precious metals would act on both metals, not on one. Another plan for meeting the same set of difficulties is the composition of the monetary standard by taking assigned amounts of both metals in combination as the unit—say 1 oz. of gold with 10 oz. of silver. The title "symmetallism" has been given to this ingenious mode of trying to obtain a more stable standard than that afforded by the employment of a single metal. Amongst the many devices that the use of paper money has suggested the most noticeable are those that aim at the replacement of metallic money by some other basis. The socialist conception of a "labour note" may be paralleled by the idea of "commodity notes," resting on a development of the clearing system. Viewed from the practical standpoint it may be said that the double standard in any form is condemned by the course of events; it has been defeated by the gold standard. In respect to the other proposed methods there is the almost insurmountable difficulty of making them in any way sufficiently popular to overcome the resistance that they must necessarily encounter. This criticism holds good, quite apart from the objections of principle to which they are all open, in very different degree it is true. The influence of custom in relation to money can never be set aside. For this reason it is certain that very gradual change is the only possible kind of monetary reform that can hope for success. It is essential to preserve as far as possible the old surroundings and avoid the intrusion of novel devices. The adoption of what Sir R. Giffen has styled "fancy monetary standards" is reserved for a distant future.

In the course of the development of monetary systems important theoretical problems have presented themselves. For the middle ages the great question was the best mode of securing an honest metallic currency. At the beginning of the modern national states the problem of keeping a parity between silver and gold was the most serious issue which each state attempted to solve independently. With the rise of credit there followed debate on the proper management of paper money in its various forms, which has not yet been completely closed. But the tendency in the last fifty years has been to concentrate attention on the meaning and due constitution of the monetary standard. In particular, the difficulties that result from an alteration in general prices, and the inconvenience to foreign trade from different currency standards have been exhaustively considered. It is therefore desirable to present in a concise form what appears to be the outcome of these discussions. The first established conclusion is the impossibility of obtaining an absolute and invariable standard. The best that can be hoped is a near approximation by balancing the elements of fluctuation. The construction of the most suitable monetary system is a work of practical adjustment. The influence of the actual conditions, which has been already emphasized, helps to indicate the limits of profitable inquiry. In respect to the metallic basis the choice is between the single standard—gold or silver, and some combination of these. The single standard of silver can be set aside, though it has had influential supporters. On the other hand the only combinations that need be considered are those indicated above by the titles "bimetallism" and "symmetallism."

The theory of the gold standard rests on the principle that one metal is a better criterion for measuring values than two, since the fluctuations that occur by the substitution of one metal for the other are certain to be disturbing. There is the further difficulty that no ratio can be permanently fixed between two metals, as their values must vary with the alterations in production. The inherent simplicity, and, so to speak, "naturalness," of the single standard is best realized by embodying it in gold, which is universally desired, of high cost and yet found in sufficient amount to discharge the money work of the standard. The verdict of history is appealed to as confirming the theoretic presumption, for gold has been gaining ground from century to century. The struggles to reverse this process have only made it more pronounced (see MONETARY CONFERENCES). Most of the objections to the gold standard rest on ideas which are the support of other economic fallacies. The attempts to supersede it involve the rejection of the rule of economic law. The foundation of the doctrine of "bimetallism" is the theory that the value of money is determined, not simply by cost of production, nor by unregulated supply and demand, but by the action of regulated demand, in conjunction with the actual conditions of production. States are the demanders of metal for monetary use, and by adjusting that demand they can powerfully influence the course of production, especially as the cost at which either

gold or silver is obtained varies with the productiveness of the poorest mine in working. Thus by directing consumption, states are controlling production, and therefore—within limits—fixing the relative value of the two metals. This power has been shown in the stability of the ratio during the continuance of the French double-standard (1803–1873). The possibility of maintaining a given ratio being thus established, the argument proceeds to show the advantages of the system. (i.) It secures the concurrent use of the precious metals and avoids throwing all the money work on gold. (ii.) Greater stability in value may be expected, since the fluctuations of either metal will be compensated by those of the other. At the worst the variation can only be as great. (iii.) The larger stock of money tends to keep up prices to the benefit of trade; for falling prices hamper production. (iv.) The fixed ratio provides a stable par of exchange between silver-using and gold-using countries; though universal bimetallism would remove this distinction. (v.) The establishment of a world-currency would be facilitated by allowing both metals a well-defined relation. This enumeration of the heads of the "bimetallic" case shows that its working depends on the area of its operation. It must be "international" and the states composing the union must be "great powers" in the monetary sense. Otherwise, their action would be comparatively ineffective. The crucial difficulty has been the determination of the common ratio. The risk of failure in carrying out the policy has proved a deterrent to such great powers as England and Germany, who are in possession of the gold standard. On the theoretic side the chief weakness of bimetallism has been its failure to supply any clear account of the limits within which states can regulate the ratio of gold to silver. If the ratio 15·5:1 can be set up why should not the ratio 100:1, or that of equality? Its practical failure has resulted partly from political conditions, partly from the removal of most of the difficulties which it was

* Inconvertible paper currency.

---

[1] Present system introduced in 1894, in place of the system adopted in 1870. The Maria Theresa dollar is only used as a commercial money in Levantine trade.

[2] The system of the Scandinavian union came into force on the 1st of January 1875. It is based on gold monometallism.

[3] The coinage system of France came into force on the 6th of May 1799. It was extended to the countries forming the Latin union in 1865; it has been adopted by Greece, Rumania, Servia and Spain. It is the most widely extended system in Europe. The Austrian 8 and 4 gulden pieces were equivalent to the 20 and 10 franc pieces. In 1879 it was estimated that the system was used by populations amounting to 148,000,000. In its origin a double standard (with ratio of 15·5:1) it has become a limping standard by the limitation of the silver coinage. The unit is the same value all through the union, but receives different names in different countries. The titles are: in France, Belgium and Switzerland, *franc* and *centime*; in Italy, *lîra* and *centesimo*; in Greece, *drachme* and *lepta*; in Rumania, *lĕu* and *ban*; in Servia, *dinar* and *para*; in Spain, *peseta* and *centesimo*.

[4] The German coinage law came into force on the 1st of January 1875. It was modelled on the English system, but it is only in the last few years that the old silver has been completely withdrawn.

[5] The Dutch standard has been changed more than once. In 1847 a silver standard was introduced, and retained till 1872, the unit being the silver guilder. In 1875 the free coinage of gold was decreed; silver coinage having been restricted since 1872. Thus the limping standard is in force.

[6] The nominal standard of Portugal is gold. The English sovereign is legal tender at 4500 reis.

[7] The Russian currency until 1897 was nominally a silver standard one; but really was inconvertible. The currency was improved in 1885; and in 1897 the gold standard was adopted, provision being made for the withdrawal of the paper money. Finland, which had a currency on the French model, is now being compelled to accept the Russian currency.

[8] The Spanish coinage was assimilated to that of the Latin union in 1871. Spain, differing from the other countries of the group, coins a 25 peseta piece.

[9] The Medjidie coinage was introduced in 1844. English sovereigns circulate at 125 piastres; 20 franc pieces at 100 piastres.

intended to meet by the subsequent economic development. The proposal for a joint standard formed by using a unit in which the two metals are combined has the advantage of escaping the risk of failure to maintain the ratio, for it makes the employment of both silver and gold essential. Its influence in causing stability is also likely to be greater; but it is open to the danger that a shortage of one metal would not be compensated by the abundance of the other. The further advantage that it does not need international agreement (for each country could settle its own combination) is counterbalanced by the strangeness of the plan and by its necessitating the use of representative money. The suggestion of "goloid" coins on the model of the Greek electrum would hardly be acceptable.

11. *The Present Money Systems of the World: Changes of the last Half Century.*—The facts as to the money of the leading countries of the world are given in Tables II. and III. It is, however, necessary to explain the way in which this position has been reached by the reforms of the last fifty years. Since 1860 the alterations in standards and in coin denominations have been of a very extensive nature. England is one of the

* Inconvertible paper currency.

---

[1] Until 1906 there was no mint in Canada. English and American coins circulate. The standard is gold (£1 = 4·866 dollars). There were formerly different methods of counting, viz. English sterling, Halifax currency and Canadian sterling; the respective ratios being 100: 120: 108.

[2] The Mexican currency has been entirely altered in its standard by the legislation of 1905. The gold-exchange system has been brought into force. The old-established dollar, which is called *piastre*, is reduced so as to represent a ratio of about 33·1.

[3] The dollar was introduced in 1787 as the unit. In 1792 the ratio of gold to silver was fixed at 1 to 15. This valuation underrated gold, consequently silver became the standard. In 1834 the ratio was altered to 1 to 16, and it was again changed in 1837. In these changes gold was overrated, and silver was driven out of circulation. This led, in 1853, to the reduction of the metal in the silver coins, which therefore became a token-currency. The suspension of cash payments took place in 1861. In 1873 silver was demonetized, and gold became the standard. In 1878 the "Bland Bill" was passed, making the silver dollar a legal tender, but confining its coinage to the executive, and fixing the amount at from two to four million dollars per month. The difficulties that resulted from this measure led to the Sherman Act of 1890, providing for the coinage of silver to the annual amount of 54,000,000 oz. Owing to the critical situation created by these efforts to aid silver, the repeal of the Sherman Act was carried in 1893. Since then the chief problem has been to maintain an effective gold reserve.

[4] The Argentine currency is, in practice, one of inconvertible paper. The gold coins were altered in 1881. The old South American *onza* weighed 27 grammes, was 875 fine and worth £3, 4s. 6d.

[5] The Brazilian currency is greatly depreciated. It is derived from the Portuguese.

[6] The Chilean coinage was reformed in 1895, when the gold standard was adopted, and the system brought into relation to the English one. Two Chilean *Condors* (20 peso pieces) being equal to £3.

[7] In 1904 Colombia adopted the gold standard by taking the equivalent of the U.S. dollar as the unit; but the inconvertible paper is the main currency; and the old coins pass as commercial money.

[8] After attempting a parity with the Latin union, and passing through a period of inconvertible paper, Peru has adopted the English gold standard and coinage, but keeps her own silver denominations.

[9] The silver standard was prescribed in India in 1835, with the use of the gold mohurs. The latter was demonetized in 1853. In consequence of the fall in the gold value of silver, the Indian mints were closed to the coinage of silver, otherwise than by the government, in 1893. The amount of currency was so limited as to bring the rupee to the value of 1s. 4d. On the realization of this position, English sovereigns were made legal tender at the ratio of 15 rupees = 1 sovereign. India has, by these measures joined the class, now becoming numerous, of gold-exchange standard countries.

[10] The old Japanese currency consisted of gold cobangs and silver itzibus, with a ratio of 4 to 1. This antique system was replaced in 1871 by a double-standard one on the French plan, the ratio being 16·17: 11. The system passed first into one of silver monometallism; and then became one of inconvertible paper. The great reform of 1897, aided by the Chinese War indemnity, placed the currency on the gold basis.

few countries that has not found change desirable. France has reorganized her token coins (1864), entered into the Latin union (1865) and adopted the limping standard in 1874. Germany has completely transformed the monetary system hitherto existing in the German States (1873). The Scandinavian union has been set up (1875). Holland has changed her system more than once. Still later, Austria-Hungary (1892) and Russia (1897) have come over from the silver standard with the practical use of inconvertible paper to new currencies on the gold basis. In America the United States, after a series of monetary experiences, has made the gold dollar its standard unit, though the silver complication still exists. Mexico has succeeded in establishing a gold-exchange standard at such a ratio as to induce the import of gold. British India has had its rupee currency put into relation to the English gold unit, and has been followed by the Straits Settlements. Japan first abandoned its ancient currency (1871). It then adopted a double standard system which became in practice a silver one and later passed into inconvertible paper. Finally, it has (1897) established a composite legal tender system on the gold basis. The Dutch Indies have the gold-exchange standard on the same plan as British India.

Remarks.—In addition to the tabular statements, the following points respecting the currencies of less advanced countries may be indicated. Though there is a tendency to establish the money of the mother-country in colonies, some of the British possessions, acquired by conquest, have kept their former currency. There has been a widespread movement in the backward countries of the world towards reforming their money; chiefly by setting up some line of connexion with the gold standard. In South and Central America the dollar has been retained as the unit; but the movement for co-ordination with the French system has ceased. The English standard has been preferred as a model by Chile and Peru. In Asia the currency of the Philippines has been reorganized under American control. China is considering monetary reform, and Siam has made progress in the direction of the gold-exchange standard. Probably the most defective currencies are now those of Turkey and her tributary states.

BIBLIOGRAPHY.—The literature on the subject of money has been well described as "almost measureless." The list of writers who have contributed to it begins with Aristotle, and includes such famous names as Copernicus, Locke and Newton. A full enumeration would fill a volume of no slight size. All that can be done here is to give a short classified list of the most serviceable books.

I. Economic text-books: English and American—J. S. Mill, *Principles of Political Economy* (London, 1848; new ed. by Ashley, 1909); Sidgwick, *Principles of Political Economy* (London, 1883; 3rd ed., 1901); J. S. Nicholson, *Principles of Political Economy* (3 vols., London, 1893–1901); F. A. Walker, *Political Economy* (New York, 1883; 2nd ed., 1887, often reprinted); A. T. Hadley, *Economics* (New York, 1896); E. R. A. Seligman, *Principles of Economics* (New York, 1905); H. R. Seager, *Introduction to Economics* (New York, 1904; 3rd ed., 1908). French: M. Chevalier, *Cours d'économie politique* (vol. iii. "La Monnaie," Paris, 1850); P. Leroy-Beaulieu, *Traité d'économie politique* (4 vols., Paris, 1896); C. Gide, *Cours d'économie politique* (Paris, 1909). German: H. Mangoldt, *Grundriss der Volkswirtschaftslehre* (2nd ed., Stuttgart, 1871); G. Schonberg, *Handbuch der politischen Oeconomie* (Tübingen, 1882; 4th ed., 1904); G. Schmoller, *Grundriss der allgemeinen Volkswirtschaftslehre* (Leipzig, 1900–1904). The Dutch work by N. G. Pierson has been translated into English with the title *Principles of Economics* (London, 1902).

II. Special treatises on "Money": W. S. Jevons, *Money and the Mechanism of Exchange* (London, 1875); F. A. Walker, *Money* (New York, 1878); J. S. Nicholson, *Money and Monetary Problems* (London, 1888; 6th ed., 1902); C. A. Conant, *The Principles of Money and Banking* (2 vols., New York, 1905); A. Arnaune, *La Monnaie, le crédit et le change* (Paris, 1894; 2nd ed., 1902); A. de Foville, *La Monnaie* (Paris, 1907); C. Knies, *Geld und Kredit* (Berlin, 1873–1879); G. F. Knapp, *Staatliche Theorie des Geldes* (Leipzig, 1905).

III. Works on special questions: See BIMETALLISM; BANKING; and MONETARY CONFERENCES for writings on the problems of the standard and depreciation. For the history of money—F. Lenormant, *La Monnaie dans l'antiquité* (Paris, 1876); W. A. Shaw, *History of Currency, 1252–1894* (London, 1895). For the history of the English currency, besides the works on the numismatic side—Lord Liverpool, *Coins of the Realm* (1805; reprinted 1880). For America—W. G. Sumner, *History of American Currency* (New York, 1874). On the production and consumption of money materials, W. Jacob, *Production and Consumption of the Precious Metals* (2 vols., London, 1831); and A. Del Mar, *History of the Precious Metals* (London, 1880). Technical details in Tate's *Cambist* (many editions).

(C. F. B.)

MONEY-LENDING, the lending of money on usury (*q.v.*). The business of the professional money-lender is one which, as tyranny and abuse are likely to appear, all countries have at different times endeavoured to regulate. In England the lessons of experience have shown that the abuses of this business are best regulated by a system of registration coupled with relief to debtors against harsh and unconscionable bargains. Other countries however still appear to cling to the belief that it is wisest to fix a maximum rate of legal interest. Thus in Germany the commercial code fixes the legal rate of interest on commercial transactions at 5%. Moreover in that country traders can demand interest on commercial debts from the day on which the debts fall due. In France, again, the Code fixes the rate of interest on ordinary loans at 5%, and on commercial transactions at 6%. In the United States of America the law relating to the lending of money on usury varies in the different states. All the states have what is called a "legal rate" of interest; and when no rate of interest is specified in the contract between the parties, there is a presumption that the borrower has agreed to pay the legal rate. This legal rate varies from 5% in Louisiana to 8% in Wyoming; in the Eastern states it is generally 6%. Some of the states have usury laws giving relief to borrowers in cases where circumstances have compelled them to agree to extortionate rates; but other states have no such laws, except that a contract in writing is invariably required in all cases where the "legal rate" is exceeded.

Practically every form of investment in which a man is capable of indulging involves the lending and borrowing of money, the interest exacted being the profit which the lender receives for the use of his capital. The existence of the professional lender, as apart from the ordinary facilities for borrowing money on good security, is obviously due to the fact that it is not every borrower who is in a position to give good security for a loan. Where the security is bad the market is narrowed; the individuals who are prepared to lend the money on merely personal security require a high rate of interest.

The first people to practise the profession of money-lending in England regularly were the Jews, and the business has remained largely in their hands, though they are in the habit of trading under assumed names. The Norman and Angevin kings were fully alive to the advantages which accrued to the people through borrowing at usury from the Jews, but they were also alive to the advantages which they themselves were able to reap by extorting from the Jews the wealth which the latter had acquired from the people. The Jews were regarded as the king's serfs, and squeezing them was but a popular form of taxing the people. Indeed in the reign of Henry II. the Scaccarium Judaeorum was established as a separate branch of the exchequer and used for the purpose of filling the royal coffers. The English people on the other hand were not so prone to foster the money-lending business. Sections 10 and 11 of Magna Carta provided that when a person died owing money to a Jew no interest should accrue during the minority of the heir, and further that the widow should be entitled to her dower, and any children who were minors should be provided with necessaries before the repayment of the loan. Then followed a large number of statutes known generally as the Usury Laws (see also USURY). The first of these was passed in 1235 (20 Hen. III. c. 5). The acts were directed to restrain the lending of money at usurious rates. The earlier ones in some cases prohibited the lending of money on usury at all, as in a statute of Jewry of the reign of Edward I.; but the later statutes were chiefly confined to limiting the rate of interest. Thus 21 Jac. I. c. 17 declared void all contracts where the interest was more than 8%. In 1818 a select committee of the House of Commons was appointed to consider the Usury Laws and in 1841 a similar committee of the House of Lords was appointed. As a result an act was passed in 1854 (17 & 18 Vict. c. 90) whereby all the existing laws against usury were repealed.

The question whether any interest is payable or not, and also the amount of such interest, depends on whether the parties to the transaction have expressly or impliedly agreed to the payment of interest by the borrower; for apart from such agreement no interest can lawfully be demanded on a loan.

Although in general there is no limit on the amount of interest which a borrower may agree to pay, equity has always been ready to grant relief from unconscionable bargains. This equitable relief is still available, though it is not so wide as the relief now given to borrowers under the Money-lenders Act 1900. This act provides that where proceedings are taken in any court by a money-lender for the recovery of money lent, and there is evidence which satisfies the court that the interest charged on the loan, or the amounts charged for expenses, inquiries, fines, bonus, premium, renewals, &c., are excessive, and that in either case the transaction is harsh and unconscionable, or is otherwise such that a court of equity would grant relief, the court may reopen the transaction and take an account between the money-lender and the person sued, and may, notwithstanding any statement or settlement of account or any agreement purporting to close previous dealings and create a new obligation, reopen any account already taken between them and relieve the person sued from payment of any sum in excess of the sum adjudged by the court to be fairly due in respect of such principal, interest and charges as the court, having regard to the risk and all the circumstances, may adjudge to be reasonable.

The Money-lenders Act of 1900 was passed in consequence of grave abuses which had arisen. It had been the practice of a certain class of lender to trade under a variety of names; so that under one name the same individual would lend money to a person who borrowed from him under another name; the second loan would be spent in liquidating the first, and the borrower finding it always easy to obtain more money would continue borrowing until he became hopelessly involved. The act struck at the root of this pernicious system by providing that every money-lender, as defined by the act, must register himself as such, under his own or usual trade name, and in no other name, and with the address, or all the addresses if more than one, at which he carries on his business of a money-lender. If a money-lender fails to register himself, or if he carries on a money-lending business otherwise than in his registered name, or in more names than one, or elsewhere than at his registered address, he is liable on summary conviction to a fine, not exceeding one hundred pounds. For the purposes of the act "money-lender" is defined as including every person whose business is that of money-lending, but it does not include pawnbrokers, in respect of business carried on by them under the Pawnbrokers Act, Registered Friendly, Loan or Building Societies, coporate bodies incorporated or empowered by special act of parliament to lend money, persons *bona fide* carrying on the business of banking or insurance, or *bona fide* carrying on any business not having for its primary object the lending of money, or bodies corporate for the time being exempted from registration by order of the Board of Trade.

The act is not confined to providing for the registration of money-lenders and for the reopening of harsh and unconscionable bargains. A check is placed on false representations and promises made with the intention of inducing a borrower to enter into a loan transaction. If any money-lender, or any manager, agent or clerk of a money-lender, or any person being a director, manager or other officer of a corporation carrying on the business of a money-lender, by any false, misleading or deceptive statement, representation or promise, or by any dishonest concealment of material facts, fraudulently induces, or attempts to induce, any person to borrow money or to agree to the terms on which money is to be borrowed, he is declared by the act to be guilty of a misdemeanour and is liable on indictment to imprisonment with or without hard labour for a term not exceeding two years, or to a fine not exceeding five hundred pounds, or to both.

The act further provides that if any one for the purpose of earning interest, commission, reward or other profit sends or causes to be sent to a person whom he knows to be an infant any circular or other document which invites the person receiving it to borrow money or to apply to any person or at any place with a view to obtaining information or advice as to borrowing money, he shall be liable, if convicted on indictment, to imprisonment with or without hard labour, or to a fine, or to both imprisonment and fine. If any such circular or document sent to an infant purports to issue from any address named therein or indicates any address as the place at which application is to be made with reference to the subject matter of the document, and at that place there is carried on any business connected with loans, every person who attends such place for the purpose of taking part in or assisting in the carrying on of such business will be deemed to have sent or caused to be sent such circular or document, unless he proves that he was not in any way a party to and was wholly ignorant of the sending of such document. Moreover, by section 5 of the Money-lenders Act 1900, where any proceedings are taken against the senders of these circulars to infants, if it is proved that the person to whom the document was sent is an infant, the person charged will be deemed to have been cognisant of the fact unless he proves that he had reasonable grounds for believing the infant to be of full age. Under the act of 1892 this shifting of the burden of proof only occurred if the circular had been sent to any person at any university, college, school or other place of education.

As for the recovery of money lent; if the loan is not tainted with illegality or immorality, or made for a purpose contrary to public policy, the amount may be recovered by a common law action. Where an intending borrower breaks his agreement to borrow, specific performance will not be granted, and the damages recoverable must be measured by the loss sustained through the breach and not by the sum agreed to be lent (*The South African Territories, Limited* v. *Wallington* (1897), 1 Q.B. 692).

Authorities.—On equitable relief to borrowers reference should be made to Bellot and Willis's *Bargains with Money-lenders*. On the law under the act of 1900 see Hastings's *Law relating to Money-lenders and Unconscionable Bargains*; and Edmondson's *Money-lenders Act 1900.* For the taxation of the Jews in the middle ages, see Bridges, *The Jews of Europe in the Middle Ages*, and Gneist's *History of the English Constitution*. For American law relating to Usury, see Stimson's *American Statute Law*, and the statutes of the various states. For France and Germany, see the codes of those countries. (C. G. Ala.)

MONFORTE, or Monforte de Lemos, a town of north-western Spain, in the province of Lugo, on the Cabe, a small right-hand tributary of the Sil, and at the junction of the railways from Tuy and Astorga to Corunna. Pop. (1900), 12,912. Monforte is built on a hill surmounted by a ruined medieval citadel; it contains an ancient Benedictine monastery converted into a hospital, a Jesuit college, and a fine Renaissance parish church, besides several convents and palaces of the Leonese nobility. Monforte has manufactures of soap and linen, and some trade in timber and livestock.

MONGE, GASPARD (1746–1818), French mathematician, the inventor of descriptive geometry, was born at Beaune on the 10th of May 1746. He was educated first at the college of the Oratorians at Beaune, and then in their college at Lyons—where, at sixteen, the year after he had been learning physics, he was made a teacher of it. Returning to Beaune for a vacation, he made, on a large scale, a plan of the town, inventing the methods of observation and constructing the necessary instruments; the plan was presented to the town, and preserved in their library. An officer of engineers seeing it wrote to recommend Monge to the commandant of the military school at Mézières, and he was received as a draftsman and pupil in the practical school attached to that institution; the school itself was of too aristocratic a character to allow of his admission to it. His manual skill was duly appreciated: "I was a thousand times tempted," he said long afterwards, "to tear up my drawings in disgust at the esteem in which they were held, as if I had been good for nothing better." An opportunity, however, presented itself: being required to work out from data supplied to him the "défilement" of a proposed fortress (an operation then only performed by a long arithmetical process), Monge, substituting for this a geometrical method, obtained the result so quickly that the commandant at first refused to receive it—the time necessary for the work had not been taken; but upon examination the value of the discovery was recognized, and the method was adopted. And Monge, continuing his researches, arrived at that general method of the application of geometry to the arts of construction which is now called descriptive geometry (see Geometry, Descriptive). But such was the system in France before the Revolution that the officers instructed in the method were strictly forbidden to communicate it even to those engaged in other branches of the public service; and it was not until many years afterwards that an account of it was published.

In 1768 Monge became professor of mathematics, and in 1771 professor of physics, at Mézières; in 1778 he married Mme Horbon, a young widow whom he had previously defended in a very spirited manner from an unfounded charge; in 1780 he was appointed to a chair of hydraulics at the Lyceum in Paris (held by him together with his appointments at Mézières), and was received as a member of the *Académie*; his intimate friendship with C. L. Berthollet began at this time. In 1783, quitting Mézières, he was, on the death of É. Bézout, appointed examiner of naval candidates. Although pressed by the minister to prepare for them a complete course of mathematics, he declined to do so, on the ground that it would deprive Mme Bézout of her only income, from the sale of the works of her late husband; he wrote, however (1786), his *Traité élémentaire de la statique.*

Monge contributed (1770–1790) to the *Memoirs* of the Academy of Turin, the *Mémoires des savantes étrangers* of the Academy of Paris, the *Mémoires* of the same Academy, and the *Annales de chimie*, various mathematical and physical papers. Among these may be noticed the memoir "Sur la théorie des déblais et des remblais" (*Mém. de l'acad. de Paris*, 1781), which, while giving a remarkably elegant investigation in regard to the problem of earth-work referred to in the title, establishes in connexion with it his capital discovery of the curves of curvature of a surface. Léonhard Euler, in his paper on curvature in the Berlin *Memoirs* for 1760, had considered, not the normals of the surface, but the normals of the plane sections through a particular normal, so that the question of the intersection of successive normals of the surface had never presented itself to him. Monge's memoir just referred to gives the ordinary differential equation of the curves of curvature, and establishes the general theory in a very satisfactory manner; but the application to the interesting particular case of the ellipsoid was first made by him in a later paper in 1795. A memoir in the volume for 1783 relates to the production of water by the combustion of hydrogen; but Monge's results had been anticipated by Henry Cavendish.

In 1792, on the creation by the Legislative Assembly of an executive council, Monge accepted the office of minister of the marine, but retained it only until April 1793. When the Committee of Public Safety made an appeal to the savants to assist in producing the *matériel* required for the defence of the republic, he applied himself wholly to these operations, and distinguished himself by his indefatigable activity therein; he wrote at this time his *Description de l'art de fabriquer les canons*, and his *Avis aux ouvriers en fer sur la fabrication de l'acier.* He took a very active part in the measures for the establishment of the normal school (which existed only during the first four months of the year 1795), and of the school for public works, afterwards the polytechnic school, and was at each of them professor for descriptive geometry; his methods in that science were first published in the form in which the shorthand writers took down his lessons given at the normal school in 1795, and again in 1798–1799. In 1796 Monge was sent into Italy with C. L. Berthollet and some artists to receive the pictures and statues levied from several Italian towns, and made there the acquaintance of General Bonaparte. Two years afterwards he was sent to Rome on a political mission, which terminated in the establishment, under A. Masséna, of the short-lived Roman republic; and he thence joined the expedition to Egypt, taking part with his friend Berthollet as well in various operations of the war as in the scientific labours of the Egyptian Institute of Sciences and Arts; they accompanied Bonaparte to Syria, and returned with him in 1798 to France. Monge was appointed president of the Egyptian commission, and he resumed his connexion with the polytechnic school. His later mathematical papers are published (1794–1816) in the *Journal* and the *Correspondance* of the polytechnic school. On the formation of the Senate he was appointed a member of that body, with an ample provision and the title of count of Pelusium; but on the fall of Napoleon he was deprived of all his honours, and even excluded from the list of members of the reconstituted Institute. He died at Paris on the 28th of July 1818.

For further information see B. Brisson, *Notice historique sur Gaspard Monge*; Dupin, *Essai historique sur les services et les travaux scientifiques de Gaspard Monge* (Paris, 1819), which contains (pp. 162–166) a list of Monge's memoirs and works; and the biography by F. Arago (*Œuvres*, t. ii., 1854).

Monge's various mathematical papers are to a considerable extent reproduced in the *Application de l'analyse à la géométrie* (4th ed., last revised by the author, Paris, 1819); the pure text of this is reproduced in the 5th éd. (revue, corrigée et annotée par M. Liouville) (Paris, 1850), which contains also Gauss's Memoir, "Disquisitiones generales circa superficies curvas," and some valuable notes by the editor. The other principal separate works are *Traité élémentaire de la statique, 8e édition, conformée à la precédente, par M. Hachette, et suivie d'une note &c., par M. Cauchy* (Paris, 1846); and the *Géométrie descriptive* (originating, as mentioned above, in the lessons given at the normal school). The 4th edition, published shortly after the author's death, seems to have been substantially the same as the 7th (*Géométrie déscriptive par G. Monge, suivie d'une théorie des ombres et de la perspective, extraite des papiers de l'auteur, par M. Brisson* (Paris, 1847). (A. Ca.)

MONGHYR, a town and district of British India, in the Bhagalpur division of Bengal. The town is on the right bank of the Ganges, and has a railway station, with steam ferry to the railway on the opposite bank of the river. Pop. (1901), 35,880. In 1195 Monghyr, a fortress of great natural strength, appears to have been taken by Mahommed Bakhiyar Khilji, the first Moslem conqueror of Bengal. Henceforth it is often mentioned by the Mahommedan chroniclers as a place of military importance, and was frequently chosen as the seat of the local government. After 1590, when Akbar established his supremacy over the Afghan chiefs of Bengal, Monghyr was long the headquarters of his general, Todar Mal; and it also figures prominently during the rebellion of Sultan Shuja against his brother, Aurangzeb. In more recent times Nawab Mir Kasim, in his war with the English, selected it as his residence and the centre of his military preparations. Monghyr is famous for its manufactures of iron: firearms, swords, and iron articles of every kind are produced in abundance but are noted for cheapness rather than quality. The art of inlaying sword-hilts and other articles with gold and silver affords employment to a few families.

The District of Monghyr has an area of 3922 sq. m. The Ganges divides it into two portions. The northern, intersected by the Burhi Gandak and Tiljuga, two important tributaries of the Ganges, is always liable to inundation during the rainy season, and is a rich, flat, wheat and rice country, supporting a large population. A considerable area, immediately bordering the banks of the great rivers, is devoted to permanent pasture. Immense herds of buffaloes are sent every hot season to graze on these marshy prairies; and the *ghi*, or clarified butter, made from their milk forms an important article of export to Calcutta. To the south of the Ganges the country is dry, much less fertile, and broken up by fragmentary ridges. Irrigation is necessary throughout the section lying on the south of the Ganges. The population in 1901 was 2,068,804, showing an increase of 1·6% in the decade. The principal exports sent to Calcutta, both by rail and by river, are oil-seeds, wheat, rice, indigo, grain and pulse, hides and tobacco; and the chief imports consist of European piece-goods, salt and sugar. The southern portion of the district is well provided with railways. At Lakhisarai junction the arc and chord lines of the East Indian railway divide, and here also starts the branch to Gaya. At Jamalpur, which is the junction for Monghyr, are the engineering workshops of the company. In the early years of British rule Monghyr formed a part of Bhagalpur, and was not created a separate district till 1832.

See *Monghyr District Gazetteer* (Calcutta, 1909).

MŌNG NAI (called by the Burmese and on most old maps *Monē*), one of the largest and most important of the states in the eastern subdivision of the southern Shan States of Burma. The state of Kēng Tawng (Burmese Kyaing Taung) is a dependency of Mōng Nai. It lies approximately between 20° 10′ and 21° N. and between 97° 30′ and 98° 45′ E., and occupies an area of 2717 sq. m.; pop. (1901), 44,252, of whom more than five-sixths are Shans. The Salween river bounds it on the east. The main state and the sub-state of Kēng Tawng consist of two plains with a ridge between them. There is much flat rice bottom, but a considerable portion consists of gently undulating plainland. In the central plain rice is the only crop. Outside this considerable quantities of sugar are produced. Tobacco of a quality highly esteemed by the Shans is grown in the Nawng Wawp circle at an altitude of 3100 ft. above sea-level; gram, *thanatpet* (a leaf used for cigar-wrappers), and garden crops are the chief produce otherwise. In the outlying tracts quantities of coarse native paper are manufactured from the bark of a species of mulberry, and much is exported to other parts of the Shan States.

MONGOLIA, a vast territory belonging to the Chinese empire, the administrative limits of which cannot be determined with precision. On the N. it is bounded by the frontier of Russia, beginning at Mount Kalas or Kanas (49° 5′ N., 87° 40′ E.) in the Altai, and running to the S.E. corner of Transbaikalia in the vicinity of Dalai-nor, thus having on the N. the Siberian provinces of Tomsk, Yeniseisk, Irkutsk and Transbaikalia. In the E. the boundary line which separates Mongolia from Manchuria runs past Dalai-nor and Lake Buir, crossing the Great Khingan in 47° 30′ N., towards Tsitsihar in Manchuria; then, crossing the Nonni river, it strikes the Sungari at Khulanchen, where it turns westwards up this river, reaching the Shara-muren river in 123° 30′ E. From China proper on the S. Mongolia is separated by a line running in a south-westward direction up the Shara-muren and across the Mongolian plateau to the bending of the Hwang-ho or Yellow river in about 40° N. and 110° 30′ E. Thence the boundary describes a sinuous line, following the Great Wall, and thus includes the Ordos (Ho-tau) and Alashañ (Si-tao), and reaches its most southern point in 36° 40′ N., 104° 20′ E. Thence it turns north-west, following the Great Wall for over 300 m.; it then crosses the plateau so as to separate Mongolia from the Chinese province of Sin-Kiang (*Hañ-su-sin-tsiang*, which includes the Nan-shan highlands and eastern Turkestan), and from Dzungaria, reaching the Chinese or Ektagh Altai in 46° 30′ N., 92° 50′ E. From that point the boundary coincides with the main water-parting of the Altai Mountains till it reaches Mount Kalas.

Geographically, Mongolia may thus be said to occupy both terraces of the great plateau of east Asia, which stretches in the south of Siberia, between the Sailughem range of the Great Altai and the Great Khingan—with the exception of the Dzungarian depression. From Manchuria and China it is separated by the border ridge of the plateau—the Great Khingan, while in the south-west it runs up to the foot of the high northern border ridges of the Tibetan plateau—an artificial frontier separating it from east Turkestan and Dzungaria. Broadly speaking, Mongolia may be divided naturally into three parts: (1) north-western Mongolia, which occupies the high terrace of the plateau; (2) the Gobi, in its wide sense, covering the lower terrace of the plateau, together with a slightly more elevated and better-watered zone along the western slope of the Great Khingan and its south-western continuation; and (3) south-eastern Mongolia, on the eastern slope of the Khingan. Of these parts, the second is considered in detail under the heading GOBI.

North-western Mongolia.

North-western Mongolia was formerly represented as a region intersected by lofty mountain chains. It appears, however, from Russian explorations during the last third of the 19th century, that it has all the characteristics of an elevated plateau, of a rhomboid shape (like Bohemia), bounded by four mountain ranges; namely, the Russian Altai on the N.W., the Sayans on the N.E., the Kentei range on the S.E., and the Ektagh Altai on the S.W. The border-ridge character of the Sayans (Ergik-targak-taiga) is well established, and the same orographic character is confirmed by recent explorers with regard to the Sailughem range of the Altai. The only point still remaining undecided is whether the valleys of the Bom-kemchik (a tributary of the Yenisei) and its left-hand tributaries do not belong geographically to the Altai region. At any rate, throughout the whole of north-west Mongolia, which covers an area of nearly 370,000 sq. m., the altitude nowhere falls below 2370 ft. (Ubsa-nor), and the area round this lake which has less than 3000 ft. of altitude covers only 6600 sq. m. The remainder of this extensive territory ranges at altitudes of 3000 to 4500 ft., even in the bottoms of the river valleys and in the lower plains; while the ridges which constitute the water-partings rise about 2000 ft. above the general level of the plateau. Along the south-western border of this division of Mongolia a gigantic border-ridge, the Ektagh (or Mongolian) Altai, runs in an E.S.E. direction from the Russian Altai to 99° E. and is probably continued even farther by the Artsa-bogdo, the Saikhat and other ranges as far as the northern loop of the Yellow river. The passes across the Ektagh Altai lie at altitudes of 10,000 ft. in the north-west and 9250 ft. in 93° 20′ E.; farther east they become much lower. But while its southern foot stands in the Dzungarian trench, *i.e.* at altitudes of 1550 ft. only near Lake Ulungur, and at 3000 ft. in 94° E., its north-eastern foot rests on the high plateau, *i.e.* at 4260 ft. at Kobdo, 5410 at Oshku, 4070 at Orok-nor on the route from Kiakhta to Su-chow, and so on. Thus the Ektagh Altai is a true border-range—that is, a lofty and steep escarpment facing the Dzungarian depression, with a gentle and relatively short slope towards the plateau.

In the same way the Kentei (or Gentei) Mountains, as they are called, to the north of Urga, and the Yablonoi Mountains of Transbaikalia, separate the higher terrace of north-west Mongolia (drained by the tributaries of the Selenga) from the lower terrace of the Gobi, which is drained by the upper tributaries of the Onon and the Kerulen, both belonging to the basin of the Amur. It is also very probable that the Tannu-ola Mountains north-east of Ubsa-nor, and the Khangai Mountains between Ulyasutai and the upper Orkhon, both running W.N.W. to E.S.E., border another slightly higher terrace of the same great plateau of north-west Mongolia, upon which Lake Kossogol lies, at an altitude of 5320 ft. On this vast upper terrace even the bottoms of the river valleys are at altitudes of 4200 to 5500 ft., with one single exception—the narrow gorge of the Khua (Khi)-khem, or upper Yenisei; while the highest pass across the Tannu-ola Mountains is 7090 ft., though the others are much lower. The conception of north-west Mongolia as a region filled with mountain ranges radiating from the Altai must thus be abandoned. It is a massive swelling of the earth's crust, representing the northern counterpart of the plateau of Tibet. This massive swelling is cut into, between the Ektagh Altai and the eastern T'ien-shan, by the relative depression of Tarbagatai and Dzungaria, 1500 to 3000 ft. in altitude; while to the south of the eastern T'ien-shan comes the Tarim depression, from 2200 to 3000 ft. high, and occupying an area of about 88,000 sq. m. Neither of these "depressions," however, penetrates beyond 94° E., and on the route from Kiakhta to Su-chow, in 100° E., there is only one single place (42° N.) in which the altitude drops as low as 3300 ft.; everywhere else it varies between 4000 and 5000 ft.

Lakes and Rivers.—North-western Mongolia is well watered, and has in its western part a group of lakes which possess no outlet to the ocean, being in reality the rapidly desiccating remains of what were formerly much larger basins. The chief of them is Ubsa-nor (2370 ft.), which receives the large river Tes. It lies in the middle of a large plain, and has to the west of it a smaller but much higher lake, Urga-nor, besides several smaller ones. Farther south on the same wide plain lie the sister lakes Kirghiz-nor and Airyk-nor, which receive another large river, the Dzap'hyn, and the Kungui. Many small lakes are scattered over the plain to the east of them. A third group of lakes occur in the neighbourhood of Kobdo. The Kobdo river, which rises in the Dain-gol (7060 ft.) in the Ektagh Altai, winds in great curves across the plateau, and enters Lake Kara-usu (3840 ft.), which also receives the Buyantu, an outflow from Lake Kobdo, and is connected by a small river with another large lake, Durga-nor, situated a score of miles to the east. There are also many smaller lakes fed by the glaciers of the Sailughem (Achit-nor, 4650 ft., and Uryu-nor), and others scattered through the Ektagh Altai. The largest lake of this region is, however, Kosogol (Khubsu-gul), which lies at an altitude of 5320 ft., close to the Russian frontier, at the foot of the snow-clad Munku-sardyk. Besides the rivers just mentioned, there are others belonging to the basin of the Yenisei (Khua-or Khi-khem, Bei-khem and Bom-kemchik); while yet others belong to the Selenga, a river formed by the junction of the Eder with the Telghir. The Selenga receives the Orkhon, at the head of which remarkable inscriptions were discovered in the end of the 19th century, and cleverly deciphered by Professor V. Thomsen of Copenhagen.[1] The rivers which flow down the outer slopes of the border-ridges become lost in the Gobi shortly after entering it.

A very large portion of north-west Mongolia constitutes a high plain, 3000 to 4200 ft. in altitude, which penetrates from the south-east in a north-western direction between the Ektagh Altai and the Khangai Mountains. It has a true Mongolian character, *i.e.* it is covered with gravel, and presents the appearance of a dry prairie devoid of forests. This same character is also exhibited by the bottoms of the broad valleys, while the more elevated and hilly portions of the territory, especially on their northern slopes, are covered with larch, cedar, pine and deciduous trees belonging to the Siberian flora; where the forests fail they are marshy or assume the character of Alpine meadows—*e.g.* in the Khangai, the Tannu-ola, and on the slopes of the border-ridges. The whole of this region is covered with excellent pasture. The forests decrease as one travels southwards. For instance, while both slopes of the Sayans are covered with forests, the Tannu-ola and the Khangai Mountains have woods on their northern faces only, and the Ektagh Altai is quite devoid of woods, even on its northern slope.

Climate.—Owing to its high altitude, north-western Mongolia is very cold, and the severity of the winter is intensified by the prevalence of cold but dry north-western winds. The north-east wind brings more moisture. In summer the warm winds come from the south and south-east, but having first to cross the Gobi, they are dried before they reach north-western Mongolia. The yearly amount of rain at Urga (altitude 4350 ft., at the northern foot of the Kentei Mountains) is only 9½ in., and the average temperatures are: year 27° F., January −18°, July 64°; a minimum of −35° F. has been observed. The climate of Ulyasutai (5400 ft.) may be taken as typical, its average temperatures being: year 31·6°, January −12°, July 66°.

---

[1] See V. Thomsen, *Inscriptions de l'Orkhon* (Helsingfors, 1900)

The *geology* is still very imperfectly known. The plateau is built up of granites, gneisses and crystalline schists of Archean and probably Primary age. Coal is known to exist to the south-east of Kobdo, in the Tannu-ola, and in the basin of the Yenisei, but its age is unknown (fresh-water Jurassic ?). Graphite and some silver ores have also been found.

The *fauna* is a mixture of the Siberian and the Daurian—the latter penetrating up the valleys of the Selenga basin. The chief towns of north-west Mongolia are Urga, Ulyasutai, Kobdo and Ulankom.

South-eastern Mongolia.

South-eastern Mongolia is the part of Mongolia which lies on the eastern slope of the Great Khingan Mountains, entering like a wedge between the lower course of the Nonni river and the middle Sungari. Chiefly owing to the dryness of climate, its physical characteristics are similar to those of Mongolia proper, except that the altitude of the plains is much lower. This portion of Mongolia is also much better watered, namely, by the Khatsyr, the Lao-ho and the Shara-muren, all flowing from the Khingan Mountains eastwards, and the last making the frontier between Mongolia and the Chinese province of Chihli.

Population.—The population of the whole of Mongolia is estimated at about 5,000,000. It consists of Mongols—Eastern Mongols and Kalmucks in the west—various Turkish tribes, Chinese and Tunguses. The Mongols proper, with the exception of those who inhabit north-west Mongolia, may be divided into northern and southern (more properly north-western and south-eastern) Mongols. The former, belonging to the Khalkas, occupy the Gobi and the regions of the Kentei Mountains and Khingan Mountains, while the second, divided into numerous minor branches, roam over south-eastern and southern Mongolia. The principal occupation of the Mongols is cattle-breeding, and Russian writers estimate that on an average each *yurta*, or family, has about 50 sheep, 25 horses, 15 horned cattle and 10 camels. The transport of goods is their next most important occupation. It is calculated that 100,000 camels are used for the transport of tea only from Kalgan to Siberia, and that no less than 1,200,000 camels and 300,000 ox-carts are employed in the internal caravan trade. Agriculture is only carried on sporadically, chiefly in the south, where the Mongols have been taught by the Chinese. Various domestic industries are also carried on. The trade is chiefly concentrated at Urga, Ulyasutai and Kobdo in north-west Mongolia; Kalgan, Kuku-khoto, Kuku-erghi, Dolon-nur and Biru-khoto in southern and south-eastern Mongolia; and at Kerulen in the north-east.

Administration.—Before the Manchurian conquest the Mongols were governed by their own feudal princes, who regarded themselves as being descended from seven different ancestors, all, however of the same kin. Each group of principalities constituted a separate *aimak*, and each principality a separate *hoshun*. Under Manchu rule the *aimaks* became converted into the same number of military corps, each composed of so many *hoshuns* as military units. Each of these again was divided into *sumuns* or squadrons, each containing 150 families. In case a *hoshun* contained more than 6 *sumuns*, every 6 of the latter were organized into a regiment—*tsalan*. Four Manchu *tsian-tsuns*, or governor-generals, acted as chiefs of the troops, and the prince of each *aimak*, nominated from Peking, was considered as the lieutenant or assistant of his respective Manchu chief. The *hoshuns* were subject to their own princes, each of whom had a military adviser, generally a Manchu. Their internal or tribal affairs were in the hands of the princes, those which concerned a whole *aimak* being settled at gatherings of the princes under the eldest of them, named khan. This organization was maintained by the Manchu rulers, the khan being elected from among the princes, and the latter having each an adviser, *tusalakchi*, nominated from Peking.

Mongolia is now administered by a *Lifan Yuen* or superintendency with headquarters at Peking. Excluding the territory to which the name of Mongolia is geographically applied, but which is included in the provinces of Shansi and Chihli, Mongolia is divided into inner and outer divisions. Inner Mongolia, lying between the desert of Gobi, China proper and Manchuria, is divided into 24 *aimaks*. There are two military governors-general and two commissaries of the viceroy of Chihli, having control of civil matters. One of each pair of officials is stationed at Kalgan, and the other at Jehol. Outer Mongolia, the remainder of the territory, has 4 *aimaks*, three of which are under hereditary *khans*. There is a Chinese imperial agent at Urga.

Authorities.—The following works in Russian are the most important: Prjevalsky, *Mongolia and the Land of the Tanguts* (1875), and his *Third and Fourth Journey* (1883 and 1888); G. N. Potanin, *Sketches of North-West Mongolia* (1881–1883); *The Tangut-Tibet Border of China and Central Mongolia* (1893 seq.); V. Pyevtsoff, *Sketch of a Journey to Mongolia, &c.* (Omsk, 1883); D. Pozdnéeff, *Towns of North Mongolia* (1880); *Mongolia and the Mongols* (1896 and 1899); and the article "Mongolia" in *Russian Encycl. Dictionary*, vol. xix. (1896); G. and M. Grum Grzimailo, *Description of a Journey to Western China* (1898–1899); V. Pyevtsoff, K. Bogdanovitch, V. I. Roborovsky and P. K. Kozloff, *The Tibet Expeditions* (1886–1902); V. Obrucheff, *Central Asia, Northern China and the Nan-shan* (1900–1901); Z. Matusovskiy, *Geogr. Descr. of Chinese Empire* (1888); Batorskiy, *Essay of a Military and Statistic Sketch* (1890); A. Woyeikoff, *Climates of the Earth* (1884); *Mongolia and Kham* (Imperial Russian Geographical Society's Expedition, 1899–1901). See also R. Pumpelly, *Geol. Researches* (Washington, 1866); Ney Elias, in *Journal R.G.S.* (1873); Baron Richthofen, *China* (1877); J. Gilmour, *Among the Mongols* (1883); W. W. Rockhill, *Journey through Mongolia and Thibet* (1894); F. E. Younghusband, *The Heart of a Continent* (1896). (P. A. K.)

MONGOLS, the name of one of the chief ethnographical divisions of the Asiatic peoples (see also Turks). The early history of the Mongols, like that of all central-Asian tribes, is extremely obscure. Even the meaning of the name "Mongol" is a disputed point, though a general consent is now given to Schott's etymology of the word from *mong*, meaning brave. From the earliest and very scanty notice we have of the Mongols in the history of the T'ang dynasty of China (A.D. 619–690) and in works of later times, it appears that their original camping-grounds were along the courses of the Kerulen, Upper Nonni and Argun rivers. But in the absence of all historical particulars of their origin, legend, as is usual, has been busy with their early years. The Mongol historian Sanang Setzen gives currency to the myth that they sprang from a blue wolf; and the soberest story on record is that their ancestor Budantsar was miraculously conceived of a Mongol widow. By craft and violence Budantsar gained the chieftainship over a tribe living in the neighbourhood of his mother's tent, and thus left a heritage to his son. Varying fortunes attended the descendants of Budantsar, but on the whole their power gradually increased, until Yesukai, the father of Jenghiz Khan, who was eighth in descent from Budantsar, made his authority felt over a considerable area. How this dominion was extended under the rule of Jenghiz Khan is shown in the article Jenghiz Khan, and when that great conqueror was laid to rest in the valley of Kilien in 1227 he left to his sons an empire which stretched from the China Sea to the banks of the Dnieper.

Ogdai Khan.

Over the whole of this vast region Jenghiz Khan set his second surviving son Ogotai or Ogdai as khakan, or chief khan, while to the family of his deceased eldest son Juji he assigned the country from Kayalik and Khwarizm to the borders of Bulgar and Saksin "where'er the hoofs of Mongol horse had tramped"; to Jagatai, his eldest surviving son, the territory from the borders of the Uighur country to Bokhara; while Tulé, the youngest, received charge of the home country of the Mongols, the care of the imperial encampment and family, and of the archives of the state. The appointment of Ogdai as his successor being contrary to the usual Mongol custom of primogeniture, gave rise to some bitterness of feeling among the followers of Jagatai. But the commands of Jenghiz Khan subdued these murmurs, and Ogdai was finally led to the throne by his dispossessed brother amid the plaudits of the assembled Mongols. In accordance with Mongol customs, Ogdai signalized his accession to the throne by distributing among his grandees presents from his father's treasures, and to his father's spirit he sacrificed forty maidens and numerous horses. Once fairly on the throne, he set himself vigorously to follow up the conquests won by his father. At the head of a large army he marched southwards into China to complete the ruin of the Kin dynasty, which had already been so rudely shaken, while at the same time Tulē advanced into the province of Honan from the side of Shensi. Against this combined attack the Kin troops made a vigorous stand, but the skill and courage of the Mongols bore down every opposition, and over a hecatomb of slaughtered foes they captured Kai-fēng Fu, the capital of their enemies. From Kai-fēng Fu the emperor fled to Ju-ning Fu, whither the Mongols quickly followed. After sustaining a siege for some weeks, and enduring all the horrors of starvation, the garrison submitted to the Mongols, and at the same time the emperor committed suicide by hanging. Thus fell in 1234 the Kin or "Golden" dynasty, which had ruled over the northern portion of China for more than a century.

But though Ogdai's first care was to extend his empire in the rich and fertile provinces of China, he was not forgetful of the obligation under which Jenghiz Khan's conquests in western Asia had laid him to maintain his supremacy over the kingdom of Khwarizm. This was the more incumbent on him since Jelāl ed-dīn, who had been driven by Jenghiz into India, had returned, reinforced by the support of the sultan of Delhi, whose daughter he had married, and, having reconquered his hereditary domains, had advanced westward as far as Tiflis and Kelat. Once more to dispossess the young sultan, Ogdai sent a force of 300,000 men into Khwarizm. With such amazing rapidity did this army march in pursuit of its foe that the advanced Mongol guards reached Amid (Diarbekr), whither Jelāl ed-dīn had retreated, before that unfortunate sovereign had any idea of their approach. Accompanied by a few followers, Jelāl ed-dīn fled to the Kurdish Mountains, where he was basely murdered by a peasant. The primary object of the Mongol invasion was thus accomplished; but, with the instinct of their race, they made this conquest but a stepping-stone to another, and without a moment's delay pushed on still farther westward. Unchecked and almost unopposed, they overran the districts of Diarbekr, Mesopotamia, Erbīl and Kelat, and then advanced upon Azerbāijān. In the following year (1236) they invaded Georgia and Great Armenia, committing frightful atrocities. Tiflis was among the cities captured by assault, and Kars was surrendered at their approach in the vain hope that submission would gain clemency from the victors. Meanwhile, in 1235, Ogdai despatched three armies in as many directions. One was directed against Korea, one against the Sung dynasty, which ruled over the provinces of China south of the Yangtsze Kiang, and the third was sent westward into eastern Europe. This last force was commanded by Batu, the son of Juji, Ogdai's deceased eldest brother, who took with him the celebrated Sabutai Bahādur as his chief adviser. Bolgari, the capital city of the Bulgars, fell before the force under Sabutai, while Batu pushed on over the Volga. With irresistible vigour and astonishing speed the Mongols made their way through the forests of Penza and Tambov, and appeared before the "beautiful city" of Ryazan. For five days they discharged a ceaseless storm of shot from their balistas, and, having made a breach in the defences, carried the city by assault on the 21st of December 1237. "The prince, with his mother, wife, sons, the boyars and the inhabitants, without regard to age or sex, were slaughtered with the savage cruelty of Mongol revenge; some were impaled, some shot at with arrows for sport, others were flayed or had nails or splinters of wood driven under their nails. Priests were roasted alive, and nuns and maidens ravished in the churches before their relatives. 'No eye remained open to weep for the dead.'" Moscow, at this time a place of little importance, next fell into the hands of the invaders, who then advanced against Vladimir. After having held out for several days against the Mongol attacks, the city at length succumbed, and the horrors of Ryazan were repeated. If possible, a more dire fate overtook the inhabitants of Kozelsk, near Kaluga, where, in revenge for a partial defeat inflicted on a Mongol force, the followers of Batu held so terrible a "carnival of death" that the city was renamed by its captors Mobalig, "the city of woe." With the tide of victory thus strong in their favour the Mongols advanced against Kiev, "the mother of cities," and carried it by assault. The inevitable massacre followed, and the city was razed to the ground.

Victorious and always advancing, the Mongols, having desolated this portion of Russia, moved on in two divisions, one under Batu into Hungary, and the other under Baidar and Kaidu into Poland. Without a check, Batu marched to the neighbourhood of Pest, where the whole force of the kingdom was arrayed to resist him. The Hungarian army was posted on the wide heath of Mohi, which is bounded by "the vine-clad hills of Tokay," the mountains of Lomnitz, and the woods of Diosgyor. To an army thus hemmed in on all sides defeat meant ruin, and Batu instantly recognized the dangerous position in which his enemies had placed themselves. To add to his chances of success he determined to deliver his attack by night, and while the careless Hungarians were sleeping he launched his battalions into their midst. Panic-stricken and helpless, they fled in all directions, followed by their merciless foes. Two archbishops, three bishops, and many of the nobility were among the slain, and the roads for two days' journey from the field of battle were strewn with corpses. The king, Bēla IV., was saved by the fleetness of his horse, though closely pursued by a body of Mongols, who followed at his heels as far as the coast of the Adriatic, burning and destroying everything in their way. Meanwhile Batu captured Pest, and on Christmas Day 1241, having crossed the Danube on the ice, took Esztergom by assault. While Batu had been thus triumphing, the force under Baidar and Kaidu had carried fire and sword into Poland. While laying waste the country they received the announcement of the death of Ogdai, and at the same time a summons for Batu to return eastwards into Mongolia.

While his lieutenants had been thus carrying his arms in all directions, Ogdai had been giving himself up to ignoble ease and licentiousness. Like many Mongols, he was much given to drink, and it was to a disease produced by this cause that he finally succumbed on the 11th of December 1241. He was succeeded by his son Kuyuk, who reigned only seven years. Little of his character is known, but it is noticeable that his two ministers to whom he left the entire conduct of affairs were Christians, as also were his doctors, and that a Christian chapel stood before his tent. This leaning towards Christianity, however, brought no peaceful tendencies with it. On the death of Kuyuk dissensions which had been for a long time smouldering between the houses of Ogdai and Jagatai broke out into open war, and after the short and disputed reigns of Kaidu and Chapai, grandsons of Ogdai, the lordship passed away for ever from the house of Ogdai. It did not go, however, to the house of Jagatai, but to that of Tulē.

Mangu Khan.

On the 1st of July 1251 Mangu, the eldest son of Tulē, and nephew to Ogdai, was elected khakan. With perfect impartiality, Mangu allowed the light of his countenance to fall upon the Christians, Mahommedans and Buddhists among his subjects although Shamanism was recognized as the state religion. Two years after his accession his court was visited by Rubruquis (*q.v.*) and other Christian monks, who were hospitably received. The description given by Rubruquis of the khakan's palace at Karakorum shows how wide was the interval which separated him from the nomad, tent-living life of his forefathers. It was "surrounded by brick walls. . . . Its southern side had three doors. Its central hall was like a church, and consisted of a nave and two aisles, separated by columns. Here the court sat on great occasions. In front of the throne was placed a silver tree, having at its base four lions, from whose mouths there spouted into four silver basins wine, kumiss, hydromel and terasine. At the top of the tree a silver angel sounded a trumpet when the reservoirs that supplied the four fountains wanted replenishing." On his accession complaints reached Mangu that dissensions had broken out in the province of Persia, and he therefore sent a force under the command of his brother Hulagu to punish the Ismailites or Assassins (*q.v.*), who were held to be the cause of the disorder. Marching

Hulagu.

by Samarkand and Karshi, Hulagu crossed the Oxus and advanced by way of Balkh into the province of Kuhistan or Kohistan. The terror of the Mongol name induced Rukneddin Gurshah II. (Rokn al-din), the chief of the Assassins, to deprecate the wrath of Hulagu by offers of submission, and he was so far successful that he was able to purchase a temporary immunity from massacre by dismantling fifty of the principal fortresses in Kohistan. But when once the country had thus been left at the mercy of the invaders, their belief in the old saying "Stone dead hath no fellow" sharpened their battle-axes, and, sparing neither man, woman, nor child, they exterminated the unhappy people. Rukneddin having been killed, 1256 (see ASSASSINS), Hulagu marched across the snowy mountains in the direction of Bagdad to attack the last Abbasid caliph and his Seljuk protectors. On arriving before the town he demanded its surrender. This being refused, he laid siege to the walls in the usual destructive Mongol fashion, and at length, finding resistance hopeless, the caliph was induced to give himself up and to open the gates to his enemies. On the 15th of February 1258 the Mongols entered the walls and sacked the city (see CALIPHATE *ad fin*). While at Bagdad Hulagu gave his astronomer, Nāsir al-dīn permission to build an observatory. The town of Maragha was the site chosen, and, under the superintendence of Nāsir al-dīn and four western Asiatic astronomers who were associated with him, a handsome observatory was built, and furnished with "armillary spheres and astrolabes, and with a beautifully-executed terrestrial globe showing the five climates." The fall of Bagdad was almost contemporaneous with the end of the Seljuks of Konia as an independent power, though their actual destruction did not take place until 1308 (see SELJUKS). One terrible result of the Mongol invasion was a fearful famine, which desolated the provinces of Irak-Arabi, Mesopotamia, Syria and Rūm. But, though the inhabitants starved, the Mongols had strength and energy left to continue their onward march into Syria. Aleppo was stormed and sacked, Damascus surrendered (1260) and Hulagu was meditating the capture of Jerusalem with the object of restoring it to the Christians when he received the news of Mangu's death, and, as in duty bound, at once set out on his return to Mongolia, leaving Kitboga (Kitubuka) in command of the Mongol forces in Syria.

Hitherto a vassal of Mangu, as is shown by his striking coins bearing the name of Mangu as well as his own, Hulagu was now recognized as ruler of the conquered provinces. He assumed the title of ilkhan, and, although acknowledging the khakan as supreme lord, was practically independent. The title of ilkhan was that borne by his successors, who ruled over Persia for about a century (see *infra*, "The Ilkhans of Persia").

While Hulagu was prosecuting these conquests in western Asia, Mangu and his next brother Kublai were pursuing a like course in southern China. Southward they even advanced into Tong-king, and westward they carried their arms over the frontier into Tibet. But in one respect there was a vast difference between the two campaigns. Under the wise command of Kublai all indiscriminate massacres were forbidden, and probably for the first time in Mongol history the inhabitants and garrisons of captured cities were treated with humanity. While carrying on the war in the province of Szech'uen Mangu was seized with an attack of dysentery, which proved fatal after a few days' illness. His body was carried into Mongolia on the backs of two asses, and, in pursuance of the custom of slaughtering every one encountered on the way, 20,000 persons were, according to Marco Polo, put to the sword.

At the Kuriltai, or assembly of notables, which was held at Shang-tu after the death of Mangu, his brother Kublai (see KUBLAI KHAN) was elected khakan. For thirty-five years he sat on the Mongol throne, and at his death in 1294, in his seventy-ninth year, he was succeeded by his son Timur Khan, or, as he was otherwise called, Oldjeitu or Uldsheitu Khan (Chinese Yuen-chĕng). The reign of this sovereign was chiefly remarkable for the healing of the division which had for thirty years separated the families of Ogdai and Jagatai from that of the ruling khakan. Uldsheitu was succeeded by his nephew Khaissan, who was gathered to his fathers in February 1311, after a short reign, and at the early age of thirty-one. His nephew and successor, Buyantu (Chinese Yen-tsung), was a man of considerable culture, and substantially patronized Chinese literature. Among other benefits which he conferred on letters, he rescued the celebrated inscription-bearing "stone drums," which are commonly said to be of the Chow period (1122–255 B.C.), from the decay and ruin to which they were left by the last emperor of the Kin dynasty, and placed them in the gateway of the temple of Confucius at Peking, where they now stand. After a reign of nine years, Buyantu was succeeded by his son Gegen (Chinese Ying-tsung), who perished in 1323 by the knife of an assassin. Yissun Timur (Chinese Tai-ting-ti), who was the next sovereign, devoted himself mainly to the administration of his empire. He divided China, which until that time had been apportioned into twelve provinces, into eighteen provinces, and rearranged the system of state granaries, which had fallen into disorder. His court was visited by Friar Odoric, who gives a minute description of the palace and its inhabitants. Speaking of the palace this writer says:—

> "Its basement was raised about two paces from the ground, and within there were twenty-four columns of gold, and all the walls were hung with skins of red leather, said to be the finest in the world. In the midst of the palace was a great jar more than two paces in height, made of a certain precious stone called merdacas (jade); its price exceeded the value of four large towns. . . . Into this vessel drink was conducted by certain conduits from the court of the palace, and beside it were many golden goblets, from which those drank who listed. . . . When the khakan sat on his throne the queen was on his left hand, and a step lower two others of his women, while at the bottom of the steps stood the other ladies of his family. All those who were married wore upon their heads the foot of a man as it were a cubit and a half in length, and at the top of the foot there were certain cranes' feathers, the whole foot being set with great pearls, so that if there were in the whole world any fine and large pearls they were to be found in the decoration of those ladies."

The following years were years of great natural and political convulsions. Devastating floods swept over China, carrying death and ruin to thousands of homes; earthquakes made desolate whole districts; and in more than one part of the empire the banners of revolt were unfurled. Under various leaders the rebels captured a number of cities in the provinces of Kiang-nan and Honan, and took possession of Hang-chow, the capital of the Sung emperors. At the same time pirates ravaged the coasts and swept the imperial vessels off the sea.

In 1355 a Buddhist priest named Chu Yuen-chang became so impressed with the misery of his countrymen that he threw off his vestments and enrolled himself in the rebel army. His military genius soon raised him to the position of a leader, and with extraordinary success he overcame with his rude levies the trained legions of the Mongol emperor. While unable to defeat or check the rebels in the central provinces, Toghon Timur Khan was also called upon to face a rebellion in Korea. Nor were his arms more fortunate in the north than in the south. An army which was sent to suppress the revolt was cut to pieces almost to a man. These events made a dream which the emperor dreamt about this time of easy interpretation. He saw in his sleep "a wild boar with iron tusks rush into the city and wound the people, who were driven hither and thither without finding shelter. Meanwhile the sun and the moon rushed together and perished." "This dream," said the diviner, "is a prophecy that the khakan will lose his empire." The fulfilment followed closely on the prophecy. By a subterfuge the rebels, after having gained possession of most of the central provinces of the empire, captured Peking. But Toghon Timur by a hasty flight escaped from his enemies, and sought safety on the shores of the Dolon-nor in Mongolia. For a time the western provinces of China continued to hold out against the rebels, but with the flight of Toghon Timur the Mongol troops lost heart, and in 1368 the ex-Buddhist priest ascended the throne as the first sovereign of the Ming or "Bright" dynasty, under the title of Hung-wu.

Thus ended the sovereignty of the house of Jenghiz Khan in China, nor need we look far to find the cause of its fall. Brave

The Mongols expelled from China.

and hardy the Mongols have always shown themselves to be; but the capacity for consolidating the fruits of victory, for establishing a settled form of government, and for gaining the allegiance of the conquered peoples, have invariably been wanting in them.

Not content with having recovered China, the emperor Hungwu sent an army of 400,000 men into Mongolia in pursuit of the forces which yet remained to the khakan. Even on their own ground the disheartened Mongols failed in their resistance to the Chinese, and at all points suffered disaster. Meanwhile Toghon Timur, who did not long survive his defeat, was succeeded in the khakanate by Biliktu Khan, who again in 1379 was followed by Ussakhal Khan. During the reign of this last prince the Chinese again invaded Mongolia, and inflicted a crushing defeat on the khan's forces in the neighbourhood of Lake Buyur. Besides the slain, 2994 officers and 77,000 soldiers are said to have been taken prisoners, and an immense booty to have been secured. This defeat was the final ruin of the eastern branch of the Mongols, who from this time surrendered the supremacy to the western division of the tribe. At first the Keraits or Torgod, as in the early days before Jenghiz Khan rose to power, exercised lordship over the eastern Mongols, but from these before long the supremacy passed to the Oirad, who for fifty years treated them as vassals. Notwithstanding their subjection, however, the Keraits still preserved the imperial line, and khakan after khakan assumed the nominal sovereignty of the tribe, while the real power rested with the descendants of Toghon, the Oirad chief, who had originally attached them to his sceptre. Gradually, however, the Mongol tribes broke away from all governing centres, and established scattered communities with as many chiefs over the whole of eastern Mongolia. The discredit of having finally disintegrated the tribe is generally attached to Lingdan Khan (1604–1634), of whom, in reference to his arrogant and brutal character, has been quoted the Mongolian proverb: "A raging khakan disturbs the state, and a raging saghan (elephant) overthrows his keepers."

The Chakhars.

At this time the Mongols, though scattered and in isolated bodies, had recovered somewhat from the shock of the disaster which they had suffered at the hand of the first Ming sovereign of China. When first driven northwards, they betook themselves to the banks of the Kerulen, from whence they had originally started on their victorious career; but gradually, as the Chinese power became weaker among the frontier tribes, they again pushed southwards, and at this time had established colonies in the Ordus country, within the northern bend of the Yellow River. The Mongol royal family and their immediate surroundings occupied the Chakhar country to the north-west of the Ordus territory, where they became eventually subjugated by the Manchus on the overthrow of the Ming dynasty in 1644 by the present rulers of China. At times the old vigour and strength which had nerved the arm of Jenghiz Khan seemed to return to the tribe, and we read of successful expeditions being made by the Ordu Mongols into Tibet, and even of invasions into China. The relations with Tibet thus inaugurated brought about a rapid spread of Buddhism among the Mongolians, and in the beginning of the 17th century the honour of having a Dalai Lama born among them was vouchsafed to them. In 1625 Toba, one of the sons of Bushuktu Jinung Khan, went on a pilgrimage to the Dalai Lama, and brought back with him a copy of the Tanjur to be translated into Mongolian, as the Kanjur had already been. But though the prowess of the Ordu Mongols was still unsubdued, their mode of living was as barren and rugged as the steppes and rocky hills which make up their territory. Their flocks and herds, on which they are entirely dependent for food and clothing, are not numerous, and, like their masters, are neither well fed nor well favoured. But though living in this miserable condition their princes yet keep up a certain amount of barbaric state, and the people have at least the reputation of being honest.

Several of the tribes who had originally migrated with those who finally settled in the Ordu territory, finding the country to be so inhospitable, moved farther eastward into richer pastures. Among these were the Tumeds, one of whose chiefs, Altan Khan (Chinese Yen-ta), is famous in later Mongol history for the power he acquired. For many years during the 16th century he carried on a not altogether unsuccessful war with China, and finally, when peace was made (1571), the Chinese were fain to create him a prince of the empire and to confer a golden seal of authority upon him. In Tibet his arms were as successful as in China; but, as has often happened in history, the physical conquerors became the mental subjects of the conquered. Lamaism has always had a great attraction in the eyes of the Mongols, and, through the instrumentality of some Lamaist prisoners whom Altan brought back in his train, the religion spread at this time rapidly among the Tumeds. Altan himself embraced the faith, and received at his court the Bogda Sodnam Gyamtso Khutuktu, on whom he lavished every token of honour. One immediate effect of the introduction of Buddhism among the Tumeds was to put an end to the sacrifices which were commonly made at the grave of their chieftains. In 1584 Altan died, and was succeeded by his son Senge Dugureng Timur. The rich territory occupied by the Tumeds, together with the increased intercourse with China which sprang up after the wars of Altan, began to effect a change in the manner of life of the people. By degrees the pastoral habits of the inhabitants became more agricultural, and at the present day, as in Manchuria, Chinese immigrants have so stamped their mark on the fields and markets, on the towns and villages, that the country has become to all intents and purposes part of China proper.

The Kalkas.

Passing now from the inner division of the Mongols who live in the southern and eastern portions of the desert we come to the outer division, which occupies the territory to the north of the desert. Of these the chief are the Kalkas, who are divided into the Western and Eastern Kalkas. These people form the link of communication between Europe and eastern Asia. Early in the 17th century the Russians sent an embassy to the court of the Golden Khan with the object of persuading the Mongol khan to acknowledge allegiance to the tsar. This he did without much hesitation or inquiry, and he further despatched envoys to Moscow on the return of the Russian embassy. But the allegiance thus lightly acknowledged was lightly thrown off, and in a quarrel which broke out between the Khirghiz and the Russians the Kalkas took the side of the former. The breach, however, was soon healed over, and we find the Golden Khan sending an envoy again to Moscow, asking on behalf of his master for presents of jewels, arms, a telescope, a clock, and "a monk who had been to Jerusalem that he might teach the Kalkas how the Christians prayed." Their submission to Russia on the north did not save them, however, from the Chinese attacks on the south. At that time the present Manchu dynasty ruled in China, and to the then reigning sovereign the Kalkas gave in their submission. For some time the Chinese yoke sat lightly on their consciences, but difficulties having arisen with the Kalmucks, they were ready enough to claim the protection of China. To cement the alliance the emperor K'ang-hi invited all the Kalka chiefs to meet him at the plain of Dolon-nor. This ceremony brought the separate history of the Kalkas to a close, since from that time they have been engulfed in the Chinese Empire.

During the Kin dynasty of China the Keraits, as has been pointed out, were for a time supreme in Mongolia, and it was during that period that one of the earliest recognized sovereigns, Merghus Buyuruk Khan, sat on the throne. In an engagement with a neighbouring Tatar tribe their khan was captured and sent as a propitiatory present to the Kin emperor, who put him to death by nailing him on a wooden ass. On the treacherous Tatar chief the widow determined to avenge herself, and chose the occasion of a feast as a fitting opportunity. With well-disguised friendship she sent him a present of ten oxen, a hundred sheep and a hundred sacks of koumiss. These, last, however, instead of being filled with skins of the liquor which Mongolians love so well, contained armed men, who, when the Tatar was feasted, rushed from their concealment and killed him.

The Torgod.

A grandson of Merghus was the celebrated Wang Khan, who was sometimes the ally and sometimes the enemy of Jenghiz Khan, and has also been identified as the Prester John of early western writers. In war he was almost invariably unfortunate, and it was with no great difficulty, therefore, that his brother Ki Wang detached the greater part of the Kerait tribes from his banner, and founded the Torgod chieftainship, named probably from the country where they settled themselves. The unrest peculiar to the dwellers in the Mongolian desert disturbed the Torgod as much as their neighbours. Their history for several centuries consists of nothing but a succession of wars with the tribes on either side of them, and it was not until 1672, when Ayuka Khan opened relations with the Russians, that the country obtained an even temporarily settled existence. Its position, indeed, at this time made it necessary that Ayuka should ally himself either with the Russians or with his southern neighbours the Turks, though at the same time it was obvious that his alliance with the one would bring him into collision with the other. His northern neighbours, the Cossacks of the Yaik and the Bashkirs, both subject to Russia, had the not uncommon propensity for invading his borders and harassing his subjects. This gave rise to complaints of the tsar's government and a disposition to open friendly relations with the Krim khan. A rupture with Russia followed, and Ayuka carried his arms as far as Kazan, burning and laying waste the villages and towns on his route and carrying off prisoners and spoils. Satisfied with this vengeance, he advanced no farther, but made a peace with the Russians, which was confirmed in 1722 at an audience which Peter the Great gave him at Astrakhan. On Ayuka's death shortly after this event, he was succeeded by his son Cheren Donduk, who received from the Dalai Lama a patent to the throne. But this spiritual support availed him little against the plots of his nephew Donduk Ombo, who so completely gained the suffrages of the people that Cheren Donduk fled before him to St Petersburg, where he died, leaving his nephew in possession. With consummate impartiality the Russians, when they found that Donduk Ombo had not only seized the throne but was governing the country with vigour and wisdom, formally invested him with the khanate. At his death he was succeeded by Donduk Taishi, who, we are told, went to Moscow to attend the coronation of the empress Elizabeth, and to swear fealty to the Russians. After a short reign he died, and his throne was occupied by his son Ubasha. The position of the Torgod at this time, hemmed in as they were between the Russians and Turks, was rapidly becoming unbearable, and the question of migrating "bag and baggage" was very generally mooted. In the war between his two powerful neighbours in 1769 and 1770, Ubasha gave valuable assistance to the Russians. His troops took part in the siege of Ochakov, and gained a decided victory on the river Kalaus. Flushed with these successes, he was in no mood to listen patiently to the taunts of the governor of Astrakhan, who likened him to a "bear fastened to a chain," and he made up his mind to break away once and for all from a tutelage which was as galling as it was oppressive. He determined, therefore, to migrate eastward with his people, and on the 5th of January 1771 he began his march with 70,000 families. In vain the Russians attempted to recall the fugitives, who, in spite of infinite hardships, after a journey of eight months reached the province of Ili, where they were welcomed by the Chinese authorities. Food for a year's consumption was supplied to each family; and land, money and cattle were freely distributed. It is believed that 300,000 persons survived to receive the hospitality of the Chinese. By this desperate venture the Torgod escaped, it is true, the oppression of the Russians, but they fell into the hands of other masters, who, if not so exacting, were equally determined to be supreme. The Chinese, flattered by the compliment implied by the transference of allegiance, settled them on lands in the province of Ili, in the neighbourhood of the Altai mountains, and to the west of the desert of Gobi. But the price they were made to pay for this liberality was absorption in the Chinese empire.

The Kalmuck.

Galdan Khan.

Among the Mongol chiefs who rose to fame during the rule of the Ming dynasty of China was Toghon, the Kalmuck khan, who, taking advantage of the state of confusion which reigned among the tribes of Mongolia, established for himself an empire in north-western Asia. Death carried him off in 1444, and his throne devolved upon his son Ye-seen, who was no degenerate offspring. Being without individual foes in Mongolia he turned his arms against China, which through all history has been the happy hunting-ground of the northern tribes, and had the unexampled good fortune to take prisoner the Chinese emperor Chēng-t'ung. But victory did not always decide in his favour, and after having suffered reverses at the hands of the Chinese, he deemed it wise to open negotiations for the restoration of his imperial prisoner. Thus, after a captivity of seven years Chēng-t'ung re-entered his capital in 1457, not altogether to the general satisfaction of his subjects. On the death of Yi-sien, shortly after this event, the Kalmucks lost much of their power in eastern Asia, but retained enough in other portions of their territory to annoy the Russians by raids within the Russian frontier, and by constant acts of pillage. In the 17th century their authority was partly restored by Galdan, a Lama, who succeeded by the usual combination of wile and violence to the throne of his brother Senghē. Having been partly educated at Lhasa, he was well versed in Asiatic politics, and, taking advantage of a quarrel between the Black and White Mountaineers of Kashgar he overran Little Bokhara, and left a viceroy to rule over the province with his capital at Yarkand. At the same time he opened relations with China, and exchanged presents with the emperor. Having thus secured his powerful southern neighbour, as he thought, he turned his arms against the Kalkas, whose chief ground of offence was their attachment to the cause of his brothers. But his restless ambition created alarm at Peking, and the emperor K'ang-hi determined to protect the Kalkas against their enemy. The emperor, in person commanding one of the two forces, marched into Mongolia. After enduring incredible hardships during the march through the desert of Gobi the imperial army encountered the Kalmucks at Chao-modo. The engagement was fiercely contested, but ended in the complete victory of the Chinese, who pursued the Kalmucks for ten miles, and completely dispersed their forces. Galdan, with his son, daughter and a few followers, fled westward and escaped; and thus collapsed a power which had threatened at one time to overshadow the whole of Central Asia. For a time Galdan still maintained resistance to his powerful enemy, but death overtook him while yet in the field against the Chinese.

But though Galdan was dead the Chinese did not enjoy that complete immunity from war at the hand of his successor that they had looked for. Tsi-wang Arabtan was, however, but the shadow of his brother and predecessor, and a dispute which arose with the Russians during his reign weakened his power in other directions. Little Bokhara was said to be rich in gold mines, and therefore became a coveted region in the eyes of the Russians. Under the vigorous administration of Peter the Great an expedition was despatched to force a passage into the desired province. To oppose this invasion the Kalmucks assembled in force, and after a protracted and undecided engagement the Russians were glad to agree to retire down the Irtish and to give up all further advance.

To Tsi-wang Arabtan succeeded Amursama owing to the support he received from the Chinese emperor K'ien-lung, who nominated him khan of the Kalmucks and chief of Dzungaria. But, though to the ear these titles were as high-sounding as those of his predecessors, in reality the power they represented was curtailed by the presence of Chinese commissioners, in whose hands rested the real authority. The galling weight of this state of dependence drove Amursama before long into revolt. He dispersed the Chinese garrisons stationed in Ili (Kulja), killed the generals, and advanced his own forces as far as Palikun on the river Ili. To punish this revolt, K'ien-lung sent a large force into the rebellious province. As on the previous occasion, the

Chinese were everywhere victorious, and Amursama fled into Siberia, where he died of small-pox after a short illness.

While China was thus absorbing the Mongols within her reach, Russia was gathering within her borders those with whom she came into contact. Among these were the Buriats, who occupied a large territory on both sides of Lake Baikal. As usual in such cases, disputes arose out of disturbances on the frontier, and were ended by the Buriats and the neighbouring Mongol tribes becoming one and all tributary to Russia.

The House of Jagatai.

The dominions given by Jenghiz Khan to his son Jagatai were involved in the quarrels between Kaidu and Kublai for the khakanate, but at the beginning of the 14th century Dua, a great-great-grandson of Jagatai, made himself undisputed lord of the whole region. Shortly after Dua's death the Mongols of Eastern Turkestan, descendants of those who had favoured the pretensions of Kaidu to be khakan, separated from their western brethren and chose a son of Dua as their khan. Henceforth the Jagataids were divided into two dynasties, the western reigning at Samarkand, the eastern first at Kashgar and later at Yarkand and Aksu. Kazan (1343–1346) was the last independent khan of the western Jagataids; thereafter power fell into the hands of amirs, who, however, continued to place a titular khan on the throne. In 1360 Toghluk-Timur, a grandson of Dua and khan of the eastern Jagataids (the kingdom called by the Persian historians Mogolistan), invaded the territories of the western Jagataids. About this time Timur (*q.v.*), otherwise Timur-i-leng (Tamerlane), a young amir at the court of the western Jagataids, allied himself with the leaders who had dethroned Kazan, and after the death of Toghluk-Timur became by right of conquest khan of both sections of the Jagataids. After Timur's death the two sections again divided, while a third kingdom, Ferghana, was held by the Timurids (descendants of Timur). At the beginning of the 16th century all three dynasties were swept away by Mahommed Shaībani, head of the Uzbeg Mongols (see *infra*, *Uzbegs*).

The Ilkhans of Persia.

The empire of the Ilkhans established by Hulagu lasted nominally until 1353, but after the death of the Ilkhan Abu Said in 1335 the real power was divided between five petty dynasties which had been formed out of the provinces conquered by Hulagu. Meantime Islam had made great progress among the Mongols, the third Ilkhan, Nikudar Ahmed (reigned 1281–1284) having embraced that faith. The western frontiers of their empire bordering on the Syrian possessions of Egypt there was frequent intercourse, sometimes friendly, sometimes warlike, between the Ilkhans and the sultans of Egypt (*q.v.*). Of the petty dynasties which supplanted that of Hulagu, one known as the Jelairids held Bagdad until about 1400. Another dynasty which reigned in Azerbaijan was overthrown in 1355 by the western Kipchaks (see *infra*, *Golden Horde*). Between 1369 and 1400 Timur had made himself master of the greater part of Persia and established there a second Mongol dynasty, which in turn gave place to that of the Ak Kuyunli (see PERSIA).

The Golden Horde.

Of the Mongol tribes who became entirely subject to Russia the principal are those of the Crimea, of Kazan, and Astrakhan; of these the Tatars of Kazan are the truest representatives of the Golden Horde or western Kipchaks, who originally formed the subjects of Batu and Orda. Batu, whose victorious campaign in Russia has already been sketched, was finally awarded as his fief the vast steppes which stretch from the Carpathian Mountains to Lake Balkash. He fixed his headquarters on the Volga, and there set up his Golden Tent from which the horde acquired the name of the Golden Horde. In 1255 Batu died and was succeeded by his brother Bereke Khan. During the reign of this sovereign the exactions which were demanded from the Russian Christians by the Mongols aroused the Christian world against the barbarian conquerors, and at the command of Pope Alexander IV. a general crusade was preached against them. But though the rage of the Christians was great, they lacked that united energy which might have availed them against their enemies; and, while they were yet breathing out denunciations, a Tatar host, led by Nogai and Tulabagha, appeared in Poland. After a rapid and triumphant march the invaders took and destroyed Cracow, and from thence advanced as far as Bythom (Beuthen) in Oppeln, from which point they eventually retired, carrying with them a crowd of Christian slaves. From this time the Mongols became for a season an important factor in European politics. They corresponded and treated with the European sovereigns, and intermarried with royal families. Hulagu married a daughter of Michael Palaeologus; Toktu Khan took as his wife Maria, the daughter of Andronicus II.; and to Nogai Michael betrothed his daughter Irene. Toktu, the second khan in succession to Bereke, is the first Mongol ruler whom we hear of as having struck coins. Those issued during his reign bear the mint marks of Sarai, New Sarai, Bulgar, Ukek, Khwarizm, Krim, Jullad and Madjarui, and vary in date from 1291 to 1312.

The adoption of Islam by the rulers of the Golden Horde had as one result the drawing closer of the relations of the Mongols with Constantinople and Egypt. Embassies passed between the three courts, and so important was the alliance with the Mongols deemed by the sultan Nāṣir, ruler of Egypt, that he sent to demand in marriage a princess of the house of Jenghiz Khan. At first his request was refused by the proud Mongols, but the present of a million gold dinars, besides a number of horses and suits of armour, changed the refusal into an acquiescence, and in October 1319 the princess landed at Alexandria in regal state. Her reception at Cairo was accompanied with feasting and rejoicing, and the members of her escort were sent back laden with presents. With that religious toleration common to his race, Uzbeg Khan, having married one princess to Nāṣir, gave another in marriage to George the prince of Moscow, whose cause he espoused in a quarrel existing between that prince and his uncle, the grand-prince Michael. Assuming the attitude of a judge in the dispute, Uzbeg Khan summoned Michael to appear before him, and, having given his decision against him, ordered his execution. The sentence was carried out with aggravated cruelty in sight of his nephew and accuser. From this time Uzbeg's sympathies turned towards Christianity. He protected the Russian churches within his frontiers, and put his seal to his new religious views by marrying a daughter of the Greek emperor, Andronicus III. He died in 1340, after a reign of twenty-eight years. His coins were struck at Sarai, Khwarizm, Mokshi, Bulgar, Azak and Krim, and are dated from 1313 to 1340. His son and successor, Tinibeg Khan, after a reign of only a few months, was murdered by his brother Janibeg Khan, who usurped his throne, and, according to the historian Ibn Haidar, proved himself to be "just, God-fearing, and the patron of the meritorious." These excellent qualities did not, however, prevent his making a raid into Poland, which was conducted in the usual Mongol manner, nor did they save his countrymen from being decimated by the black plague. The throne Janibeg had seized by violence was, in 1357, snatched from him by violence. As he lay ill on his return from a successful expedition against Persia he was murdered by his son Berdibeg, who in his turn was, after a short reign, murdered by his son Kulpa. With the death of Berdibeg the fortunes of the Golden Horde began rapidly to decline. As the Uzbeg proverb says, "The hump of the camel was cut off in the person of Berdibeg."

The White Horde, or Eastern Kipchak.

But while the power of the Golden Horde was dwindling away, the White Horde or Eastern Kipchak, which was the inheritance of the elder branch of the family of Juji, remained prosperous and full of vitality. The descendants of Orda, Batu's elder brother, being far removed from the dangerous influences of European courts, maintained much of the simplicity and vigour of their nomad ancestors, and the throne descended from father to son with undiminished authority until the reign of Urus Khan (1360), when complications arose which changed the fortunes of the tribe. Like many other opponents of the Mongol rulers, Khan Tuli Khoja paid with his life for his temerity in opposing the political schemes of his connexion Urus Khan. Toktamish, the son of the murdered man, fled at the news of his father's death and sought refuge at the court of Timur, who received him with honour and at once agreed to espouse his cause. With this intention he despatched a force against Urus Khan, and gained some advantage over him, but, while fitting out another army to make a fresh attack, news reached him of the death of Urus. Only at Sighnak are coins known to have been struck during the reign of Urus, and these bear date from 1372 to 1375.

The Reign of Toktamish.

Moscow Sacked.

Wars with Timur.

He was followed on the throne by his two sons, Tuktakia and Timur Malik, each in turn; the first reigned but for a few weeks, and the second was killed in a battle against Toktamish, the son of his father's enemy. Toktamish now (1378) seized the throne, not only of Eastern Kipchak but also of the Golden Horde, over which his arms had at the same time proved victorious. He reigned as Nāṣir ed-din Jetal ed Mahmud Ghujas Toktamish. His demands for tribute from the Russian princes met with evasions from men who had grown accustomed to the diminished power of the later rulers of the Golden Horde, and Toktamish therefore at once marched an army into Russia. Having captured Serpukhov, he advanced on Moscow. On the 23rd of August 1382 his troops appeared before the doomed city. For some days the inhabitants bravely withstood the constant attacks on the walls, but failed in their resistance to the stratagems which were so common a phase in Mongolian warfare. With astonishing credulity they opened the gates to the Mongols, who declared themselves the enemies of the grand-prince alone, and not of the people. The usual result followed. The Russian general, who was invited to Toktamish's tent, was there slain and at the same time the signal was given for a general slaughter. Without discriminating age or sex, the Mongol troops butchered the wretched inhabitants without mercy, and, having made the streets desolate and the houses tenantless, they first plundered the city and then gave it over to the flames. The same pitiless fate overtook Vladimir, Zvenigorod, Yuriev, Mozhaisk and Dimitrov. With better fortune, the inhabitants of Pereslavl and Kolomna escaped with their lives from the troops of Toktamish, but at the expense of their cities, which were burned to the ground. Satisfied with his conquests, the khan returned homewards, traversing and plundering the principality of Ryazan on his way. Flushed with success, Toktamish demanded from his patron Timur the restoration of Khwarizm, which had fallen into the hands of the latter at a period when disorder reigned in the Golden Horde. Such a request was not likely to be well received by Timur, and, in answer to his positive refusal to yield the city, Toktamish marched an army of 90,000 men against Tabriz. After a siege of eight days the city was taken by assault and ruthlessly ravaged. In the meantime Timur was collecting forces to punish his rebellious protégé. When his plans were fully matured, he advanced upon Old Urgenj and captured it. More merciful than Toktamish, he transported the inhabitants to Samarkand, but in order to mark his anger against the rebellious city he levelled it with the ground and sowed barley on the site where it had stood. On the banks of the Oxus he encountered his enemy, and after a bloody battle completely routed the Kipchaks, who fled in confusion. A lull followed this victory, but in 1390 Timur again took the field. To each man was given "a bow, with thirty arrows, a quiver, and a buckler. The army was mounted, and a spare horse was supplied to every two men, while a tent was furnished for every ten, and with this were two spades, a pickaxe, a sickle, a saw, an axe, an awl, a hundred needles, 8½ ℔ of cord, an ox's hide, and a strong pan." Thus equipped the army set forth on its march. After a considerable delay owing to an illness which overtook Timur his troops arrived at Kara Saman. Here envoys arrived from Toktamish bearing presents and a message asking pardon for his past conduct; but Timur was inexorable, and, though he treated the messengers with consideration, he paid no attention to their prayer. In face of innumerable difficulties, as well as of cold, hunger, and weariness, Timur marched forward month after month through the Kipchak country in pursuit of Toktamish. At last, on the 18th of June, he overtook him at Kandurcha, in the country of the Bulgars, and at once forced him to an engagement. For three days the battle lasted, and, after inclining now to this side and now to that, victory finally decided in favour of Timur. The Kipchaks were completely routed and fled in all directions, while it is said as many as 100,000 corpses testified to the severity of the fighting.

Toktamish, though defeated, was not subdued, and in 1395 Timur found it necessary again to undertake a campaign against him. This time the armies met upon the Terek, and after a fiercely-contested battle the Kipchaks again fled in confusion. Timur, threatened by the advancing autumn, gave up further pursuit, and retired with a vast booty of gold ingots, silver bars, pieces of Antioch linen and of the embroidered cloth of Russia, &c. On his homeward march southwards he arrived before Azak, which was then the entrepôt where the merchants of the east and west exchanged their wares. In vain the natives, with the Egyptian, Venetian, Genoese, Catalan and Basque inhabitants, besought him to spare the city. His answer was a command to the Moslems to separate themselves from the rest of the people, whom he put to the sword, and then gave the city over to the flames. Circassia and Georgia next felt his iron heel, and the fastnesses of the central Caucasus were one and all destroyed. After these successes Timur gave himself up for a time to feasting and rejoicing, accompanied by every manifestation of Oriental luxury. "His tent of audience was hung with silk, its poles were golden, or probably covered with golden plates, the nails being silver; his throne was of gold, enriched with precious stones; the floor was sprinkled with rose water." But his vengeance was not satisfied, and, having refreshed his troops by this halt, he marched northwards against Astrakhan, which he utterly destroyed. The inhabitants were driven out into the country to perish with the cold, while the commander of the city was killed by being forced beneath the ice of the Volga. Sarai next shared the same fate, and, Timur, having thus crushed for the second time the empire of Toktamish, set out on his return home by way of Derbent and Azērbāijān.

The power in the hands of the successors of Toktamish never revived after the last campaign of Timur. They were constantly engaged in wars with the Russians and the Krim Tatars, with whom the Russians had allied themselves, and by degrees their empire decayed, until, on the seizure and death of Ahmed Khan at the beginning of the 16th century, the domination of the Golden Horde came to an end.

The Krim Tatars.

The fate which thus overtook the Golden Horde was destined to be shared by all the western branches of the great Mongol family. The khans of Kazan and Kasimov had already in 1552 succumbed to the growing power of Russia, and the Krim Tatars were next to fall under the same yoke. In the 15th century, when the Krim Tatars first appear as an independent power, they attempted to strengthen their position by allying themselves with the Russians, to whom they looked for help against the attacks of the Golden Horde. But while they were in this state of dependence another power arose in eastern Asia which modified the political events of that region. In 1453 Constantinople was taken by the Osmanli Turks, who, having quarrelled with the Genoese merchants who monopolized the trade on the Black Sea, sent an expedition into the Crimea to punish the presumptuous traders. The power which had captured Constantinople was not likely to be held in check by any forces at the disposal of the Genoese, and without any serious opposition Kaffa, Sudak, Balaklava and Inkerman fell before the troops of the sultan Mahommed. It was plain that, situated as the Crimea was between the two great powers of Russia and Turkey, it must of necessity fall under the direction of one of them. Which it should be was decided by the invasion of the Turks, who restored Mengli Girai, the deposed khan, to the throne, and virtually converted the khanate into a dependency of Constantinople. But though under the tutelage of Turkey, Mengli Girai, whose leading policy seems to have been the desire to strengthen himself against the khans of the Golden Horde, formed a close alliance with the grand-prince Ivan of Russia. One result of this friendship was that the Mongols were enabled, and encouraged, to indulge their predatory habits at the expense of the enemies of Russia, and in this way both Lithuania and Poland suffered terribly from their incursions. It was destined, however, that in their turn the Russians should not escape from the marauding tendencies of their allies, for, on pretext of a quarrel with reference to the succession to the Kazan throne, Mahommed Girai Khan in 1521 marched an army northwards until, after having devastated the country, massacred the people, and desecrated the churches on his route, he arrived at the heights of Vorobiev overlooking Moscow. The terror of the unfortunate inhabitants at the sight once again of the dreaded Mongols was extreme; but the horrors which had accompanied similar past visitations were happily averted by a treaty, by which the grand-prince Basil undertook to pay a perpetual tribute to the Krim khans. This, however, proved but a truce. It was impossible that an aggressive state like Russia should live in friendship with a marauding power like that of the Krim Tatars. The primary cause of contention was the khanate of Kazan, which was recovered by the Mongols, and lost again to Russia with that of Astrakhan in 1555. The sultan, however, declined to accept this condition of things as final, and instigated Devlet Girai, the Krim khan, to attempt their recovery. With this object the latter marched an army northwards, where, finding the road to Moscow unprotected, he pushed on in the direction of that ill-starred city. On arriving before its walls he found a large Russian force occupying the suburbs. With these, however, he was saved from an encounter, for just as his foremost men approached the town a fire broke out, which, in consequence of the high wind blowing at the time, spread with frightful rapidity, and in the space of six hours destroyed all the churches, palaces and houses, with the exception of the Kremlin, within a compass of 30 miles. Thousands of the inhabitants perished in the flames. "The river and ditches about Moscow," says Horsey, "were stopped and filled with the multitudes of people, laden with gold, silver, jewels, chains, ear-rings and treasures. So many thousands were there burned and drowned that the river could not be cleaned for twelve months afterwards." Satisfied with the destruction he had indirectly caused, and unwilling to attack the Kremlin, the khan withdrew to the Crimea, ravaging the country as he went. Another invasion of Russia, a few years later (1572), was not so fortunate for the Mongols, who suffered a severe defeat near Molodi, 50 versts from Moscow. A campaign against Persia made a diversion in the wars which were constantly waged between the Krim khan and the Russians, Cossacks and Poles. So hardly were these last pressed by their pertinacious enemies in 1649 that they bound themselves by treaty to pay an annual subsidy to the khan. But the fortunes of war were not always on the side of the Tatars, and with the advent of Peter the Great to the Russian throne the power of the Krim Mongols began to decline. In 1696 the tsar, supported by a large Cossack force under Mazeppa, took the field against Selim Girai Khan, and gained such successes that the latter was compelled to cede Azov to him. By a turn of the wheel of fortune the khan had the satisfaction in 1711 of having it restored to him by treaty; but this was the last real success that attended the Tatar arms. In 1735 the Russians in their turn invaded the Crimea, captured the celebrated lines of Perekop, and ravaged Bakhchi-sarai, the capital. The inevitable fate which was hanging over the Krim Tatars was now being rapidly accomplished. In 1783 the Krim, together with the eastern portion of the land of the Nogais, became absorbed into the Russian province of Taurida.

The Uzbegs.

It will now only be necessary to refer briefly to the Uzbegs, who, on the destruction of the Golden Horde, assumed an important position on the east of the Caspian Sea. The founder of their greatness was the khan Abulkhair, who reigned in the 15th century, and who, like another Jenghiz Khan, consolidated a power out of a number of small clans, and added lustre to it by his successful wars. Shaibani Khan, his grandson, proved himself a worthy successor, and by him Baber (*q.v.*), the Timurid khan of Ferghana, who afterwards founded the Mogul Empire in India, was driven from his ancestral dominions. In 1500 he inflicted a severe defeat on Baber's forces, and captured Samarkand, Herat and Kandahar. By these and other conquests he became possessed of all the country between the Oxus and the Jaxartes, of Ferghana, Khwarizm and Hissar, as well as of the territory of Tashkent from Kashgar to the frontiers of China. In the following year, by a dashing exploit, Baber recovered Samarkand, but only to lose it again a few months later. During several succeeding years Shaibani's arms proved victorious in many fields of battle, and but for an indiscreet outrage on the territories of the shah of Persia he might have left behind him a powerful empire. The anger, however, of Shah Ismail roused against him a force before which he was destined to fall. The two armies met in the neighbourhood of Merv, where, after a desperate encounter, the Uzbegs were completely defeated. Shaibani, with a few followers, sought refuge in a cattle-pound. But finding no exit on the farther side, the refugees tried to leap their horses over the wall. In this attempt Shaibani was killed (1510). When his body was recognized by his exultant enemies they cut off the head and presented it to the shah, who caused the skull to be mounted in gold and to be converted into a drinking-cup. After this defeat the Uzbegs withdrew across the Oxus and abandoned Khorāsān. Farther east the news aroused Baber to renewed activity, and before long he reoccupied Samarkand and the province "Beyond the River," which had been dominated by the Uzbegs for nine years. But though the Uzbegs were defeated they were by no means crushed, and ere long we find their khans reigning, now at Samarkand, and now at Bokhara. As time advanced and European powers began to encroach more and more into Asia, the history of the khanates ceases to be confined to the internecine struggles of rival khans. Even Bokhara was not beyond the reach of Russian ambition and English diplomacy. Several European envoys found their way thither during the first half of the 19th century, and the murder of Stoddart and Conolly in 1842 forms a melancholy episode in British relations with that fanatical capital. With the absorption of the khanate of Bokhara and the capture of Khiva by the Russians the individual history of the Mongol tribes in Central Asia comes to an end, and their name has left its imprint only on the dreary stretch of Chinese-owned country from Manchuria to the Altai Mountains, and to the equally unattractive country in the neighbourhood of the Koko-nōr.

(R. K. D.)

Language.—The Mongol tongue is one of the members of the great stock which recent scholars designate as Ural-Altaic, which also includes the Finno-Ugric, Turkish, Manchu and Samoyede. The members of this group are not so closely related to one another as those of the Indo-European stock; but they are all bound together by the common principle of agglutinative formation, especially the so-called harmony of vowels, by their grammatical structure, and also by certain common elements in the stock of roots which run through them all, or through particular more closely-connected families within the group.[1] The fatherland proper of the Mongols is Mongolia (*q.v.*). The sum total of the Mongol population under Chinese government is calculated at between two and three millions.

Generally the whole Mongol tribe may be divided into three branches: East Mongols, West Mongols and Buriats.

1. The East Mongols are divided into the Kalkas in the borders just mentioned, the Shara Mongols south of the Gobi along the Great Wall north-eastward to Manchuria, and lastly the Shiraigol or Sharaigol in Tangut and in northern Tibet.

---

[1] Compare W. Schott, *Versuch über die tatarischen Sprachen* (Berlin, 1836); *Ueber das altai'sche oder finnisch-tatarische Sprachengeschlecht* (Berlin, 1849); *Altajische Studien*, parts i.–v. (Berlin, 1860–1870); and A. Castrén, *Ethnologische Vorlesungen über die Altai'schen Völker*, ed. by A. Schiefner (St Petersburg, 1857).

2. On the signification and employment of the different names of the West Mongols (Kalmucks, Oelōd, Oirad or Dōrbōn Oirad = the four Oirad, Mongol Oirad), and also as regards the subdivision of the tribes, there is much uncertainty. The name Kalmuck, so generally employed among us, is in fact only used by the Volga Kalmucks (Khalimak), but even with them the name is not common, and almost a byname. It is of foreign origin, and most likely a Tataric word which has yet to be explained. *Oirad* means the "near ones," the "related." The usual explanation given is that the single tribes consider themselves as being related to each other—hence *Mongol Oirad*, "the Mongol related tribe." This is the favourite name among Kalmucks. Dōrbōn Oirad, or the four related tribes, comprise (1) Dzungars, (2) Torgod, (3) Koshod, (4) Derbet. The signification of the name *Oelōd*, in the East Mongolian *Oegeled*, now the most widely-spread among the tribes living in China, is likewise very doubtful. Some assert that "Oelōd" is nothing but the Chinese transcription of Oirad, as the ordinary Chinese language does not possess the sound *r*. We have, however, to bear in mind that we have a Mongolian root *ōgelekū*, with the sense "to be inimical," "to bear hatred, ill-will," &c. The main population of the Kalmucks live, or rather drag out, their existence after the usual fashion of nomad tribes in Dzungaria, in the eastern part of the Tian-shan, on the south border of the Gobi, on Kōkō-nōr, and in the province of Kan-suh. All these are under the Chinese government. In consequence, however, of the extension of the Russian empire in Tian-shan and Alatau, many hordes have come under the Russian sway. According to an approximate account we may reckon in the territory Semiryetshensk (Kulja) and Semipalatinsk 34,000 Kalmucks, while in the southern part of the government Tomsk, on the Altai, the Kalmuck population amounted formerly to 19,000. Besides these we find a section of Kalmuck population far in the west, on the banks of the Volga (near Astrakhan). From their original seats in Dzungaria they turned in their migrations to the north, crossed the steppe of the Kirghiz, and thus gradually reached the Emba and the Or. Between these two rivers and the Ural the Torgod settled in 1616; thence they crossed the Volga in 1650, and took possession of the now so-called steppe of the Kalmucks, being followed in 1673 by the Derbet and in 1675 by the Koshod. In 1771 a considerable number returned to the Chinese empire. There is still a not unimportant population in the so-called steppe of the Kalmucks, which extends between the Caspian and the Volga in the east and the Don in the west, and from the town of Sarepta in the north to the Kuma and the Manych in the south. According to modern statistical accounts, this population amounts to 76,000. To these we have to add 25,000 more on the borders of the Cossacks of the Don, and lastly 8000 in the bordering provinces of Orenburg and Saratov.

3. In the southern part of the Russian province of Irkutsk, in a wide circle round Lake Baikal, lies the heirdom proper of the Buriats, which they also call the "Holy Sea"; the country east of the lake is commonly called Transbiakalia. Their country practically extends from the Chinese frontier on the south within almost parallel lines to the north, to the town Kirensk on the Lena, and from the Onon in the east to the Oka, a tributary of the Angara, in the west, and still farther west towards Nizhni-Udinsk. They are most numerous beyond the Baikal Lake, in the valleys along the Uda, the Onon and the Selenga, and in Nertchinsk. These Transbaikalian Buriats came to these parts only towards the end of the 17th century from the Kalkas. While Mongols and Kalmucks generally continue to live after the usual fashion of nomads, we find here agricultural pursuits, most likely, however, due mainly to Russian influence. Christianity is also making its way. The sum total of the Buriats amounts to about 250,000.

Another tribe separated from the rest of the Mongols is the so-called Hazāra (the thousand), and the four Aimak (*i.e.* tribes), who wander about as herdsmen in Afghanistan, between Herat and Kabul. In external characteristics they are Mongols, and in all probability they are the remains of a tribe from the time of the Mongol dynasty. Their language, which shows, of course, Persian influence, is strictly Mongolian, more particularly West Mongolian or Kalmuck, as has been proved by H. C. von der Gabelentz.[1]

Agreeably with this threefold division of the Mongols we have also a threefold division of their respective languages: (1) East Mongolian or Mongolian proper, (2) West Mongolian or Kalmuck, (3) Buriatic.

The dialects just mentioned are found to be in close relation to each other when we examine their roots, inflections and grammatical structure. The difference between them is indeed so slight that whoever understands one of them understands all. Phonetically a characteristic of them all is the "harmony of vowels," which are divided into two chief classes: the hard *a*, *o*, *u* and the soft *e*, *ō*, *ū*, between which *i* is in the middle. All vowels of the same word must necessarily belong to the same class, so that the nature of the first or root-vowel determines the nature of the other or inflection-vowels; now and then a sort of retrogressive harmony takes place, so that a later vowel determines the nature of the former. The consonants preceding the vowels are equally under their influence.

The Mongolian characters, which in a slightly altered form are also in use among the Manchus, are written perpendicularly from above downward, and the lines follow from left to right, the alphabet having signs for seven vowels—*a*, *e*, *i*, *o*, *u*, *ō*, *ū*, and diphthongs derived from them—*ao*, *ai*, *ei*, *ii*, *oi*, *ui*, *ōi ūi*, and for seventeen consonants—*n*, *b*, *kh*, *gh*, *k*, *g*, *m*, *l*, *r* (never initial), *t*, *d*, *y*, *s*, (*ds*), *ts*, *ss*, *sh*, *w*. All these are modified in shape according to their position, in the beginning, middle, or end of a word, and also by certain orthographic rules. In Mongolian and Manchu writing the syllable (*i.e.* the consonant together with the vowel) is considered as a unit, in other words a syllabarium rather than an alphabet. The existing characters are lineal descendants of the original Uighurian forms, which were themselves derived from the Syriac, having been brought to the Uighurs by Nestorian missionaries. An Indian and Tibetan influence may also be noticed, while the arrangement of the characters in perpendicular lines is common to the Chinese. The writing was brought into its present shape by the learned Lamas Saskya Pandita, Phags-pa Lama, and Tshoitshi Odser in the 13th century,[2] but is exceedingly imperfect. To express the frequently-occurring letters borrowed from Sanskrit and Tibetan, which are wanting in the Mongol alphabet, a special alphabet, called Galik, is employed. Every one who has tried to read Mongolian knows how many difficulties have to be overcome, arising from the ambiguity of certain letters, or from the fact that the same sign is to be pronounced differently, according to its position in the word. Thus, there are no means for distinguishing the *o* and *u*, *ō* and *ū*, the consonants *g* and *k*, *t* and *d*, *y* and *s* (*ds*). *A* and *e*, *o* (*u*) and *ō* (*ū*), *a* (*e*) and *n*, *g* and *kh*, *t* (*d*) and *on*, are liable to be mistaken for each other. Other changes will be noticed and avoided by advanced students. It is a great defect that such common words as *ada* (*a fury*) and *ende* (here), *ende* (here) and *nada* (me), *aldan* (fathom) and *altan* (gold), *ordu* (court-residence) and *urtu* (long), *onokhu* (to seize) and *unukhu* (to ride), *tere* (this) and *dere* (pillow), *gebe* (said) and *kebe* (made), *gem* (evil) and *kem* (measure), *ger* (house) and *ker* (how), *naran* (sun) and *nere* (name), *yagon* (what) and *dsagon* (hundred), should be written exactly alike. This list might be largely increased. These defects apply equally to the Mongolian and Buriatic alphabets.

In 1648 the Saya Pandita composed a new alphabet (the Kalmuck), in which these ambiguities are avoided, though the graphic differences between the two alphabets are only slight. The Kalmuck alphabet avoids the angular and clumsy shapes of the Mongolian, and has, on the contrary, a rounded and pleasing shape. The Kalmuck alphabet has also this great advantage—that every sound has its distinct graphic character; a mistake between two characters can scarcely occur. The Kalmuck words once mastered, they can be easily recognized in their Mongolian shape. The dialectical differences are also very slight.

The Kalmuck, therefore, is the key of the Mongolian, and should form the groundwork of Mongolian studies. The Kalmuck and East Mongolian dialects do not differ much, at least in the spoken language; but the Kalmucks write according to their pronunciation, while the Mongols do not. For example, *sōn* (*dsōn*), "hundred," is pronounced alike by the Kalmucks and the East Mongolians; but according to Mongolian orthography the word appears in the form *dsagon*. The dialectic difference between the two dialects very frequently lies only in a different pronunciation of some letters. Thus East Mongolian *ds* is in Kalmuck soft *s*, &c. The chief difference between the two dialects lies in the fact that in Kalmuck the soft guttural *g* between two vowels is omitted, while, through the joining of the two vowels, a long vowel is produced. In the pronunciation of common East Mongolian the *g* is likewise omitted, but it is written, while in Kalmuck, as just now mentioned, the guttural can only be traced through the lengthening of the syllable. Thus we find: Mongol *khagan*, "prince," Kalmuck *khān*: M. *dagon*, "voice, sound," K. *dōn*, *dūn*, M. *dologan*, "seven," K. *dolōn*; M. *agola*, "mountain," K. *ōla*, *ūla*; M. *nagor*, "lake," K. *nōr*, *nūr*; M. *ulagan*, "red," K. *ulān*; M. *yagon*, "what," K. *yōn* (*yūn*); M. *dabagan*, "mountain ridge," K. *dabān*; M. *ssanagan*, "thought," K. *ssanān*; M. *baragon*, "on the right," K. *barōn*, *barūn*; M. *shibagon*, "bird," K. *showōn*; M. *chilagon*, "stone," K. *chilōn* (*chulūn*); M. *jirgogan*, "six," K. *surgān*; M. *degere*, "high, above," K. *dēre*; M. *ugukhu*, "to drink," K. *ūkhu*; M. *togodshi*, "history," K. *tōdshi*, *tūdshi*; M. *egūden*, "door," K. *ōden*; M. *dsegūn*, "left," K. *sōn*; M. *ōgede*, "in the height," K. *ōdo*; M. *ōgeled*, "the Kalmucks," K. *ōlōd*; M. *ūileged*, "if one has done," K. *ūilēd*, M. *kōbegūn*, "son," K. *kōwōn*; M. *gegūn*, "mare," K. *gūn*; M. *kegūr*, "corpse." K. *kūr*; M. *kharigad*, "returned," K. *kharēd*, &c.

The Buriatic, in these peculiarities, is almost always found with East Mongolian, with which it is in every respect closely allied. In the pronunciation of some letters the transition of East Mongolian *tsa*, *tse* into Buriatic *ss* is noticeable; for instance: Mong. *tsetsek* "flower," Buriatic *ssessek*; M. *tsak*, "time," B. *ssak*; M. *tsagan* "white," B. *ssagan*; M. *tsetsen*, "prudent," B. *ssessen*. *Ss* is sometimes pronounced like (the German) *ch*: East M. *ssain*, "good," B

---

[1] See his essay, "Ueber die Sprache der Hazāras und Aimaks," in the *Zeitschrift der deutschen morgenländischen Gesellschaft*, xx. 326–335.

[2] Cf. H. C. von der Gabelentz, in the *Zeitschrift f. d. Kunde d Morgenlandes* (Göttingen, 1838), ii. 1–21, "Versuch über eine alte mongolische Inschrift."

chain; M. *ssedkil*, "heart," B. *chedkil*. *K* in the beginning or middle of a word is always aspirated.

The noun is declined by the help of appended particles, some of which are independent post-positions, viz. Gen. *yin*, *u*, *un*; Dat. *dur*, *a*; Acc. *yi*, *i*; Ablat. *etse*; Instrum. *ber*, *yer*; Associative, *luga*, *lūge*. The dative and accusative have also special forms which have at the same time a possessive sense, viz. Dat. *dagan*, *degen*; Accus. *ben*, *yen*. The plural is expressed by affixes (*nar*, *ner*, *od*, *ss*, *d*), or frequently by words of plurality, "all," "many," *e.g.* *kūmūn nogōd* (man, many=men). The oblique cases have the same endings in singular and plural. Gender is not indicated. The adjective is uninflected both as attribute and as predicate; there is no comparative form, this idea being expressed by the construction or by the use of certain particles. The personal pronouns are *bi*, I; *tchi*, thou; *bida*, we; *ta*, ye; their genitives serve as possessives. The demonstratives are *ene*, *tere* (this, that), plural *ede*, *tede*; interrogative *ken*, who? The relative is lacking, and its place is supplied by circumlocutions. The numerals are: 1, *nigen*; 2, *khoyar*; 3, *gurban*; 4, *dōrben*; 5, *tabun*; 6, *jirgugan*; 7, *dologan*; 8, *naiman*; 9, *yisun*; 10, *arban*; 100, *dsagon*; 1000, *minggan*. The ordinals are formed by appending *tugar*, *tūger*. The theme of the verb is seen in the imperative, as *bari*, grasp. The conjugation is rich in forms for tense and mood, but the person and number are with few exceptions unexpressed. The present is formed from the theme by adding *mui* (*barimui*), the preterite by *bai* or *luga* (*baribai*, *bariluga*), the future by *ssugai* or *ssu* (*barissugai*, *barissu*). The preterite has also in the third person the terminations *dsugui* and *run*; the future has in the third person *yu*, and in the first *ya*. The conditional ends in *bassu* (*baribassu*), the precative in *tugai*, *tūgei*, the potential in *sa* (*barimuisa*), the imperative plural in *ktun*, the gerund in the present in *n*, *dsu* (*barin*, *baridsu*) or *tala*, "while, till" (*baritala*, "inter capiendum"), in the preterite it is formed in *gad* (*barigad*); the present part. has *ktchi* (*bariktchi*), the past part. *kssan* (*barikssan*); the supine ends in *ra*, the infinitive in *khu* (*barikhu*, or when used substantively *barikhui*). There is but one perfectly regular conjugation, and derivative forms, derived from the theme by infixes, are conjugated on the same scheme. Thus the passive has infixed *ta* or *kda* (*barikdakhu*, to be grasped), the causative *gul* (*barigulkhu*, to cause to grasp), the co-operative or sociative *ltsa* or *lda* (*bariltsakhu*, to grasp together).

There are no prepositions, only post-positions. Adverbs are either simple particles (affirmative, negative, interrogative, modal, &c.) or are formed by suffixes from other parts of speech. There are very few conjunctions; the relations of clauses and sentences are mainly indicated by the verbal forms (part., sup., conditional, but mainly by the gerund).

The order of words and sentences in construction is pretty much the opposite of that which we follow. In a simple sentence the indication of time and place, whether given by an adverb or a substantive with a post-position, always comes first; then comes the subject, always preceded by its adjective or genitive, then the object and other cases depending on the verb, last of all the verb itself preceded by any adverbs that belong to it. So in the structure of a period all causal, hypothetical, concessive clauses, which can be conceived as preceding the main predication in point of time, or even as contemporary with it, or as in any way modifying it, must come first; the finite verb appears only at the end of the main predication or apodosis. The periods are longer than in other languages; a single one may fill several pages.

Authorities.—Grammars and dictionaries may be divided according to the three dialects. For East Mongolian, I. J. Schmidt gave the first grammar (St Petersburg, 1831), and a Mongolian-German-Russian dictionary (St Petersburg, 1835). Next Jos. Kovalevski published in Russian a Mongolian grammar (Kasan, 1835), a chrestomathy (2 vols., Kasan, 1836, 1837), and his great *Dictionnaire mongol-russe-français* (3 vols., Kasan, 1844, 1846, 1849). We may mention R. Yuille, *Short Mongolian Grammar* (in Mongolian), xylographed at the mission press near Selenginsk beyond Lake Baikal (1838). A. Bobrovnikov's Russian *Grammar of the Mongolian-Kalmuck Language* (Kasan, 1849) is also very good. An abridgment of Schmidt's work is C. Puini, *Elementi della grammatica mongolica* (Florence, 1878). A. Popov's *Mongolian Chrestomathy* appeared in 2 vols. at Kasan (1836). For the Kalmuck we have grammars by Popov (Kasan, 1847), Bobrovnikov, as above, and H. A. Zwick (*s. l. et a.*), autographed at Donaueschingen (1851). Zwick's autographed Kalmuck and German dictionary with a printed German index appeared (*s. l. et a.*) in 1852; B. Jülg's edition of the tales of Siddhi-kūr (Leipzig, 1866) gives a complete glossary to these stories. There are small Russian and Kalmuck vocabularies by P. Smirnov (Kasan, 1857) and C. Golstunskyi (St Petersburg, 1860). For the Buriatic we have Castrén, *Versuch einer burjätischen Sprachlehre*, ed. by Schiefner (1857), and A. Orlov's Russian grammar of the Mongol-Buriatic colloquial language (Kasan, 1878).

Literature.—A clear distinction must be drawn between the higher and nobler written or book-language and the common or conversational language of every-day life. The difference between the two is very considerable, and may be fairly compared to that between the modern High German book-language and the different dialects. All grammars and dictionaries as yet published treat only of the book-language; and so also, with a few exceptions, the published literary documents are written in this higher style. The exceptions are the *Gesser-Khan*, and the *Siddhi-kūr* and *Djangariad* (the last two published by Golstunskyi). The popular or conversational language has been fixed in writing by A. Pozdneev in his Russian work, *Specimens of the Popular Literature of the Mongolian Tribes*, pt. i., "Popular Songs" (St Petersburg, 1880), which contains rich material for the study of the popular literature.

The literature consists mostly of translations from the Tibetan, the holy language of Buddhism, which is still the language of the learned. The Tibetan Buddhist literature is itself translated from the Sanskrit; hence, now and then, through Mongols and Kalmucks we get acquainted with Indian works the originals of which are not known in Sanskrit. Such is the case, for instance, with the tales of Siddhi-kūr. Many books have also been translated from the Chinese. Most of the writings are of a religious, historical, philosophical, medical, astronomical or astrological character. Favourite subjects are folk-lore and fairy tales. Among the religious books, perhaps the most important is that containing the legends entitled *ūliger ūn dalai*, "ocean of comparisons" (ed. by I. Jacob Schmidt under the title, *Der Weise und der Thor*, in Tibetan and German (St Petersburg, 1843). To this may be added the *boddhi mōr*, or "the holy path," the *altan gerel*, "gleaming of gold," the *mani gambo* and *yertüntchü yin toli*, "mirror of the world.". What was known of poetical literature before Pozdneev is scarcely worth mentioning. In some parts of the historical and narrative literature we find, wherever the narrative takes a higher flight, an admixture of poetical diction. The poetry appears in a certain parallelism of the phrases, with a return either of the same endings (rhyme) or of the same words (refrain). Frequently we find, besides the rhyme or refrain, alliteration. The essay of H. C. von der Gabelentz in *Z. f. d. Kunde des Morgenlandes*, i. 20–37, "Einiges über mongolische Poesie," has been superseded by the work of Pozdneev.

Among historical works a high place is due to that composed by the tribal prince, Sanang Setzen, in the middle of the 17th century (*Geschichte der Ost-Mongolen und ihres Fürstenhauses*, Mongolian and German, by I. J. Schmidt, St Petersburg, 1829), and to the *Altan tobtchi*, *i.e.* "golden knob" or "precious contents" (text and Russian trans. by the Lama Galsang Gomboyev, St Petersburg, 1858). Of folk-lore and fairy tales, we have the legend of the hero *Gesser-Khan* (text ed. by I. J. Schmidt, St Petersburg, 1836, and German version, 1839; cf. Schott, *Ueber die Sage v. Geser-Khan*, Berlin, 1851, and B. Jülg in the *Transactions* of the Würzburger Philol. Versam. of 1868, pp. 58 sqq., Leipzig, 1869); and the tales about *Ardshi Bordshi* (Russian version by Galsang Gomboyev, St Petersburg, 1858; text and German trans. by B. Jülg, Innsbruck, 1867, 1868). A favourite book is the tales of Siddhi-kūr, based on the Sanskrit *Vetâla panchavinçati* (Russian trans. by Galsang Gomboyev, St Petersburg, 1865, nine of the tales in Mongolian and German, by B. Jülg, Innsbruck, 1868). The fuller collection of these tales in Kalmuck first became known by the German trans. of B. Bergmann in vol. i. of his *Nomadische Streifereien unter d. Kalmüken* (4 vols., Riga, 1804, 1805); an autographed edition in the vulgar dialect was published by C. Golstunskyi (St Petersburg, 1864); text and German trans. with glossary by B. Jülg (Leipzig, 1866). A poetic heroic story is the *Djangariad*, extracts from which were given by Bergmann (*op. cit.*, iv. 181 sqq.); a complete Russian version by A. Bobrovnikov (St Petersburg, 1854); a German version by F. v. Erdmann in *Z.D.M.G.*, 1857 (Kalmuck text by Golstunskyi, St Petersburg, 1864). A similar poem is the history of Ubasha Khuntaidshi and his war with the Oirad, Kalmuck text and Russian trans. by G. Gomboyev in his Altan tobtchi as above, and text alone autographed by Golstunskyi (St Petersburg, 1864). Some books of religion for the Christian Buriats (transcribed in Russian characters) represent the Buriatic dialect. The Russian and English Bible Societies have given us a translation of the whole Bible. I. J. Schmidt translated the Gospels and the Acts into Mongolian and Kalmuck for the Russian Bible Society (8 vols., St Petersburg, 1819–1821)—a masterly work. The English missionaries, E. Stallybrass and W. Swan, and afterwards R. Yuille, translated the whole Old Testament into Mongolian (1836–1840). This work was printed at a mission press erected at great cost for the purpose near Selenginsk, beyond Lake Baikal in Siberia. In 1846 the New Testament by the same hands appeared at London.

Authorities.—The richest collections of Mongolian and Kalmuck printed books and MSS. are in the Asiatic museum of the St Petersburg Academy, and in the libraries of Kazan and Irkutsk; there is also a good collection in the royal library at Dresden. Consult in general, besides the already-cited works of Bergmann and Pozdneev, P. S. Pallas, *Sammlungen historischer Nachrichten ü. d. mongolischen Völkerschaften* (2 vols., St Petersburg, 1776–1801); I. J. Schmidt, *Forschungen im Gebiete der älteren . . . Bildungsgeschichte der Völker Mittelasiens, vorz. d. Mongolen und Tibeter* (St Petersburg and Leipzig, 1824); B. Jülg, "On the Present State of Mongolian Researches," *Journ. R. As. Soc.*, xiv. (1882), pp. 42–65. (B. J.)

MŌNG PAI (called *Mobyē* by the Burmese), the most southwesterly of the British Shan States of Burma. It has an approximate area of 1000 sq. m., and a population (1901) of 19,351. The general character of the country is hilly, rising westwards in a gentle slope from the chief stream, the Nam Hpilu or Balu.

This is navigable for native boats throughout the year to the point where it sinks underground in Karen-ni. The chief cultivation is rice, with about two acres of dry or hill rice to one of wet bottom. The hill fields are left fallow for ten years after two years' cultivation. The chief, the Sawbwa Hkun Yōn, held charge through the reigns of four Burmese kings, and submitted early in 1887 on the first arrival of British troops. He abdicated in favour of his son in 1890, and died a few years later.

MŌNG PAN (the Burmese *Maingpan*), a state in the eastern division of the southern Shan States, lying approximately between 19° 45′ and 20° 25′ N. and between 98° and 99° E., with an area of 2299 sq. m., and a population (1901) of 16,629. The main state lies, except for a few insignificant circles, entirely west of the Salween, but beyond that river are the four subfeudatory states of Mōng Tun, Mōng Hang, Mōng Kyawt and Mōng Hta. The only considerable area of flat land is round the capital, which lies in a large and fertile plain, marking roughly the centre of the state. From this plain rise on all sides low hills covered with scrub jungle, sloping up to ranges of about 5000 ft. on nearly every side. Rice is the only crop, irrigated where possible; elsewhere dry cultivation prevails. The state has valuable teak forests on both sides of the Salween, which cover a considerable but undetermined area. The general altitude of the valleys is about 2000 ft. The capital is small, and has only about 200 houses. The chief is of Sawbwa rank.

MONGREL (earliest form *mengrel*, probably from the root *meng-*, or *mong-*, to mix, cf. mingle, among), a dog that is the progeny of two different breeds, or one whose breed it is impossible to tell on account of the various crossings. In the case of other animals or plants it is the result of a fertile cross between two varieties of the same species, and so to be distinguished from a "hybrid," the result of a fertile cross between two distinct species (see HYBRIDISM).

MONIER-WILLIAMS, SIR MONIER (1819–1899), British orientalist, son of Colonel Monier-Williams, surveyor-general in the Bombay presidency, was born at Bombay on the 12th of November 1819. He matriculated at Oxford from Balliol College in 1837, but left the university on receiving in 1839 a nomination for the East India Company's civil service, and was completing his course of training at Haileybury when the entreaties of his mother, who had lost a son in India, prevailed upon him to relinquish his nomination and return to Oxford. As Balliol was full, he entered University College and, devoting himself to the study of Sanskrit, he gained the Boden scholarship in 1843. After taking his degree he was appointed professor of Sanskrit, Persian and Hindustani at Haileybury, where he remained until the abolition of the college upon the transfer of the government of India from the Company to the Crown. He taught oriental languages at Cheltenham for ten years, and in 1860 was elected Boden professor of Sanskrit at Oxford after a contest with Professor Max Müller (*q.v.*), which attracted great public interest and severe criticism, the motive of the non-resident voters, whose suffrages turned the scale, being notoriously not so much to put Monier-Williams in as to keep Max Müller out. Although, however, far inferior to his rival in versatility and literary talent, Monier-Williams was in no way inferior in the special field of Sanskrit, and did himself and his professorship much honour by a succession of excellent works, among which may especially be named his Sanskrit-English and English-Sanskrit dictionaries; his *Indian Wisdom* (1875), an anthology from Sanskrit literature; and his translation of *Sakuntala* (1853). In his later years he was especially attracted by the subject of the native religions of India, and wrote popular works on Brahmanism, Buddhism and Hinduism. His principal undertaking, however, was the foundation of the Indian Institute at Oxford, which owes its existence entirely to him. He brought the project before the university in May 1875, and in that year and the following, and again in 1883, visited India to solicit the moral and financial support of the native princes and other leading men. Lord Brassey came to his aid with a donation of £9000, and in November 1880 the institute was adopted by the university, but the purchase of a site and the erection of a building were left to the professor. Upwards of £30,000 was eventually collected; the prince of Wales, in memory of his visit to India, laid the foundation stone in May 1883; and the edifice, erected in three instalments, was finally completed in 1896. Ere this, failing health had compelled Monier-Williams to withdraw from the active duties of his professorship, which were discharged by the deputy-professor, Dr A. Macdonell, who afterwards succeeded him. He continued, nevertheless, to work upon Sanskrit philology until his death at Cannes on the 11th of April 1899. He had been knighted in 1886, and was made K.C.I.E. in 1889, when he adopted his Christian name of Monier as an additional surname.

MONISM (from Gr. *μόνος*, alone), the philosophic view of the world which holds that there is but one form of reality, whether that be material or spiritual. The aim of knowledge is explanation, and the dualism or pluralism which acquiesces in recognizing two or more wholly disparate forms of reality has in so far renounced explanation (see DUALISM). To this extent monism is justified; but it becomes mischievous if it prompts us to ignore important differences in facts as they present themselves to our intelligence. All forms of monism from Plotinus downwards tend to ignore personal individuality and volition, and merge all finite existence in the featureless unity of the Absolute; this, indeed, is what inspires the passion of the protest against monism. Turning to the historical forms of the theory we may class Plotinus as a mystical monist: he attains to the One which is the All by an act of mystic union raising him above the phenomenal sphere. Spinoza is a materialistic monist with an inconsistent touch of mysticism and a certain concession, more apparent than real, to the spiritual side of experience. Hegel's is an intellectualist monism, explaining matter, sensation, personal individuality and will as forms of thought. The doctrine of Schopenhauer and von Hartmann is a monism of cosmic will which submerges the individual no less completely than Hegelianism, though in a different manner. Haeckel's monism is mere materialism dignified by a higher title. Those who maintain that all these forms of synthesis are hasty and superficial stand by the conviction that the right philosophic attitude is to accept provisionally the main distinctions of common sense, above all the distinction of personal and impersonal; but to press forward to the underlying unity so far as experience and reflection justify.

See ABSOLUTE; DUALISM; METAPHYSICS; MATERIALISM; IDEALISM.

MONITION, or ADMONITION (Lat. *monere*, to admonish), in English ecclesiastical law, an order requiring or admonishing the person complained of to do something specified in the monition, or appear and show cause to the contrary, "under pain of the law and penalty thereof." It is the lightest form of ecclesiastical censure, whether to clergymen or laymen, but disobedience to it, after it has been duly and regularly served, entails the penalties of contempt of court. Monitions of a disciplinary character are either for the purpose of enforcing residence on a benefice, or in connexion with suits to restrain ritual alleged to be unlawful.

MONITOR (from Lat. *monere*, to warn, advise), an advisor or counsellor, one who warns another person as to his course of action, also used of things that are more or less personified, as conscience. The word is chiefly applied to senior pupils (also known as "prefects") in some of the great secondary schools in England; in America to senior students in certain colleges to whom special duties are assigned, particularly that of keeping order; and also to pupil teachers in English elementary schools. It is used in a general way of anything that gives warning, and in this sense is applied to a lizard of the family *Monitoridae*, or *Varanidae*, found in Africa and Australia, which is supposed to give warning of the approach of crocodiles. The name of monitor was also given to a particular kind of ironclad invented for the American navy by Captain John Ericsson (*q.v.*) in 1862, which had a very low freeboard and revolving gun-turrets. The letter of Ericsson to the assistant secretary of the navy, of the 20th of January 1862 (quoted in the *Century Dictionary*), gives the inventor's reason for the name. "The impregnable and aggressive character of this structure will admonish the leaders of the Southern Rebellion that the batteries on the banks of their rivers will no longer present barriers to the entrance of the Union forces. The ironclad intruder will thus prove a severe *monitor* to those leaders . . . 'Downing Street' will hardly view with indifference this last 'Yankee notion,' this monitor." It is also the name of an ironclad railway truck used for carrying a big gun. In America the raised part of the roof of a railway carriage or omnibus in which the lights or ventilators are placed is known as a monitor roof or top. In mining the word is applied to a jointed nozzle which may be turned in all directions, and is used in hydraulic mining.

MONK (or Monck), **GEORGE,** 1st Duke of Albemarle (1608–1669), second son of Sir Thomas Monk, a gentleman of good family but in embarrassed circumstances, was born at Potheridge, near Torrington, in Devonshire, on the 6th of December 1608. Having thrashed the under-sheriff of the county in revenge for a wrong done to his father, he had to leave home, and naturally took to the career of arms. He served as a volunteer in the expedition to Cadiz, and the next year did good service at the Isle of Rhé. In 1629 Monk went to the Low Countries, then the school of war, and there he gained a high reputation as a leader and disciplinarian. In 1638 he threw up his commission in consequence of a quarrel with the civil authorities of Dordrecht, and came to England. He obtained the lieutenant-colonelcy of Newport's regiment. During the operations on the Scottish border he showed his skill and coolness in the dispositions by which he saved the English artillery at Newburn, though himself destitute of ammunition. At the outbreak of the Irish rebellion he was appointed colonel of Lord Leicester's regiment. All the qualities for which he was noted through life—his talent of making himself indispensable, his imperturbable temper and his impenetrable secrecy—were fully displayed in this employment. The governorship of Dublin was vacant, and Monk was appointed by Leicester. But Charles I. overruled the appointment in favour of Lord Lambart, and Monk with great shrewdness gave up his claims. Ormonde, however, who viewed him with suspicion as one of the two officers who refused the oath to support the Royal cause in England, sent him under guard to Bristol. But he justified himself to Charles in person, and his soldierly criticisms on the conduct of the Irish War impressed the king, who gave him a command in the corps sent over from Ireland during the English Civil War. Monk was, however, soon taken prisoner, at Nantwich (1644), and spent the next two years in the Tower, where he found it difficult to live owing to his want of means. The king himself sent him £100, a gift for which Monk himself was sincerely grateful. He beguiled his imprisonment by writing his *Observations on Military and Political Affairs*.

Monk's Irish experience, however, led to his release and an invitation to take service in the parliament's army against the Irish rebels. Making a distinction like other soldiers of the time between fighting the Irish and taking arms against the king, he accepted the offer and took the covenant. At first as adjutant-general to the Parliamentary lord-lieutenant, his old friend Lord Lisle, and afterwards as governor of Ulster, he rendered great services to his new masters. In conjunction with Colonel Michael Jones, governor of Leinster, he made head against the rebels for two years, but in the third (1649) the Parliamentarians, weakened by defections brought about by the execution of the king, were no longer able to keep the field. Losing one strong place after another, Monk concluded an armistice with the rebel Owen Roe O'Neill upon terms which he knew the parliament would not ratify. The convention was indeed a military expedient to deal with a military necessity, and although most of his army went over to the Royalist cause, he himself remained faithful to his employers and returned to England. As he expected, parliament "utterly disapproved" of the armistice but exonerated their general. His next service was in Cromwell's army in Scotland. He commanded a brigade at the great victory of Dunbar, and afterwards captured a number of small places. When in 1651 Cromwell with the field army hurried southward into England to bring the invading Scots to battle, Monk was left behind to complete the subjugation of the country. In February 1652 he left Scotland to recruit his broken health at Bath, and in November of the same year he became an admiral, or rather a "general at sea," instead of a soldier. Ten days after hoisting his flag for the first time he was engaged with his colleagues, Blake and Deane, in the battle of Portland (Feb. 18, 1653). In the action of June 2–3 Monk exercised the general command after Deane's death. A third battle followed on the 29th and 30th of July, which was a decisive victory for the Commonwealth's fleet (see Dutch Wars). On his return he married Anne Clarges, a woman of low extraction, often supposed to have been his mistress, "ever a plain homely dowdy," says Pepys, who, like other writers who mention her, is usually still less complimentary. Next year he was back in Scotland, methodically beating down a Royalist insurrection in the Highlands, and when this service was over settled down to a steady government of the country for the next five years. The timely discovery of a plot fomented by Overton, his second in command, in 1654, gave him an excuse for thoroughly purging his army of all Anabaptists, Fifth Monarchy men, and other dangerous enthusiasts. It is improbable that at this time Monk had proposed to himself the restoration of the king, though so astute a diplomatist must have weighed the chances of such an event. His very reticence, however, caused alarm on one side and hope on the other. In 1655 he received a letter from Charles II., a copy of which he at once sent to Cromwell, who is said to have written to him in 1657 in the following terms: "There be that tell me that there is a certain cunning fellow in Scotland called George Monk, who is said to lye in wait there to introduce Charles Stuart; I pray you, use your diligence to apprehend him, and send him up to me." Monk's personal relations with Cromwell were those of sincere friendship on both sides.

During the confusion which followed Cromwell's death Monk remained silent and watchful at Edinburgh, careful only to secure his hold on his troops. At first he contemplated armed support of Richard Cromwell, but gave up this idea on realizing the young man's incapacity for government, and renewed his waiting policy. In July 1659 direct and tempting proposals were again made to him by the king. His brother Nicholas, a clergyman, was employed by Sir J. Grenvil to bring to him the substance of Charles's letter. No bribe, however, could induce him to act one moment before the right time. He bade his brother go back to his books, and refused to entertain any proposal. But when Booth rose in Cheshire for the king, so tempting did the opportunity seem that he was on the point of joining forces with him, and a manifesto was prepared. His habitual caution, however, induced him to wait until the next post from England, and the next post brought news of Booth's defeat.

For a moment he thought of retiring into private life, but soon Fleetwood and Lambart declared against the parliament, and to their surprise Monk not only refused to join them, but (Oct. 20, 1659) at once took measures of active opposition. Securing his hold on Scotland by a small but trusty corps of occupation, he crossed the border with the rest of his army. Holding Lambart in play without fighting until his army began to melt away for want of pay, Monk received the commission of commander-in-chief of the parliament's forces (Nov. 24). The navy, some of the English garrisons and the army in Ireland declared for the parliament, and the army from Scotland crossed the Tweed on the 2nd of January 1660. It was inferior in number, but in all other respects superior to Lambart's, and Monk slowly marched on to London, disbanding or taking over on his way the detachments of Lambart's army which he met, and entered the capital on the 3rd of February. In all this his ultimate purpose remained mysterious. At one moment he secretly encouraged the demands of the Royalist City of London, at another he urged submission to the existing parliament, then again he refused to swear an oath abjuring the house of Stuart, and further he hinted to the attenuated Long Parliament the urgent necessity of a dissolution. Lastly, acting as the stern military agent of the infuriated parliament, he took away the gates and portcullises of the city. This angered not only the citizens but his own army, and gave him the lever that he desired to enforce the dissolution of parliament, while at the same time enabling him to break up as a matter affecting discipline, the political camarillas that had formed in his own regiments. He was now master of the situation, and though he protested his adherence to republican principles, it was a matter of common knowledge that the new parliament, which Monk was imposing on the remnant of the old, would have a strong Royalist colour. Monk himself was now in communication with Charles II., whose Declaration of Breda was based on Monk's recommendations. The new parliament met on the 25th of April, and on the 1st of May voted the restoration of the monarchy.

With the Restoration the historic interest of Monk's career ceases. Soldier as he was, he had played the difficult game of diplomacy with incomparable skill, and had won it without firing a shot. That he was *victor sine sanguine*, as the preamble of his patent of nobility stated, was felt by every one to be the greatest service of all. He was made gentleman of the bedchamber, knight of the Garter, master of the horse and commander-in-chief, raised to the peerage with the titles of Baron Monk, earl of Torrington and duke of Albemarle, and had a pension of £7000 a year allotted to him. As long as the army existed of which he was the idol, and of which the last service was to suppress Venner's revolt, he was a person not to be displeased. But he entirely concurred in its disbandment, and only the regiment of which he was colonel, the Coldstream (Guards), survives to represent the army of the Civil Wars. In 1664 he had charge of the admiralty when James, duke of York, was in command of the fleet, and when in 1665 London was deserted on account of the plague, Monk, with all the readiness of a man accustomed to obey without thinking of risk, remained in charge of the government of the city. Once more, at the end of this year, he was called upon to fight, having a joint commission with Prince Rupert against the Dutch. The whole burden of the preparations fell upon him. On the 23rd of April 1666 the admirals joined the fleet, and on the 1st of June began the great four days' battle, in which Monk showed not only all his old coolness and skill, but also a reckless daring which had seemed hitherto foreign to his character. Later in the same year he maintained order in the city of London during the Great Fire. His last service was in 1667, when the Dutch fleet sailed up the Thames, and Monk, though ill, hastened to Chatham to oppose their farther progress. From that time he lived much in privacy, and died of dropsy on the 3rd of January 1670, "like a Roman general with all his officers about him." The dukedom became extinct on the death of his son Christopher, 2nd duke of Albemarle (1653–1688).

See the *Life* of Monk, by Dr Gumble, his chaplain (London, 1671), and the memoir and bibliography by C. H. Firth in the *Dict. Nat. Biogr.*

MONK, JAMES HENRY (1784–1856), English divine and classical scholar, was born at Buntingford, Herts. He was educated at Charterhouse School and Trinity College, Cambridge, and in 1809 was elected professor of Greek in succession to Porson. The establishment of the classical tripos was in great measure due to his efforts. In 1822 he was appointed dean of Peterborough; in 1830, bishop of Gloucester (with which the see of Bristol was amalgamated in 1836). He is best known as the author of a *Life of Bentley* (1830) and as the editor (with C. J. Blomfield) of Porson's *Adversaria* (1812).

MONK, MARIA (*c.* 1817–1850), an adventuress and impostor, who, coming to New York in 1835, claimed to have escaped from the Montreal nunnery of the Hôtel Dieu, concerning which, and the practices prevalent there, she circulated sensational charges in *Awful Disclosures by Maria Monk* (1836). Over 200,000 copies of this book and a sequel were sold, and a violent anti-Catholic agitation resulted. She was finally exposed as a woman of bad character, and her story proved to be absolutely false, but not until she had deceived many people of good standing.

MONK (O.Eng. *munuc*; this with the Teutonic forms, *e.g.* Du. *monnik*, Ger. *Mönch*, and the Romanic, *e.g.* Fr. *moine*, Ital. *monacho* and Span. *monje*, are from the Lat. *monachus*, adapted from Gr. *μοναχός*, one living alone, a solitary; *μόνος*, alone), a member of a community of men living a life under vows of religious observance; the term is properly confined to a member of a Christian community, but is sometimes applied to members of Buddhist and Mahommedan religious brotherhoods. The Greek and Latin name was first used of the hermits, but was early widened to embrace the coenobites. The term "monk" should not be used either of "friars" or of "canons regular." (See MONASTICISM.)

MONKEY, a term apparently applicable to all members of the order PRIMATES (*q.v.*) except man and perhaps the larger apes. In zoology it may be used in this wider sense, as inclusive of all the Primates except man and lemurs; but it may also be employed in a more restricted application, so as to denote all ordinary "monkeys" as distinct from baboons on the one hand and the tail-less man-like apes on the other. The word appears in English first in the 16th century. The Low-German version of *Reynard the Fox* (*Reinke de Vos*, 1479) calls the son of Martin, the ape, *Moneke*; and the French version has *Monnekin*, *Monnequin*; these are apparently Teutonic diminutives of a word for ape which occurs in several Romanic languages, *e.g.* Fr. *monne*, It. *monna*, &c.

MONKHOUSE, WILLIAM COSMO (1840–1901), English poet and critic, was born in London on the 18th of March 1840. His father, Cyril John Monkhouse, was a solicitor; his mother's maiden name was Delafosse. He was educated at St Paul's School, quitting it at seventeen to enter the board of trade as a junior supplementary clerk, from which grade he rose eventually to be the assistant-secretary to the finance department of the office. In 1870–1871 he visited South America in connexion with the hospital accommodation for seamen at Valparaiso and other ports; and he served on different departmental committees, notably that of 1894–1896 on the Mercantile Marine Fund. He was twice married: first, to Laura, daughter of James Keymer of Dartford; and, secondly, to Leonora Eliza, daughter of Commander Blount, R.N. He died in London on the 20th of July 1901. Cosmo Monkhouse was one of those who have not only a vocation, but an avocation. His first bias was to poetry, and in 1865 he issued *A Dream of Idleness and Other Poems*, a collection strongly coloured by his admiration for Wordsworth and Tennyson. It was marked by exceptional maturity, and scarcely received the recognition it deserved. Owing perhaps to this circumstance, it was not till 1890 that he put forth *Corn and Poppies*, a collection which contains at least one memorable effort in the well-known "Dead March." Five years later appeared a limited edition of the striking ballad of *The Christ upon the Hill*, illustrated with etchings by Mr William Strang. After his death his poetical output was completed by *Pasiteles the Elder and other Poems* (including *The Christ upon the Hill*). In 1868 Monkhouse essayed a novel, *A Question of Honour*. Then, after preluding with a *Life of Turner* in the "Great Artists Series" (1879), he devoted himself almost exclusively to art criticism. Besides many contributions to the *Academy*, the *Saturday Review*, the *Magazine of Art* and other periodicals, he published volumes on *The Italian Pre-Raphaelites* (1887), *The Earlier English Water-Colour Painters* (1890 and 1897), *In the National Gallery* (1895) and *British Contemporary Artists* (1899). He was a contributor to the *Dict. Nat. Biog.* from the beginning. Monkhouse also wrote an excellent *Memoir of Leigh Hunt* in the "Great Writers Series" (1887). As an art critic Monkhouse's judgments were highly valued; and he had the rare gift of differing without offending, while he invariably secured respect for his honesty and ability. As a poet, his ambition was so wide and his devotion to the art so thorough, that it is difficult not to regret the slender bulk of his legacy to posterity.

MONKSWELL, ROBERT PORRETT COLLIER, 1st BARON (1817–1886), English judge, was born at Plymouth, on the 21st of June 1817, and was the son of a prominent merchant of Quaker extraction. He was educated at Oxford, was called to the bar in 1843, and went the western circuit. He obtained a high reputation by his successful defence of Brazilian pirates in 1845;

they were, indeed, convicted at the assizes, but Collier ultimately procured their escape upon a point of law which the judge had refused to reserve. He was elected member of parliament for Plymouth in the Liberal interest in 1852, and in 1859 was appointed counsel to the admiralty and judge-advocate to the fleet. In this capacity he gave in 1862 an opinion in favour of detaining the Confederate rams building in the Mersey, which would have saved his country much money and much credit if it had been acted upon. In 1863 he became solicitor-general, and in 1868 attorney-general, and in 1869 successfully passed a bankruptcy bill. In 1871 he was appointed by Mr Gladstone one of four new judges upon the judicial committee of the privy council, although it was expressly provided by the act creating these offices that none of them should be filled by a law-officer of the Crown. This prohibition was evaded by making Collier a judge of common pleas, and transferring him after a few days to the privy council. This arrangement was unanimously condemned by public opinion, and gave the Gladstone cabinet a serious blow. He officiated, nevertheless, with distinction until his death on the 3rd of November 1886, and was raised to the peerage as Baron Monkswell in 1885. He was a man of many accomplishments, and especially distinguished as an amateur painter, frequently exhibiting landscapes at the Royal Academy and elsewhere. In his younger days he had been noted as a clever caricaturist. He was succeeded in the peerage by his elder son, Robert (b. 1845), who, after taking a first class in law at Cambridge, went to the bar, and became (1871) conveyancing counsel to the treasury, and (1885–1886) an official examiner of the High Court, and, taking to politics as a Liberal, under-secretary for war (1895). The younger son, John Collier (b. 1850), inherited his father's artistic tastes, and became a well-known painter.

MONLUC, or MONTLUC, the name of a French family. The house of Lasséran-Mansencomme, which possessed the estate of Monluc in Agenais, and took its name in the 16th century, is held to be a branch of the family of Montesquiou. Marshal Blaise de Monluc (d. 1577), author of the *Commentaires*, had a son, Pierre Bertrand, called the Capitaine Peyrot, who perished in an expedition to Madeira in 1566, and another son, Fabien de Monluc, whose granddaughter, Jeanne de Monluc (d. 1657), countess of Carmaing, princess of Chabanais, brought the estates of her house to the family of Escoubleau by her marriage with Charles d'Escoubleau, marquess of Sourdis and Alluyes. Jean de Monluc, brother of the marshal, was bishop of Valence and Die, and distinguished himself in several embassies. He died in 1579, leaving a natural son, Jean de Monluc (d. 1603), seigneur de Balagny, who was at first a zealous member of the League, but made his submission to Henry IV., and received from him the principality of Cambrai and the bâton of a marshal of France.

MONMOUTH, JAMES SCOTT, DUKE OF (1649–1685), leader of his abortive insurrection against James II. in 1685, was the son of Lucy Walters, "a brown, beautiful, bold but insipid creature," who became the mistress of Charles II. during his exile at the Hague. He was born at Rotterdam on the 9th of April 1649. That Charles was his father is more than doubtful, for Lucy Walters had previously lived with Robert Sidney (son of the earl of Leicester), brother of Algernon, and the boy resembled him very closely. Charles, however, always recognized him as his son, and lavished on him an almost doting affection. Until the Restoration he was placed under the care, first of Lord Crofts, by whose name he was known, and then of the queen-dowager, receiving his education to the age of nine from Roman Catholics, but thenceforward from Protestant tutors. In July 1662 he was sent for by Charles, and at thirteen was placed under the protection of Lady Castlemaine and in the full tide of the worst influences of the court. No formal acknowledgment of his relation to the king was made until his betrothal to Anne Scott, countess of Buccleuch, the wealthiest heiress of Scotland, whom he married in 1665. During 1663 he was made duke of Orkney, duke of Monmouth and knight of the Garter, and received honorary degrees at both universities; and on his marriage he and his wife were created duke and duchess of Buccleuch, and he took the surname of Scott. At court he was treated as a prince of the blood. In 1665 he served with credit under the duke of York in the sanguinary naval battle off Lowestoft. A captaincy in the Life Guards was given him, and in 1670, on the death of Monk, he was made captain-general of the king's forces. In 1670 Monmouth was with the court at Dover, and it is affirmed by Reresby that the mysterious death of Charles's sister, Henrietta, duchess of Orleans, was due to her husband's revenge on the discovery of her intrigue with the duke. It is certain, from an entry by Pepys, that as early as 1666 he had established a character for vice and profligacy. He was the direct author of the attack in December 1670 on Sir John Coventry, and only a few months later received the royal pardon for his share in the wanton murder of a street watchman.

Hitherto Monmouth had been but the spoiled child of a wicked court. Now, however, by no act or will of his own, he began to be a person politically important. As early as 1662 the king's excessive fondness for him had caused anxiety. Even then the fear of a "difference" between Monmouth and James, duke of York, exercised men's minds, and every caress or promotion kept the fear alive. Who could tell but that, in default of legitimate issue from his queen, Charles might declare Monmouth himself his lawful son? A civil war would be the certain consequence. Soon after 1670 the matter took a more serious aspect. The anti-popery spirit was rapidly becoming a frenzy, and the succession of James a probability and a terror. Charles was urged to legitimize Monmouth by a declaration of his marriage with Lucy Walters. He returned answer that, much as he loved the duke, he would rather see him hanged at Tyburn than own him for his legitimate son. Every attempt, however, was henceforth made, especially by Shaftesbury, to accustom people to this idea, and his position was emphasized by James's second marriage, with the Roman Catholic princess Mary of Modena. From this time his popular title was "the Protestant duke." In 1674 he was made "commander-in-chief"; and in connexion with this another unsuccessful attempt, graphically described in Clarke's *Life of James*, was made to gain from Charles a tacit admission of his legitimacy. At Shaftesbury's instance he was placed in command of the army employed in 1675 against the Scottish Covenanters, and was present at Bothwell Bridge (June 22, 1679). In 1678, when Charles was driven into war with Louis, Monmouth took the command of the English contingent, and again gained credit for personal courage at the battle of St Denis. On his return to London England was in the throes of the popish terror. The idea of securing the Protestant succession by legitimizing Monmouth again took shape and was eagerly pressed on by Shaftesbury; at the time it seemed possible that success would wait on the audacity.

The pensionary parliament was dissolved in January 1678–1679, and was succeeded by one still more determined in its anti-popery spirit. To avoid the storm, and to save, if possible, his brother's interests, Charles instructed him to leave the country. James retired to Brussels, the king having previously signed a declaration that he "never was married, nor gave contract to any woman whatsoever but to my wife Queen Catherine." In the summer of 1679 the king suddenly fell ill, and the dangers of a disputed succession became terribly apparent. The party opposed to Monmouth, or rather to Shaftesbury, easily prevailed upon Charles to consent to his brother's temporary return. When, after the king's recovery, James went back to Brussels, he received a promise that Monmouth too should be removed from favour and ordered to leave the country. Accordingly, in September 1679, the latter repaired to Utrecht, while shortly afterwards James's friends so far gained ground as to obtain for him permission to reside at Edinburgh instead of at Brussels. Within two months of his arrival at Utrecht Monmouth secretly returned to England, arriving in London on the 27th of November. Shaftesbury had assiduously kept alive the anti-popery agitation, and Monmouth, as the champion of Protestantism, was received with every sign of popular delight. The king appeared to be greatly incensed, deprived him of all his offices, and ordered him to leave the kingdom at once. This he refused to do, and the only notice taken of the disobedience was that Charles forbade him to appear at court.

It was at this time that the *Appeal from the Country to the City*, written by Ferguson, was published, in which the legitimacy was tacitly given up, and in which it was urged that "he that hath the worst title will make the best king." Now it was, too, that the exclusionists, who in the absence of parliament were deprived of their best basis for agitation, developed the system of petitioning. So promptly and successfully was this answered by the "abhorrers" that Charles, feeling the ground safer under him, recalled James to London—a step immediately followed by the resignation of the chief Whigs in the council.

Once more, however, a desperate attempt was made, by the fable of the "black box," to establish Monmouth's claims; and once more these claims were met by Charles's public declarations in the *Gazette* that he had never been married but to the queen. Still acting under Shaftesbury's advice, Monmouth now went upon the first of his progresses in the west of England, visiting the chief members of the country party, and gaining by his open and engaging manner much popularity among the people. In August 1680 James returned to Edinburgh, his right to the succession being again formally acknowledged by Charles. Monmouth at once threw himself more vehemently than ever into the plans of the exclusionists. He spoke and voted for exclusion in the House of Lords, and used language not likely to be forgotten by James when an opportunity should come for resenting it. He was ostentatiously feasted by the city, the stronghold of Shaftesbury's influence; and it was observed as he drove to dinner that the mark of illegitimacy had been removed from the arms on his coach.

The year 1681 seemed likely to witness another civil war. The parliament finished a session of hysterical passion by passing a series of resolutions of extreme violence, of which one was that Monmouth should be restored to all his offices and commands; and when Charles summoned a fresh parliament to meet at Oxford the leaders of the exclusionists went thither with troops of armed men. Not until the dissolution of this last parliament, on the 27th of March 1681, did the weakness of Monmouth's cause appear. The deep-seated respect for legitimate descent asserted itself, and a great reaction took place. In November Dryden published *Absalom and Achitophel*. Shaftesbury was attacked, but was saved for the time by a favouring jury. Monmouth himself did not escape insult in the street and from the pulpit. He was forbidden to hold communication with the court; and when he went, in September 1682, on a second progress through the western and north-western counties his proceedings were narrowly watched, and he was at length arrested at Stafford. Severity and extreme lenity were strangely mingled in the treatment he received. He was released on bail, and in February 1683, after the flight and death of Shaftesbury, he openly broke the implied conditions of his bail by paying a third visit to Chichester with Lord Grey and others on pretence of a hunting expedition.

It is probable that Monmouth never went so far as to think of armed rebellion; but there is little doubt that he had talked over schemes likely to lead to this, and that Shaftesbury had gone farther still. The Rye House plot gave an excuse for arresting the Whig leaders; Russell and Sidney were judicially murdered; Monmouth retired to Toddington, in Bedfordshire, and was left untouched. Court intrigue favouring him, he succeeded, by the betrayal of his comrades and by two submissive letters, in reconciling himself with the help of Halifax both to the king and to James, though he had the humiliation of seeing his confessions and declarations of penitence published at length in the *Gazette*. His character for pettishness and folly was thus amply illustrated. Charles heartily despised him, and yet appears to have retained affection for him. His partial return to favour raised the hopes of his partisans; to check these, Algernon Sidney was executed. Monmouth was now subpoenaed to give evidence at the trial of young Hampden. To escape from the difficulties thus opened before him he fled to Holland, probably with Charles's connivance, and though he once more, in November 1684, visited England, it is doubtful whether he ever again saw the king.

The quiet accession of James II. soon brought Monmouth to the crisis of his fate. Within two months of Charles's death he had yielded to the impetuosity of Argyll and others of the exiles and to vague invitations from England. It is curious, as showing the light in which his claims were viewed by his fellow-conspirators, that one of the terms of the compact between them was that, though Monmouth should lead the expedition, he should not assume the title of king without their consent, and should, if the rebellion were successful, resign it and accept whatever rank the nation might offer. Now, as always, he was but a puppet in other men's hands.

On the 2nd of May Argyll sailed with three ships to raise the west of Scotland; and three weeks later, with a following of only eighty-two persons—of whom Lord Grey, Fletcher of Saltoun, Wade, and Ferguson, the author of the *Appeal from the Country to the City*, were the chief—Monmouth himself set out for the west of England, where, as the stronghold of Protestant dissent and as the scene of his former progresses, he could alone hope for immediate support. Even here, however, there was no movement; and when on the 11th of June Monmouth's three ships, having eluded the royal fleet, arrived off Lyme Regis, he landed amid the curiosity rather than the sympathy of the inhabitants. In the market-place his "declaration," drawn up by Ferguson, was read aloud. In this document James was painted in the blackest colours. Not only was he declared to be the murderer of Essex, but he was directly charged with having poisoned Charles to obtain his crown. Monmouth soon collected an undisciplined body of some 1500 men, with whom he seized Axminster, and entered Taunton. Meanwhile the parliament had declared it treason to assert Monmouth's legitimacy, or his title to the crown; a reward of £5000 was offered for him dead or alive, and an act of attainder was passed in unusual haste. Troops had been hurriedly sent to meet him, and when he reached Bridgwater Albemarle was already in his rear. From Bridgwater the army marched through Glastonbury to attack Bristol, into which Lord Feversham had hastily thrown a regiment of foot-guards. The attempt, however, miscarried; and, after summoning Bath in vain, Monmouth, with a disordered force, began his retrograde march through Philips Norton and Frome, continually harassed by Feversham's soldiers. At the latter place he heard of Argyll's total rout in the western Highlands. He was now anxious to give up the enterprise, but was overruled by Grey, Wade and others. On the 3rd of July he reached Bridgwater again, with an army little better than a rabble, living at free quarters and behaving with reckless violence. On Sunday, the 5th, Feversham entered Sedgemoor in pursuit; Monmouth the same night attempted a surprise, but his troops were hopelessly routed. He himself, with Grey and a few others, fled over the Mendip Hills to the New Forest, hoping to reach the coast and escape by sea. The whole country, however, was on the alert, and at midnight on the 8th, within a month of their landing, James heard that the revolt, desperate from the first, was over and that his rival had been captured close to Ringwood in Hampshire.

On the day of his capture Monmouth wrote to James in terms of the most unmanly contrition, ascribing his wrong-doings to the action of others, and imploring an interview. On the 13th the prisoners reached the Tower, and on the next day Monmouth was allowed to see James. No mercy was shown him, nor did he in the least deserve mercy; he had wantonly attacked the peace of the country, and had cruelly libelled James. The king had not, even in his own mind, any family tie to restrain him from exercising just severity, for he had never believed Monmouth to be the son of any one but Robert Sidney. Two painful interviews followed with the wife for whom he bore no love, and who for him could feel no respect; another imploring letter was sent to the king, and abject protestations and beseechings were made to all whom he saw. He offered, as the last hope, to become a Roman Catholic, and this might possibly have proved successful, but the priests sent by James to ascertain the sincerity of his "conversion" declared that he cared only for his life and not for his soul.

He met his death on the scaffold with calmness and dignity. In the paper which he left signed, and to which he referred in answer to the questions wherewith the busy bishops plied him, he expressed his sorrow for having assumed the royal style, and at the last moment confessed that Charles had denied to him privately, as he had publicly, that he was ever married to Lucy Walters. He died at the age of thirty-six, on the 15th of July 1685.

Monmouth had four sons and two daughters by his wife, who in 1688 married the 3rd Lord Cornwallis and died in 1732. The elder of the two surviving sons, James, earl of Dalkeith (1674–1705) had a son Francis (1695–1751), who through his grandmother inherited the title of duke of Buccleuch in 1732, and was the ancestor of the later dukes. The younger son, Henry (1676–1730), was created earl of Deloraine in 1706, and rose to be a major-general in the army.

The best accounts of Monmouth's career, apart from the modern histories, are G. Roberts's detailed *Life* (1844), the articles in the *Dict. Nat. Biog.* (by A. W. Ward) and in Collins's *Peerage*, and the *Correspondence of Lord Clarendon with James, earl of Abingdon*, 1683–1685 (Clarendon Press, 1896). For the rebellion, Lord Grey's *Secret History* (1754) should be consulted. See also Evelyn's and Pepys's *Diaries*, &c.

MONMOUTH, ROBERT CAREY, 1ST EARL OF (*c.* 1560–1639), youngest son of Henry Carey, 1st Baron Hunsdon, chamberlain and first cousin of Queen Elizabeth, by Anne, daughter of Sir Thomas Morgan, of Arkestone in Herefordshire, was born about the year 1560. As a young man he accompanied several diplomatic missions abroad and took part in military expeditions. In 1587 he joined in the attempt to relieve Sluys, in 1588 served as a volunteer against the Spanish expedition, and commanded a regiment in Essex's expedition to Normandy in 1591, taking part in the siege of Rouen. He was knighted by Essex the same year for having by his intercession with the queen procured his recall. In the parliaments of 1586 and 1588 he represented Morpeth; in that of 1593, Callington; and in those of 1596 and 1601, Northumberland. From 1593 till the end of Elizabeth's reign he occupied various posts in the government of the Scottish borders, succeeding to his father's appointment of lord warden of the marches in 1596, which he held till February 1598. In March 1603 he visited the court, and witnessed the queen's last illness, which he described in his *Memoirs*. Anxious to recommend himself to her successor, and disobeying the orders of the council, he started on horseback immediately after the queen's death on the morning of the 24th of March, in order to be the first to communicate the tidings to James, arrived at Holyrood late on the 26th, and was appointed by the king a gentleman of the bedchamber. But his conduct met with general and merited censure as "contrary to all decency, good manners and respect," and on James's arrival in England he was dismissed from his new post. On the 23rd of February 1605, however, he was made governor of Prince Charles, in 1611 his master of the robes, in 1617 his chamberlain, and on the 6th of February 1622, he was created Baron Carey of Leppington. In 1623 he followed Charles to Spain, and after the latter's succession to the throne he was created earl of Monmouth in 1626. He died on the 12th of April 1639. His eldest son HENRY (1596–1661), succeeded him as 2nd earl of Monmouth, and on his death without surviving male issue the peerage became extinct.

His *Memoirs* were published first by the earl of Cork and Orrery in 1759, a new edition, annotated by Sir Walter Scott, being printed in 1808.

MONMOUTH (Welsh *Mynwy*), a municipal and contributory parliamentary borough, and the county town of Monmouthshire, England, 18 m. S. of Hereford, on the Great Western railway. Pop. (1901), 5095. It is picturesquely situated at the confluence of the Wye and the Monnow, between the two rivers, and is almost surrounded by hills. Portions of the town walls remain, and there is a picturesque old gateway on the Monnow bridge; but there are only insignificant ruins of the castle, which was originally a Saxon fortress, and was twice taken by the Parliamentary forces during the Civil War. Besides the churches—that of St Mary, completed in 1882 on an ancient site, and the chapel of St Thomas, a late Norman structure—the principal buildings are the town-hall, the Rolls Hall and the free grammar-school, which was founded in 1614, and educates about 150 boys on the usual lines of a public school. A statue of Henry V., who was born in its castle, stands in the market-place. With Newport and Usk, Monmouth forms the Monmouth parliamentary district of boroughs, returning one member.

Monmouth (*Monemuta*) from the coincidence of position is supposed to be the *Blaestium* of Antoninus. Situated between the Severn and the Wye its strategic importance was early recognized by the Saxons, who fortified it against the Britons, while in later years it played a leading part in Welsh border warfare. At the time of the Domesday Survey the castle was in the custody of William Fitz Baderon. Henry III. granted it, together with the lordship of the borough, to his son Edmund Crouchback, through whose descendants both borough and castle passed into the duchy of Lancaster. Since the 18th century the dukes of Beaufort have been lords of the borough. Monmouth was a borough by prescription as early as 1256, and was governed by a mayor in 1461, but was not incorporated until 1550 under the title of "Mayor, Bailiffs and Commonalty." This charter was confirmed in 1558, 1606 and 1666, a recorder and town clerk being added to the constitution. In accordance with the act of 1535–1536 Monmouth as county town obtained the right of representation in parliament; the earliest returns existing are for 1553, since which date one member has been returned regularly. Wednesday and Saturday markets were confirmed to Monmouth in 1550, with the further proviso that no others were to be held within five miles of the borough. Friday is now the weekly market-day. At the same time an annual three-days' fair, which still exists, was granted on Whit-Tuesday and successive days. During the 16th and 17th centuries the manufacture of Monmouth caps was an important industry, fostered by legislation and mentioned by Fuller in his *Worthies of England*.

See Charles Heath, *The Town of Monmouth* (Monmouth, 1804).

MONMOUTH, a city and the county-seat of Warren county, Illinois, in the W. part of the state, about 40 m. S. of Rock Island. Pop. (1890), 5936; (1900), 7460, (594 foreign-born); (**1910**), **9128**. It is served by the Chicago, Burlington & Quincy and the Iowa Central railways, and by electric railways to Galesburg and to Rock Island. The city is the seat of Monmouth College (1856; United Presbyterian), which in 1908 had 28 instructors and 454 students. Among the public buildings and institutions are the county court-house, the federal building, a hospital and the Warren county library (1836). Monmouth is situated in a good farming region, and cattle, swine and ponies are raised in the vicinity. The city has various manufactures. Monmouth was settled about 1824, first incorporated as a village in 1836, chartered as a city in 1852 and in 1882 reorganized under a general state law.

MONMOUTH, BATTLE OF (1778), a battle in the American War of Independence. The prospect of an alliance between France and America in 1778 induced the British to concentrate their forces. Sir Henry Clinton, who had succeeded Sir W. Howe in command, determined to abandon Philadelphia, captured in the previous year, and move his troops direct to New York through New Jersey. Washington, who had spent the winter at Valley Forge, Pennsylvania, and had materially recruited his army, immediately marched to intercept the British, and overtook them near Monmouth Court House (now Freehold), New Jersey, on the 28th of June 1778. A strong detachment of Americans under General Charles Lee was sent forward to harass the enemy's rear and if possible cut off a portion of their long baggage train. Clinton strengthened his rearguard, which turned upon the Americans and compelled them to retreat. When Washington, who was well up with his main body, heard of Lee's retreat, he spurred forward and exerted himself in forming a strong line of battle in case the British continued their determined attack. Warm words passed between Washington and Lee, which subsequently led to the latter's court-martial and suspension for a year. The readjusted American line was composed of the divisions of Lafayette, Greene, Alexander and Patterson, while Wayne's brigade, which had been in Lee's advance from the first, was posted in a favourable position. The British attacked this line and a warm, though brief, engagement ensued. Both sides encamped at night on the ground occupied. The British, having accomplished their object in delaying Washington's pursuit, continued their march the next day towards New York. Washington turned to the left, crossed the Hudson above, and encamped for the remainder of the season at White Plains, New York, within striking distance of the city. Each side suffered about the same loss in the battle, that of the British being 400 (60 due to sunstroke), the American somewhat less. In this engagement Lieut.-Colonel Henry Monckton (1740–1778) of the British Grenadiers was killed in leading a charge.

MONMOUTHSHIRE, a western border county of England, bounded E. by Gloucestershire, N. E. by Herefordshire, N.W. by Brecknock, W. and S.W. by Glamorganshire (Wales), and S. by the estuary of the river Severn. The area is 534 sq. m. The surface is varied, and in many districts picturesque, especially along the valley of the Wye, and between that river and the Usk. In the west and north the hills rise to a considerable height, and this mountain region encircles a finely undulating country. The highest summits are Sugar Loaf (1955 ft.), Blorenge (1838), and Skirrid Fawr (1601), summits of the hills which almost encircle the town of Abergavenny. On the other hand, along the shore of the Severn estuary on either side of the Usk, are two extensive tracts of marshland, called the Caldicot and Wentlloog levels, stretching from Cardiff to Portskewet, and protected from inundations by strong embankments. The principal rivers are the Wye, which forms the greater part of the eastern boundary of the county with Gloucestershire, and falls into the Severn; the Monnow, which forms a portion of its boundary with Herefordshire, and falls into the Wye at the town of Monmouth; the Usk, which rises in Brecknock, and flows southward through the centre of the county; the Ebbw, which rises in the north-west, and enters the estuary of the Usk below Newport; and the Rhymney, which rises in Brecknock, and, after forming the boundary between Monmouth and Glamorgan, enters the Bristol Channel a little east of Cardiff. Salmon abound especially in the Wye and the Usk, and trout are plentiful in many of the streams.

Geology.—The oldest rocks in the county are the Silurian strata (Wenlock Shale and Limestone, and Ludlow Beds) which form an extensive anticline at Usk; a smaller inlier appears at Rumney on the south-west borders of the county near Cardiff. These beds dip under the Old Red Sandstone, a great series of red marls, sandstones and concretionary limestones (cornstones) which occupies the north-eastern part of the county; the highest beds contain grits and conglomerates which give rise to bold escarpments and lofty plateaux (*e.g.* the Sugar Loaf and Skirrid Fawr) alongside the outcrop of the Carboniferous Limestone. The western part of the county, between Pontypool and the river Rhymney, is occupied by the eastern end of the great South Wales coal-field, where the Carboniferous Limestone, Millstone Grit and Coal Measures (Lower Coal Series, Pennant Sandstone and Upper Coal Series) dip westward and succeed each other from east to west. The Coal Measures abound in coal-seams and ironstone, and their densely populated valleys offer a marked contrast to the agricultural and pastoral districts of the rest of the county. The Carboniferous Limestone comes in again in the south-east near Chepstow, and has imparted its characteristic scenery to the lower reaches of the Wye. After a prolonged interval, during which these older formations were folded, faulted, upheaved and finally carved by erosion into hills and valleys, the southern portion of the region was submerged beneath the waters of the Triassic lake in which the Keuper Marls were deposited. These consist of red conglomerates and marls which wrap round the heights and fill up the hollows among the older rocks to the south-west of Chepstow, and the subsidence continuing, admitted the waters of the Jurassic sea which deposited the fossiliferous Rhaetic and Lias limestones and shales of Llanwern and Goldcliff near Newport. Glacial gravel and boulder-clay are found in the valleys and a broad tract of alluvium borders the shores of the Bristol Channel.

Agriculture.—Along the Severn shore the soil is deep and loamy, and admirably suited for the growth of trees. The most fertile land is that resting on the Red Sandstone, especially along the banks of the Usk, where wheat of fine quality is raised. In the mountainous regions more attention is paid to grazing than to the raising of crops. There are a considerable number of dairy farms, but sheep-farming is much more largely followed. Only about seven-tenths of the total area of the county is under cultivation. There is a large extent of hill pasture, and a considerable acreage under orchards.

Mining.—The coal-mines and iron-works which Monmouthshire shares with South Wales are very important. They occur in the wild and mountainous western part of the county, where a series of upland valleys, running parallel from N.N.W. to S., has each its populous mining townships and railways, which have in many cases necessitated remarkable engineering works—such as the great Crumlin viaduct. These valleys, in order from east to west, with the principal townships in each, are as follows: Afon Lwyd (Panteg, Pontypool, Abersychan and Blaenavon); Ebbw Fach (Abertillery, Nantyglo and Blaina), joining the Ebbw (Risca, Ebbw Vale); Sirhowy (Bedwellty and Tredegar); Rhymney (New Tredegar and Rhymney). Besides coal, a considerable quantity of fire-clay and some iron are raised.

Communications.—The principal railway serving the county is the Great Western, but in the mining districts there are also various branches of the London and North-Western, Rhymney and Brecon and Merthyr systems. The Crumlin Canal from the Ebbw Valley, and the Monmouthshire Canal from Pontypool converge upon Newport, which is the principal port in the county. The Brecon Canal runs north from Pontypool into the valley of the Usk.

Population and Administration.—The area of the ancient county is 341,688 acres, with a population in 1891 of 252,416, and in 1901 of 292,317. The area of the administrative county is 349,712 acres. The county comprises 6 hundreds. The municipal boroughs are Abergavenny (pop. 7795), Monmouth (5095), and Newport, a county borough (67,270). The following are urban districts: Abercarn (12,607), Abersychan (17,768), Abertillery (21,945), Bedwellty (9988), Blaenavon (10,869), Caerleon (1367), Chepstow (3067), Ebbw Vale (20,994), Llanfrechfa, Upper (2979), Llantarnam (5287), Mynyddislwyn (3337), Nantyglo and Blaina (13,489), Panteg (7484), Pontypool (6126), Rhymney (7915), Risca (9661), Tredegar (18,497), and Usk (1476). Monmouthshire is in the Oxford circuit, and assizes are held at Monmouth. It has one court of quarter sessions, and is divided into 11 petty sessional divisions. The boroughs of Monmouth and Newport have commissions of the peace, but no separate court of quarter sessions. The parliamentary divisions are the northern, western and southern, each returning one member; and the Monmouth district of parliamentary boroughs, consisting of the towns of Monmouth, Newport and Usk, returns one member.

History.—The district which is now Monmouthshire formed the Welsh kingdom of Gwent at the time of the Heptarchy, and, owing to the extraordinary courage of the Gwentians in resisting the repeated inroads of the Saxons, no permanent English settlement was effected in the district until close upon the middle of the 11th century. The incursions of the West Saxons began in the 7th century, and, during the reign of Alfred, Brochmael and Fermael, kings of Gwent, acknowledged Alfred as their lord, and sought his protection against their enemies. In the 9th and 10th centuries the district was frequently harried by the Danes, who in 915, under Ohter and Hwald, sailed round Wessex and Cornwall to the mouth of the Severn and plundered all along the banks of the Wye, finally taking prisoner the bishop of Llandaff, whom they only released on a ransom of £40. In 926 Æthelstan obliged the kings of the north Britons to meet him at Hereford and fixed the Wye as the limit of their territory. In 976 the Danes destroyed Caerleon, at this time the chief town of the district. The early 11th century was taken up with a series of interminable contests between the Welsh princes for the succession in South Wales, as a result of which the Welsh Chronicle relates that in 1047 the whole of South Wales lay waste, and in 1049, when a fleet of Irish pirates entered the Severn estuary, Griffith, the king of South Wales, assisted them in plundering the neighbourhood. In 1065 Harold conquered the whole district between the lower reaches of the Wye and the Usk, and gave orders for the construction of a hunting-box at Portskewet for Edward the Confessor, but very shortly after Caradoc ap Griffith, with a large body of followers, killed all the workmen engaged in the building and carried away the provisions prepared for the king's reception.
